BEFORE THE BOARD OF ENVIRONMENTAL REVIEW
OF THE STATE OF MONTANA

IN THE MATTER OF: **APPEAL AMENDMENT AM4,** **WESTERN ENERGY COMPANY,** **ROSEBUD STRIP MINE AREA B** **PERMIT NO. C198400B**	**CASE NO. BER 2016-03 SM** **AFFIDAVIT OF ALEXIS BONOGOFSKY IN SUPPORT OF PLAINTIFF'S MOTION FOR SUMMARY JUDGMENT**

I, Alexis Bonogofsky, hereby declare:

1. I am over eighteen (18) years old, I am competent to testify, and have personal knowledge of the matters set forth herein.
2. I am a fourth generation Montanan and I live at 2020 Tired Man Road, south of Billings, MT on the Yellowstone River on my family's farm and ranch. My partner and I operate Blue Creek Boers, a meat operation. My family has farmed and ranched since they homesteaded in Montana over 100 years ago. In addition, I am a fellow with the Lannan Foundation. In this capacity, I write about politics and energy issues mostly centered around southeastern Montana and document eastern Montana landscapes with photography. Previously, I was the Tribal Lands Program Manager for the National Wildlife Federation. In that capacity, I worked with Tribes on issues ranging from energy issues such as coal, oil and gas, to bison restoration on tribal lands. I continue to work with the Northern Cheyenne tribal community on climate change issues and on environmental issues including water and air pollution related to energy production and development. In addition, I also work with ranchers in southeast Montana on these same issues. Because of my work and personal relationships with the tribe and ranchers, I travel frequently, sometimes up to once or twice a week, to the Colstrip and Lame Deer areas. I am also a big game and upland bird hunter. I do the majority of big game hunting at the L&L Ranch, approximately 17 miles south Colstrip. This is the place where I shot my first mule deer and for over three years I have pursued elk, mule deer, and antelope on this ranch and plan to do so every year that

conditions allow in the future. Hunting is a way of life for me, as I grew up hunting with my mother and father. Hunting provides food for my partner and myself throughout the year. The L&L Ranch is an amazing place for high quality hunting opportunities and provides us with a unique experience that you cannot find anywhere else in Montana. You cannot step a foot in any direction without seeing amazing natural beauty and history of the American West. We are planning to hunt on the L& L this coming fall.

3. I have been a member of the MEIC since October 2012, and currently serve on the Board of Directors. MEIC is a nonprofit corporation founded in 1973 by Montanans concerned about protecting and restoring Montana's natural environment. MEIC has worked extensively on addressing the impacts of air pollution in Montana. I have also been a member of the Sierra Club since 2009. The Sierra Club is the nation's oldest grassroots conservation organization, founded in 1892. The Sierra Club is waging a national campaign to both hold polluters in the coal industry accountable and to speed the nations transition to cleaner fuels. These efforts extend to Montana.
4. As a hunter, I spend on average 3 to 5 days pursuing big game on the L&L. I spend at least 60 additional days a year in and around Colstrip and Lame Deer, Montana. During my trips to the Colstrip area, I have occasionally seen from a distance the mining operations occurring at the Rosebud mine. This is concerning for me, as I'm aware of the impacts of coal strip mining to the ecology and water quality of southeastern Montana.

5. Growing up on the ranch on the Yellowstone River, I was taught that the land provides for us and we, in turn, need to protect the land. I grew up eating almost exclusively wild game that my family hunted and vegetables that we grew on our farm. Recently, an Exxon oil pipeline ruptured underneath the Yellowstone River and our land was flooded with oil. That disaster has impacted our land greatly and has shown me what pollution can do to the wildlife, plants and livestock that we raise and my own health. It has been devastating to our operation. I am on the Board of the national organization Pipeline Safety Trust. I grew up living around three oil refineries and a coal fired power plant in Billings. The air pollution from these sources impacts the air quality in our region and water quality in the Yellowstone River. I personally have been impacted by environmental pollution my whole life, and now work to protect other people and wildlife from the effects of pollution.
6. I am deeply concerned about the water pollution from the Rosebud Coal mine and its potential impacts on the health of the land and the wildlife that I hunt on the L&L ranch. I believe that the pollution from the Rosebud Coal mine is the major source of water pollution directly north of the area where I annually hunt. I'm aware that the segment of East Fork Armells Creek that flows north from Colstrip is considered an impaired water body by the Montana Department of Environmental Quality. This impairment is due to elevated levels nitrate plus nitrite, electrical conductivity, total dissolved solids, and total Kjehldahl nitrogen. The DEQ has listed coal mining as a probable source of impairment.

7. The L&L Ranch is characterized by large sandstone rock formations flanked by shortgrass prairie and large buttes dominated by pine forests. Besides Rosebud Creek, which is the eastern boundary of the ranch, there is little surface water on the property.
8. Southeastern Montana is a semi-arid climate and therefore existing streams, creeks and wetland areas are extremely important to wildlife that live in the area. Any surface water is an extremely valuable resource in southeastern Montana and necessary to sustain the high quality hunting opportunities that southeast Montana offers. Any impacts to water, whether it is a spring drying up or the discharge of pollution, impacts the wildlife resource.
9. I am concerned and worried that the deer, antelope and elk that I hunt on the L&L are exposed to pollution from the Rosebud mine when they drink out of East Fork Armell's Creek and Rosebud Creek, which is just north and northeast of the ranch that I hunt on, and that pollution impacts their health and, in turn, my health. I am also concerned that they suffer from degraded habitat caused by the strip mine.
10. I am extremely concerned about the toxins being exposed to the wildlife that I eat. We know that wildlife pick up toxins from pollution in the water, and to my knowledge, there have not been studies conducted on the wildlife that live in and around the Rosebud mine.
11. Improving the water quality in the region I work and hunt in will have a positive impact on my health, my family's health, my work, my hunting

opportunities, and my ability to view the scenic vistas and landscapes in southeastern Montana.

12. I declare under penalty of perjury that the foregoing is true and correct.

P.O. Box 99
138 Rosebud Lane
Colstrip, MT 59323-0099

Permit ID: C1984003B
Revision Type: Amendment
Permitting Action: Deficiency
Subject: AM4, Sixth Round Acceptability Deficiency

Dear Dicki:

The Department of Environmental Quality (DEQ) has completed its acceptability review regarding Western Energy Company's application for Amendment AM4. The following deficiencies must be adequately addressed before DEQ can determine the application acceptable:

ARM 17.24.314(3):

Please provide more detail on the surface water model used to create tables G-1, G-2, G-3, and G-5. Specifically, state the inputs to the model that were used and how they were calculated. A map or a reference to an exhibit in the permit is also needed as it is unclear how many sub-basins were used, how the streams for the model were calculated or which streams were used, and how the model was constructed. An example can be provided upon request.

The explanation as to why Areas A, B, and C can be analyzed separately from Areas E and D should be included in the text of the PHC.

P. 36 Section 4.2.4.1 General Water Quality Evaluation: A statement was added to the revised PHC determination that states: "A sample is considered to represent baseline conditions if it was collected before mining approached within 0.5 miles. There were no samples meeting this criterion for overburden, interburden and sub-McKay wells, as mining started in 1975." Although not numerous, there are water quality samples for these units that were collected and analyzed prior to encroachment of mining within a half-mile. Please check to confirm the statement in the PHC is accurate.

Figure 23A, Simulated Potentiometric Heads, Pre-Mine Conditions still has the proposed Area F permit outline on it. The data may be used, but the permit outline must be deleted.

As a suggestion for future documents, a list of acronyms or introduction of the terms an acronym represents (e.g. PHC, TDS) during its first use in a document would be helpful to a reader

unfamiliar with commonly used permit acronyms. The acronym "PHC" appears to be used to represent the probable hydrologic consequences *determination* as well as probable hydrologic consequences of mining and causes confusion. In future documents please use "PHC" to represent the probable hydrologic consequences determination, as that is the most common use of the acronym.

Upon receipt of satisfactory responses to these deficiencies, DEQ will determine the application to be acceptable.

Please feel free to contact Robert D. Smith at 406-444-7444 with questions regarding this letter.

Sincerely,

Chris Yde, Supervisor
Coal and Uranium Program

Ms. Dicki Peterson
Western Energy Company
Rosebud Coal Mine Area B
P.O. Box 99
138 Rosebud Lane
Colstrip, MT 59323-0099

Permit ID: C1984003B
Subject: PHC for AM4 (Amendment Application 184)

Dear Dicki :

Per your request, this letter summarizes the outcome of our phone conversation Tuesday morning (April 30, 2013) between DEQ staff, Western Energy staff, and your hydrology consultant, Michael Nicklin, regarding the PHC necessary to complete review of AM4 (Amendment Application 184).

The PHC needs to comprehensive for areas A, B, and C. The PHC should include analysis of potential hydrologic impacts for all permitted mining in Rosebud Mine areas A, B, and C, as well as the proposed cuts in Area B (AM4). There is no need to complete PHC's for individual areas, as the Rosebud Mine as a whole needs to have a single comprehensive analysis for all surface water and groundwater impacts. The proposed cuts associated with currently unapproved minor revisions for Area A should not be included.

Any deficiencies identified after review in the PHC will be included in the next AM4 response letter.

Please feel free to contact me if questions remain or if I failed to consider some aspect of our conversation.

Sincerely,

Chris Yde, Supervisor

Attorneys for Respondent Department of Environmental Quality

MONTANA BOARD OF ENVIRONMENTAL REVIEW

IN THE MATTER OF: **APPEAL AMENDMENT AM4 WESTERN ENERGY COMPANY ROSEBUD STRIP MINE AREA B, PERMIT NO. C1984003B**	Case No.: BER 2016-03 SM RESPONDENT'S RESPONSES TO PETITIONER'S SECOND SET OF REQUESTS FOR ADMISSION, INTERROGATORIES AND REQUESTS FOR PRODUCTION

Respondent, Department of Environmental Quality ("DEQ") responds to PETITIONER'S SECOND SET OF REQUESTS FOR ADMISSION, INTERROGATORIES AND REQUESTS FOR PRODUCTION as follows:

DISCOVERY REQUESTS

REQUEST FOR ADMISSION NO. 44: You are requested to admit that proposed Area F operations will impact water quality and water quantity in the Rosebud Coal seam. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ objects to this discovery request as argumentative to the extent that it requires the assumption that the deficiencies identified by DEQ in WECO's Area F application

Exhibit 16

will be resolved and that Area F operations will proceed as proposed. DEQ further objects to this discovery request on the grounds of relevance. This discovery request seeks information not relevant to the subject matter of this appeal and not reasonably calculated to lead to the discovery of admissible evidence. DEQ has already stated in response to Petitioner's First Set of Discovery Requests, Interrogatory No. 13, that DEQ justified its decision not to include Area F within the CHIA because "[t]he proposed action was determined to have no impacts to mine Area C making it unnecessary to include Area F," and cited to those specific portions of the CHIA that support its conclusion (See DEQ's Answer to Interrogatory No. 13). Without waiving its objections, DEQ admits that if WECo's Area F permit application is approved and operations proceed in Area F as proposed, proposed Area F operations will have an impact on water quality and quantity in the Rosebud Coal seam, but consideration of these impacts were not relevant to preparation of the CHIA for Amendment AM4.

REQUEST FOR ADMISSION NO. 45: You are requested to admit that the Rosebud Coal seam in Area F is saturated and functions as an aquifer. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ objects to this discovery request on the grounds of relevance. This discovery request seeks information not relevant to the subject matter of this appeal and not reasonably calculated to lead to the discovery of admissible evidence. DEQ has already stated in response to Petitioner's First Set of Discovery Requests, Interrogatory No. 13, that DEQ justified its decision not to include Area F within the CHIA because "[t]he proposed action was determined to have no impacts to mine Area C making it unnecessary to include Area F," and cited to those specific portions of the CHIA that support its conclusion (See DEQ's Answer to Interrogatory No. 13). Without waiving its objections, DEQ admits that the Rosebud coal seam

Exhibit 16

in Area F varies from completely unsaturated to completely saturated. Based on the definition of "aquifer" contained in § 82-4-203(5), MCA, the Rosebud coal seam would be considered an aquifer in some parts of Area F and not an aquifer in other parts of Area F.

REQUEST FOR ADMISSION NO. 46: You are requested to admit that ground water in the Rosebud Coal aquifer generally flows from the west towards the east. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: Admit in part, deny in part. For those portions of the Rosebud Coal seam that meet the definition of "aquifer" contained in § 82-4-203(5), MCA, flow directions vary from location to location. However, DEQ admits that in general groundwater in the Rosebud Coal seam flows in an easterly direction. (See CHIA page 8-7: "Lateral up gradient flow of saturated Rosebud coal is generally from the west at the Rosebud Mine…").

REQUEST FOR ADMISSION NO. 47: You are requested to admit that portions of the Rosebud Coal seam in Area F are up gradient of portions of the Rosebud Coal seam or the spoils aquifers in Area B. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: Deny. As described in the CHIA, page 8-6 "A sizeable stock pond is coincident with the groundwater mound between the west end of Rosebud Mine Area B and south part of Area C." This groundwater mound just west of Area B forms a groundwater divide which separates groundwater in Area B from groundwater in Area F. No groundwater from Area F is predicted to flow to or through Area B.

REQUEST FOR ADMISSION NO. 48: You are requested to admit that there is a hydrologic connection between portions of the Rosebud Coal seam in Area F and downgradient

Exhibit 16

portions of the Rosebud Coal seam or spoils in Area B. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: Deny. See Answer to RFA No. 47. Area B is not downgradient from Area F.

REQUEST FOR ADMISSION NO. 49: You are requested to admit that proposed mining operations in Area F may affect the quantity or quality of surface water or groundwater in downgradient areas of the Rosebud Coal seam or spoils. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ objects to this discovery request as unreasonably duplicative of the information requested in RFA No. 44. DEQ further objects to this discovery request as it is argumentative to the extent that it requires the assumption that the deficiencies identified by DEQ in WECo's Area F application will be resolved and that Area F operations will proceed as proposed. DEQ further objects to this discovery request on the grounds of relevance. This discovery request seeks information not relevant to the subject matter of this appeal and not reasonably calculated to lead to the discovery of admissible evidence. DEQ has already stated in response to Petitioner's First Set of Discovery Requests, Interrogatory No. 13, that DEQ justified its decision not to include Area F within the CHIA because "[t]he proposed action was determined to have no impacts to mine Area C making it unnecessary to include Area F," and cited to those specific portions of the CHIA that support its conclusion (See DEQ's Answer to Interrogatory No. 13). Additionally, as indicated in DEQ's ANSWER to RFA 47-48, Area B is not downgradient from Area F and there is no hydrologic connection between Area B and Area F. Without waiving its objections, DEQ admits that if operations in Area F are approved and proceed as proposed, they may affect the quantity or quality of surface water or groundwater in downgradient areas of the Rosebud Coal seam or spoils, but consideration of these impacts were

not relevant to preparation of the CHIA for Amendment AM4 because Area B is not downgradient from Area F. (See DEQ's Answers to RFA Nos. 44, 47 and 48).

REQUEST FOR ADMISSION NO. 50: You are requested to admit that proposed mining operations in Area F may affect the quantity or quality of water in downgradient areas of the Rosebud Coal seam or spoils in Area B. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ respectfully refers to and reiterates its objections and answer to RFA No. 49.

REQUEST FOR ADMISSION NO. 51: You are requested to admit the Rosebud Coal seam aquifer contributes recharge to the alluvium of East Fork Armells Creek. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ admits that the portion of the Rosebud Coal seam that comes in contact with the alluvium of East Fork Armells Creek (EFAC) is an aquifer and contributes recharge to the alluvium of EFAC.

REQUEST FOR ADMISSION NO. 52: You are requested to admit that the proposed mining operations in Area F may affect recharge of portions of the alluvium of East Fork Armells Creek. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ objects to this discovery request as argumentative to the extent that it requires the assumption that the deficiencies identified by DEQ in WECo's Area F application will be resolved and that Area F operations will proceed as proposed. DEQ further objects to this discovery request on the grounds of relevance. This discovery request seeks information not relevant to the subject matter of this appeal and not reasonably calculated to lead to the discovery

Exhibit 16

of admissible evidence. DEQ has already stated in response to Petitioner's First Set of Discovery Requests, Interrogatory No. 13, that DEQ justified its decision not to include Area F within the CHIA because "[t]he proposed action was determined to have no impacts to mine Area C making it unnecessary to include Area F," and cited to those specific portions of the CHIA that support its conclusion (See DEQ's Answer to Interrogatory No. 13). Without waiving its objections, DEQ answers this request as follows: Even if WECo's Area F permit application is approved and operations proceed in Area F as proposed, DEQ denies that the proposed mining operations in Area F may affect recharge of portions of the alluvium of EFAC. As indicated in DEQ's Answers to RFA Nos. 47-50, the groundwater mound described in DEQ's Answer to RFA No. 47 forms a groundwater divide between Area F and EFAC. Area B and EFAC are not downgradient from Area F. Accordingly, no groundwater from Area F is predicted to flow to or through EFAC alluvium.

REQUEST FOR ADMISSION NO. 53: You are requested to admit that proposed mining operations in Area F may affect recovery of ground water levels in the Rosebud Coal spoils downgradient of mining operations. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ objects to this discovery request as vague and ambiguous. There are no Rosebud Coal spoils. DEQ also respectfully refers to and reiterates its answers to RFA Nos. 47-50 and 52. Without waiving its objections, DEQ answers this request as follows: If WECo's Area F permit application is approved and operations proceed in Area F as proposed, DEQ admits that the proposed mining operations in Area F may affect groundwater levels in the Rosebud Coal seam and spoils downgradient of the proposed mining operations in Area F. The Area F Permit application Appendix O – PHC, Section 3.2.1, page 16 states that "[b]ased on the

results of the groundwater model, the drawdown (Rosebud and McKay coal) within a one mile radius of the Area F permit boundary is predicted to be less than five feet during the mine phase." (See Area F Permit Application, Appendix O, p. 16 and Appendix I-B, Figure I-7). However DEQ denies that Area B and EFAC are downgradient of the proposed mining operations in Area F.

REQUEST FOR ADMISSION NO. 54: You are requested to admit that proposed mining operations in Area F may affect recovery of ground water levels in the Rosebud Coal spoils in portions of Area B. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ respectfully refers to and reiterates its objections and answer to RFA No. 53. Without waiving its objections, DEQ answers this request as follows: For the reasons stated in DEQ's answer to RFA No. 53, DEQ denies this request.

REQUEST FOR ADMISSION NO. 55: You are requested to admit that removal of downgradient portions of the Rosebud Coal seam will decrease the buffering capacity of the coal seam on water quality as spoils water moves down gradient. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ objects to this discovery request on the grounds that it is vague, ambiguous and unintelligible. Accordingly, DEQ cannot truthfully admit or deny the request.

REQUEST FOR ADMISSION NO. 56: You are requested to admit that removal of coal in Area B will decrease the buffering capacity of the coal seam on water quality as spoil water from up gradient portions of the mine moves downgradient. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ respectfully refers to and reiterates its objections and answer to RFA No. 55.

REQUEST FOR ADMISSION NO. 57: You are requested to admit that removal of coal in Area B may decrease the buffering capacity of the coal seam on water quality as spoil water from Area F moves downgradient. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ respectfully refers to and reiterates its objections and answer to RFA Nos. 55-56.

INTERROGATORY NO. 32: Please state whether mining operations in Area F may have any impact on water quality or water quantity on surface or groundwater, including potential impacts to recovery of ground water levels, in any portion of Area B. If you answer is anything other than an unqualified "Yes," please set for in detail and with specificity the basis for your answer and any facts that support your answer.

ANSWER: DEQ objects to this discovery request on the grounds that is compound and that Petitioner has already propounded the maximum number of 50 interrogatories, including subparts, allowed under Rule 33, Mont. R. Civ. P. DEQ respectfully refers to and reiterates its objections and answers to RFA Nos. 47-50. Without waiving its objections, DEQ answers this request as follows: If WECo's Area F permit application is approved and operations proceed in Area F as proposed, DEQ denies that may have any impact on water quality or water quantity on surface or groundwater, including potential impacts to recovery of ground water levels, in any portion of Area B because Area B is not downgradient from Area F. (See DEQ's Answers to RFA Nos. 44, 47 and 48). Additionally, as indicated in DEQ's answer to RFA No. 53, any drawdown from Area F is not expected to reach Area B.

Exhibit 16

REQUEST FOR PRODUCTION NO. 13:

Please produce any and all documents, including emails, computer files, or hand written notes, related to the phone conversation between WECO staff, DEQ staff, including Chris Yde, and consultant Michael Nicklin, that occurred on Tuesday, April 30, 2013.

ANSWER: DEQ objects to this discovery request to the extent that it seeks to discover privileged information. Without waiving its objections, DEQ does not have a record of a phone conversation occurring between WECO staff and DEQ staff , including Chris Yde, and consultant Michael Nicklin, on Tuesday April 30, 2013 related to the Rosebud Mine. However, DEQ does have a record of a conference call that took place between WECO staff and DEQ staff, including Chris Yde, and consultant Michael Nicklin, on May 16, 2013, to discuss the Area B PHC. Notes from this conference call taken by Chris Yde, and a summary of discussion points submitted by Michael Nicklin prior to the call are attached hereto as Exhibits 44-45, respectively.

REQUEST FOR PRODUCTION NO. 14: Please produce any maps or figures in DEQ's possession or control that depict the potentiometric surface or potentiometric head in the Rosebud coal seam and/or spoil that include Area F.

ANSWER: DEQ objects to this discovery request as overly broad and burdensome, as the requested documents are publicly available online, and as such, can be obtained by Petitioners with no more burden than DEQ. DEQ further objects to this discovery request on the grounds of relevance. Without waiving its objections, DEQ answers this discovery request as follows: DEQ and WECO have already produced responsive, non-privileged documents which are contained within WECO's Area F application PHC Report in their production of documents, and these documents, including the relevant maps and figures are also publically available online. (See Area F Application, Appendix I-A, Plate GM-B1; Figure GM-13; Figure GM-17, page 2 and

Area B AM4 CHIA Figure 8-5 (includes eastern half of Area F)), attached hereto as Exhibits 46-49, respectively.

REQUEST FOR PRODUCTION NO. 15: Please produce any probable hydrologic consequences reports or determinations or ground water models in DEQ's possession or control for proposed mining operations in Area F.

ANSWER: DEQ respectfully refers to and reiterates its objections and answer to RFP No. 14, and asserts that PHC reports, determinations or ground water models for proposed Area F mining operations are not relevant to the Area B AM4 CHIA . Without waiving its objections, DEQ answers this discovery request as follows: DEQ and WECo have already produced responsive, non-privileged documents which are contained within WECo's Area F application PHC Report (Appendix O) The requested groundwater models are included in the Area F application as Appendix I-A and I-B. These documents are also publically available online.

REQUEST FOR PRODUCTION NO. 16: Please produce any and all documents in DEQ' s possession or control in which DEQ employees state, determine, or explain that analysis of impacts from operations of Area F did not have to be considered in the CHIA.

ANSWER: None Exist.

INTERROGATORY NO. 33: If you contend that the CHIA adequately assessed whether the cumulative hydrologic impacts of mining and reclamation activities within the cumulative hydrologic impact area would cause violation of electrical conductivity standards in Spring Creek, Pony Creek, Cow Creek, South Fork Cow Creek, Emilee Coulee, or Lee Coulee, please describe and explain in detail every fact or expert opinion that supports your contention.

ANSWER: DEQ objects to this discovery request on the grounds that is compound and that Petitioner has already propounded the maximum number of 50 interrogatories, including

subparts, allowed under Rule 33, Mont. R. Civ. P. DEQ further objects to this discovery request as overly burdensome and oppressive to the extent that it requires DEQ to describe and explain in detail each fact set forth in the CHIA that it relied on in making this assessment. DEQ further objects to this discovery request to the extent that it seeks premature disclosure of expert opinions. DEQ has not decided on which, if any expert witnesses may be called during a hearing in this matter. DEQ reserves the right to identify experts and to disclose expert opinions in accordance with any scheduling order. Without waving its objections, DEQ answers this discovery request as follows: The CHIA documented that the numeric EC standards for tributaries of Rosebud Creek were one of the criteria used to evaluate impacts to surface waters (On page 2-4 the CHIA states "[s]tandards for electrical conductivity (EC) and sodium adsorption ratio (SAR) set forth by ARM 17.30.670(4) apply to tributaries of Rosebud Creek."). Additionally, the CHIA concluded for each of the drainages listed that the proposed action in Area B would have no impacts (On page 9-6 the CHIA states "[t]he proposed action will not affect the Cow Creek drainage basin." On page 9-13 the CHIA states "[t]he proposed expansion of mining in Rosebud Area B in AM 4 will not affect the water quality in the Lee Coulee drainage. Spoil water from Area B AM 4 cuts will not contribute to surface flow." On page 9-14 the CHIA states "because the proposed mining in AM4 will not contribute water to Miller Coulee, the proposed action is designed to prevent material damage." Also on page 9-14 the CHIA states "The proposed mining in AM4 will not contribute water to Pony Creek, therefore the proposed action is designed to prevent material damage." On page 9-16 the CHIA states "[t]he proposed mining with AM4 will not affect the Spring Creek drainage, and therefore the proposed action is designed to prevent material damage."). It is reasonable to conclude that if there are no impacts the EC standard will not be violated.

Exhibit 16

REQUEST FOR ADMISSION NO. 58: You are requested to admit that there are wadeable streams within the cumulative hydrologic impact area identified in the CHIA. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ admits that Rosebud Creek is a wadeable stream within the CIA identified in the CHIA, and that there are additional stream reaches that are wadeable, but not entire streams other than Rosebud Creek.

INTERROGATORY NO. 34: Please identify any and all streams or stream segments within in the cumulative hydrologic impact area that are wadeable.

ANSWER: DEQ objects to this discovery request on the grounds that is compound and that Petitioner has already propounded the maximum number of 50 interrogatories, including subparts, allowed under Rule 33, Mont. R. Civ. P. DEQ further objects to this discovery request as overly burdensome and oppressive to the extent that it requires DEQ to compile a list or summarize information provided in the CHIA. Without waving its objections, DEQ answers this discovery request as follows: West Fork Armells Creek, Stocker Creek, East Fork Armells Creek, unnamed tributaries of East Fork Armells Creek, Spring Creek, Cow Creek, Hay Coulee, Emile Coulee, Lee Coulee, and Rosebud Creek may contain perennial or intermittent reaches which are wadeable streams. Only Rosebud Creek is wadeable for its entire reach. The remaining streams listed are mostly non-wadeable, with short intermittent/perennial reaches that are wadeable.

REQUEST FOR ADMISSION NO. 59: You are requested to admit that East Fork Armells Creek upstream of Colstrip is impaired and not meeting water quality standards. If your

Exhibit 16

answer is anything other than an unqualified admission, please state specifically and in detail the basis for your answer.

ANSWER: DEQ admits that DEQ's 2014 Water Quality Standards Attainment Record for East Fork Armells Creek (segment MT42K002_170) lists 'Aquatic Life' as impaired due to 'alteration in stream-side or littoral vegetative covers' with 'Surface Mining' listed as an unconfirmed source. However, the aquatic life impairment information contained in the 2014 Water Quality Standards Attainment Record was derived from a 2006 DEQ impairment determination that was based on erroneous information. The conclusion that aquatic life was impaired in 2006 was based upon evidence of habitat impairment that was incorrect. No aquatic life survey was done at that time to support the aquatic life impairment determination. Since the 2006 assessment there has been extensive data collected, including aquatic life surveys for EFAC, which can be used to conduct an updated aquatic life use support determination.

INTERROGATORY NO. 35:

A. Please identify each person from DEQ who, in development of the CHIA, reviewed the Memorandum from Penny Hunter and Jason Vogel of Arcadis U.S. Inc. to WECo, dated December 14, 2014.

B. For each person identified in part A., please identify the professional qualifications of that person.

ANSWER: DEQ objects to this discovery request on the grounds that it contains multiple subparts and that Petitioner has already propounded the maximum number of 50 interrogatories, including subparts, allowed under Rule 33, Mont. R. Civ. P. DEQ further objects to this discovery request on the grounds of relevance. This discovery request seeks information not relevant to the subject matter of this appeal and not reasonably calculated to lead to the discovery

Exhibit 16

of admissible evidence. DEQ further objects to this discovery request to the extent that it seeks premature disclosure of expert identities, qualifications, and opinions. DEQ has not decided on which, if any expert witnesses may be called during a hearing in this matter. DEQ reserves the right to identify experts and to disclose expert opinions in accordance with any scheduling order. Without waving its objections, DEQ answers this discovery request as follows:

A. DEQ cannot be reasonably expected to know all of the individuals at DEQ that may have reviewed the Memorandum from Penny Hunter and Jason Vogel of Arcadis U.S. Inc. to WECo, dated December 14, 2014. To the best of DEQ's knowledge, the following DEQ staff may have reviewed the memorandum: Emily Hinz, Angela McDannel and Pete Schade.

B. DEQ will disclose the professional qualifications of expert witnesses identified in this matter in accordance with the scheduling order.

REQUEST FOR ADMISSION NO. 60: You are requested to admit that DEQ representatives from WECo met with staff from DEQ on or about September 13, 2015, regarding results from an aquatic life survey of East Fork Armells Creek. If you answer is anything other than an unqualified admission, state in detail the basis for your answer.

ANSWER: Deny. DEQ has no record of any such meeting occurring on or about September 13, 2015, which was a Sunday. DEQ admits that there is a record that a meeting apparently occurred on or about September 21, 2015.

REQUEST FOR PRODUCTION NO. 17: Please produce any and all documents in DEQ's possession or control, including but not limited to electronic documents, hand-written notes, emails, meeting agendas, and meeting summaries, related to the meeting between DEQ personnel and personnel or representatives of WECo on September 13, 2015.

Exhibit 16

ANSWER: See the email from Dicki Peterson to Chris Yde, forwarded to Emily Hinz, Melissa Sjolund, and Pete Schade dated September 23, 2015, regarding "Aquatic life presentation", attached hereto as Exhibit 50.

REQUEST FOR ADMISSION NO. 61: You are requested to admit that the summary presented to DEQ by Penny Hunter on or about September 13 of the survey of aquatic life in East Fork Armells Creek conducted by Arcadis in 2014 stated that East Fork Armells Creek did not meet aquatic life criteria. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ objects to this discovery request on the grounds of relevance. This discovery request seeks information not relevant to the subject matter of this appeal and not reasonably calculated to lead to the discovery of admissible evidence. Without waving its objections, DEQ answers this discovery request as follows: DEQ admits that Penny Hunter's presentation stated as follows:

"Conclusions and Recommendations

The large amount of variability inherent within ephemeral systems, and the low quality of habitat and benthic communities, would not provide a strong indicator of water quality impacts due to mining activity.

- Flow and natural levels of organic matter are more likely to drive aquatic community dynamic than other factors

Although EFAC supports aquatic life, aquatic life criteria are not met.

- Baseline conditions are a better indicator of existing use
- Criteria are based on different organisms not present in EFAC

Aquatic life monitoring will likely demonstrate natural variability; unlikely to demonstrate impacts from mining"

However, Penney Hunter's conclusion that "aquatic life criteria are not met" is based on data from the 1970s and therefore is not relevant to today's conditions. In order to determine whether aquatic life criteria are currently met, DEQ should conduct an evaluation using the most recent data as well as the most recent methodologies for evaluating this data.

REQUEST FOR ADMISSION NO. 62: You are requested to admit that operations of the Rosebud Mine are contributing to the impairment of East Fork Armells Creek. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ objects to this discovery request as vague and ambiguous. DEQ further objects to this discovery request as unreasonably duplicative of the information requested in RFA No. 24. Without waving its objections, DEQ respectfully refers to and reiterates its answer to RFA No. 24.

INTERROGATORY NO. 36: Your response to INTERROGATORY NO. 28(B) states that "concerns were raised that potential inputs of additional salinity, sulfate, and chloride to EFAC from the Rosebud Mine may cause material damage to the protected beneficial use of aquatic life support for C-3 waters." Please state whether DEQ employees believed that these pollutants were contemporaneously causing material damage in East Fork Armells Creek.

ANSWER: DEQ objects to this discovery request on the grounds that Petitioner has already propounded the maximum number of 50 interrogatories, including subparts, allowed under Rule 33, Mont. R. Civ. P. Without waving its objections, DEQ answers this discovery request as follows: Any concerns that were identified in DEQ's answer to INTERROGATORY NO. 28(A)-(C) were adequately addressed by WECo, and DEQ ultimately concluded, as stated in the CHIA, that there would be no material damage to EFAC as a result of the Area B AM4 mining operations.

Exhibit 16

REQUEST FOR ADMISSION NO. 63: You are requested to admit that the beneficial use of aquatic life support in East Fork Armells Creek may be impaired even if some aquatic life can be detected in the water body. If you answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ objects to this discovery request to the extent that it calls for a legal conclusion, requires speculation, and is irrelevant. This discovery request seeks information not relevant to the subject matter of this appeal and not reasonably calculated to lead to the discovery of admissible evidence. Additionally, DEQ is without sufficient knowledge or information to affirmatively admit or deny the request as the request calls for a speculative admission or a hypothetical question. Without waving its objections, DEQ answers this discovery request as follows: Aquatic Life Beneficial-Use determinations are based on data and information collected for that specific purpose, and are conducted by the Water Quality Monitoring Section of the DEQ's Water Quality Bureau. How aquatic life assemblages are used in making Beneficial Use determinations are documented in the Water Quality Monitoring Section's SOPs and Methodologies.

INTERROGATORY NO. 37: Please summarize the meeting between John North and Dana David and John Martin representing WECo in May 2014 regarding the Rosebud Mine.

ANSWER: DEQ objects to this discovery request on the grounds that Petitioner has already propounded the maximum number of 50 interrogatories, including subparts, allowed under Rule 33, Mont. R. Civ. P. DEQ further objects to this discovery request to the extent that it seeks to discover privileged information and/or the mental impressions and/or legal strategies of counsel for DEQ and WECo. Without waiving its objections, DEQ has no recollection of any meeting occurring between counsel for DEQ and counsel for WECo in May 2014.

REQUEST FOR ADMISSION NO. 64: You are requested to admit that in their May 2014 meeting with John Martin, John North and Dana David raised concerns about material damage occurring to East Fork Armells Creek from sulfate, salinity, and chloride from the Rosebud Mine. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ respectfully refers to and reiterates its objections and answer to INT No. 37. Without waving its objections, DEQ denies that a meeting occurring between counsel for DEQ and counsel for WECo in May 2014.

REQUEST FOR PRODUCTION NO. 18: Please produce any documents, including but not limited to memos, handwritten notes, or emails, in your possession or control that summarize the May 2014 meeting between John North and Dana David of DEQ and John Martin representing WECo.

ANSWER: DEQ respectfully refers to and reiterates its objections and answers to INT No. 37 and RFA No. 64. Without waving its objections, DEQ responds to this discovery request as follows: None exist.

INTERROGATORY NO. 38: Please identify any mitigation measures that DEQ requested or required WECo to undertake to address concerns about material damage from sulfate, chloride, or salinity in East Fork Armells Creek.

ANSWER: DEQ objects to this discovery request on the grounds that Petitioner has already propounded the maximum number of 50 interrogatories, including subparts, allowed under Rule 33, Mont. R. Civ. P. Without waving its objections, in a Deficiency letter "AM4, Seventh Round Acceptability Deficiency" dated June 3, 2014, DEQ requested additional information from WECo, including an aquatic life survey, to address any concerns DEQ staff

regarding the potential for material damage to EFAC from sulfate, chloride, or salinity. After DEQ reviewed the additional information provided by WECo in the ABC PHC Addendum to Appendix M of the Area B AM4 permit application, no mitigation was required as no material damage was indicated, as described in the CHIA. However, the Written Findings for the amended permit (Amendment AM4) contains stipulations for continued aquatic life monitoring in all intermittent reaches.

REQUEST FOR PRODUCTION NO. 19: Please produce any and all documents that describe the process or procedure by which DEQ determines whether a waterbody meets applicable water quality standards.

ANSWER: DEQ objects to this discovery request on the grounds that it is overly broad and burdensome and the documents requested are publicly available online, and as such, can be obtained by Petitioners with no more burden than DEQ. DEQ further objects to this discovery request on the grounds of relevance. This discovery request seeks information not relevant to the subject matter of this appeal and not reasonably calculated to lead to the discovery of admissible evidence, as the Coal Section evaluates whether mining operations are causing violations of WQ standards, but does not conduct waterbody standards or beneficial use evaluations. These determinations are made by another division within DEQ. Without waving its objections, DEQ responds to this discovery request as follows: The Water Quality Monitoring Section of the DEQ's Water Quality Bureau routinely conducts assessments of Montana's streams and evaluates data to determine whether streams are meeting their beneficial uses and reports this information every two years to the EPA in Montana's Water Quality Integrated Report. See http://deq.mt.gov/Water/WQPB/cwaic . Assessment methodologies used to determine whether a waterbody meets applicable water quality standards consist of a variety of SOPs and

methodology guidance developed by the DEQ specifically for this purpose. Relevant documents can be found at http://deq.mt.gov/Water/WQPB/qaprogram/sops and include (hyperlinks below):

- WQPBWQM-001 - Water Quality Assessment Method
- Nutrient Assessment Method
- Metals Assessment Method
- Sediment Assessment Method
- Historic Water Quality Assessment Method (2000-2008).

As indicated above, these documents may be downloaded by Petitioners directly from DEQ's website.

REQUEST FOR PRODUCTION NO. 20: Please produce any and all documents in DEQ's possession or control regarding communications between DEQ personnel and WECo personnel or representatives that discuss or address DEQ's concerns about material damage in East Fork Armells Creek due to salinity, sulfates, or chloride.

ANSWER: DEQ objects to this discovery request to the extent that it seeks to discover privileged information. Without waiving its objections, DEQ has already produced responsive, non-privileged documents in response to Petitioner's First Set of Discovery Requests.

REQUEST FOR ADMISSION NO. 65: You are requested to admit that DEQ's CHIA does not consider future impacts of all mining operations on water quality in Rosebud Creek. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ denies that the CHIA does not consider future impacts of all mining operations on water quality in Rosebud Creek. DEQ considered the entire area within which impacts to the hydrologic balance resulting from the proposed operation may interact with the impacts of all previous, existing and anticipated mining in the Rosebud Creek drainage on surface and ground water systems.

REQUEST FOR ADMISSION NO. 66: You are requested to admit that the evidence before DEQ at the time it issued its CHIA did not affirmatively demonstrate that the cumulative hydrologic impacts of all mining operations in Lee Coulee, Miller Coulee, Cow Creek, Pony Creek, Hay Coulee, and Spring Creek will not contribute to Rosebud Creek's gaining of salts downstream of Lee Coulee. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ objects to this discovery request as argumentative to the extent that it requires the assumption that the law requires WECO's application to affirmatively demonstrate that the cumulative hydrologic impacts of all mining operations will not contribute to Rosebud Creek's gaining of salts downstream of Lee Coulee. DEQ further objects to this discovery request on the grounds of relevance. This discovery request seeks information not relevant to the subject matter of this appeal and not reasonably calculated to lead to the discovery of admissible evidence. DEQ further objects to this discovery request to the extent it requires DEQ to characterize the CHIA, a document which speaks for itself. Without waiving its objections, DEQ denies that it is required to affirmatively demonstrate that the cumulative hydrologic impacts of all mining operations . . . will not contribute to Rosebud Creek's gaining of salts downstream of Lee Coulee. Pursuant to § 82-4-227(3)(a), WECo is required to affirmatively demonstrate through its permit application, that "the assessment of the probable cumulative impact of all anticipated mining in the area on the hydrologic balance has been made by the department and the proposed operation of the mining operation has been designed to prevent material damage to the hydrologic balance outside the permit area;" WECo's application affirmatively demonstrates and DEQ's CHIA confirms that the proposed operation is designed to prevent material damage to Rosebud Creek.

Exhibit 16

REQUEST FOR ADMISSION NO. 67: You are requested to admit that the evidence before DEQ at the time it issued its CHIA did not affirmatively demonstrate that the cumulative hydrologic impacts of all mining operations in Lee Coulee, Miller Coulee, Cow Creek, Pony Creek, Hay Coulee, and Spring Creek will not contribute to exceedances of water quality standards for specific conductance in Rosebud Creek downstream of Lee Coulee. If your answer is anything other than an unqualified admission, please state in detail the basis for your answer.

ANSWER: DEQ respectfully refers to and reiterates its objections and answer to RFA No. 66. Without waiving its objections, DEQ denies that it is required to affirmatively demonstrate that the cumulative hydrologic impacts of all mining operations . . . will not contribute to exceedances of water quality standards for specific conductance in Rosebud Creek downstream of Lee Coulee. Pursuant to § 82-4-227(3)(a), WECo is required to affirmatively demonstrate through its permit application, that "the assessment of the probable cumulative impact of all anticipated mining in the area on the hydrologic balance has been made by the department and the proposed operation of the mining operation has been designed to prevent material damage to the hydrologic balance outside the permit area;" WECO's application affirmatively demonstrates and DEQ's CHIA confirms that the proposed operation is designed to prevent material damage to Rosebud Creek.

INTERROGATORY NO. 39: If you contend that there is a hydrological connection between clinker deposits in the area between Area B of the Rosebud Mine and the Big Sky Mine and the Rosebud coal seam, please describe and explain in detail every fact or expert opinion that supports your contention.

ANSWER: DEQ objects to this discovery request on the grounds that is compound and that Petitioner has already propounded the maximum number of 50 interrogatories, including

subparts, allowed under Rule 33, Mont. R. Civ. P. DEQ further objects to this discovery request as overly burdensome and oppressive to the extent that it requires DEQ to describe and explain in detail each fact set forth in the CHIA that it relied on in making this assessment. DEQ further objects to this discovery request to the extent that it seeks premature disclosure of expert opinions. DEQ has not decided on which, if any expert witnesses may be called during a hearing in this matter. DEQ reserves the right to identify experts and to disclose expert opinions in accordance with the scheduling order. Without waiving its objections, DEQ refers Petitioners to the following relevant sections of the CHIA: Page 8-6 "An apparent recharge area also is visible in the higher elevations at the northeast part of Big Sky Mine Area A...." "Fractured clinker permits greater infiltration of precipitation and surface flow and locally may be a source of recharge. "Page 8-11 "As in all of the shallow, local bedrock aquifers, the main source of recharge originates from uplands west of active mining in the Rosebud Mine and north of mining in Big Sky Mine...." Page 9-59 "Due to a large deposit of clinker throughout much of the area between the two mines, enhanced aquifer recharge will serve to dilute spoil water quality impacts in this area."

INTERROGATORY NO. 40: Please identify every document that DEQ considered in preparing its CHIA that provides evidence of a hydrological connection between clinker deposits in the area between Area B of the Rosebud Mine and the Big Sky mine and the Rosebud coal seam.

ANSWER: DEQ objects to this discovery request on the grounds that Petitioner has already propounded the maximum number of 50 interrogatories, including subparts, allowed under Rule 33, Mont. R. Civ. P. Without waiving its objections, DEQ refers Petitioners to the PHC and model report in Appendix M of the AM4 permit application.

Exhibit 16

REQUEST FOR PRODUCTION NO. 21: Please produce the documents identified in your answer to INTERROGATORY NO. 42.

ANSWER: DEQ objects to this discovery request as vague, ambiguous, unintelligible and overly burdensome. DEQ has not been asked to identify any documents in response to INTERROGATORY NO. 42, and as such, is not able to provide an answer to this request.

REQUEST FOR PRODUCTION NO. 22:

Please produce the following cumulative hydrologic impact assessments:

A. Rosebud Area D Application 115, November 1985;

B. Rosebud Mine Area A Application 107, June 1984;

C. Rosebud Mine Area B Second Extension, June 1983;

D. Big Sky Mine Area B Application 180, June 2007;

E. Big Sky Mine Area B 1988, New Permit, November 1988;

F. Big Sky Mine Area A Snider's Amendment, April 1987.

ANSWER: DEQ objects to this discovery request on the grounds of relevance. This discovery request seeks information not relevant to the subject matter of this appeal and not reasonably calculated to lead to the discovery of admissible evidence. DEQ further objects to this discovery request on the grounds that it is overly broad and burdensome. Without waving its objections, copies of the requested documents are attached hereto as Exhibits 51-56, respectively.

INTERROGATORY NO. 41: Please identify all documents that DEQ personnel reviewed in preparing the CHIA.

ANSWER: DEQ objects to this discovery request on the grounds that Petitioner has already propounded the maximum number of 50 interrogatories, including subparts, allowed

under Rule 33, Mont. R. Civ. P. Without waiving its objections, DEQ refers Petitioners to all documents cited in the CHIA and all permit application materials for Amendment AM4.

INTERROGATORY NO. 42: Please identify all property owners, including surface and sub-surface owners, of the properties on which impoundments of coal combustion resides are located in and around Colstrip, Montana.

ANSWER: DEQ objects to this discovery request on the grounds that Petitioner has already propounded the maximum number of 50 interrogatories, including subparts, allowed under Rule 33, Mont. R. Civ. P. DEQ further objects to this discovery request on the grounds of relevance. This discovery request seeks information not relevant to the subject matter of this appeal and not reasonably calculated to lead to the discovery of admissible evidence. DEQ further objects to this discovery request on the grounds that it is overly broad and burdensome.

INTERROGATORY NO. 43: Please identify any agreements between WECo and any owners or operators of the Colstrip Generating Station regarding use, placement, or disposal of coal combustion residues at the Rosebud Mine.

ANSWER: DEQ respectfully refers to and reiterates its objections and answer to INTERROGATORY NO. 42. DEQ further objects to this discovery request to the extent that Petitioners seek information not within the possession or control of DEQ, and outside of the personal knowledge of DEQ.

INTERROGATORY NO. 44: Please state whether DEQ has ever approved use, placement, or disposal of coal combustion residue at the Rosebud Mine or the Big Sky Mine. If your answer is anything other than an unqualified "No," please set forth the following information specifically and in detail:

A. Identify all such approvals;

Exhibit 16

B. Describe when, where, and for how long coal combustion residue has been used, placed, or disposed of at the Rosebud or Big Sky Mine.

ANSWER: DEQ objects to this discovery request on the grounds that it is compound and Petitioner has already propounded the maximum number of 50 interrogatories, including subparts, allowed under Rule 33, Mont. R. Civ. P. DEQ further objects to this discovery request on the grounds of relevance. This discovery request seeks information not relevant to the subject matter of this appeal and not reasonably calculated to lead to the discovery of admissible evidence. DEQ further objects to this discovery request on the grounds that it is overly broad, burdensome and intended to create an undue burden on DEQ, as it would require DEQ to compile and summarize information contained in the Rosebud Mine annual reports and applicable permits. Without waving its objections, DEQ has approved the use of bottom ash at the Rosebud Mine "as a tank or culvert bedding material and a road and parking facilities sanding material." DEQ will make applicable Rosebud Mine annual reports and permit documents available for Petitioner's review upon reasonable request.

REQUEST FOR PRODUCTION NO. 23: Please produce any and all documents in DEQ's possession or control that you identified in your answer to INTERROGATORY NO. 43.

ANSWER: DEQ respectfully refers to and reiterates its objections and answer to INTERROGATORY NO. 43. Without waiving its objections, DEQ answers this discovery request as follows: None exist.

INTERROGATORY NO. 45: Please identify when, where, and for how long coal combustion residues have been used, placed, or disposed of at the Rosebud Mine or the Big Sky Mine.

ANSWER: DEQ respectfully refers to and reiterates its objections and answer to INTERROGATORY NO. 44.

INTERROGATORY NO. 46:

A. Please identify each and every conference call or in-person meeting between the persons identified in INTERROGATORY NO. 1, INTERROGATORY NO. 3, or INTERROGATORY NO. 4 and employees or representatives of WECo regarding WECo's application for Amendment AM4;

B. Please state in detail the subject matter of each and every conference call or in-person meeting between persons identified in INTERROGATORY NO. 1, INTERROGATORY NO. 3, or INTERROGATORY NO. 4 and employees or representatives of WECo regarding Wesco's application for Amendment AM4;

C. Please identify every meeting or call agenda or meeting or call summary from each and every conference call or in-person meeting between persons identified in INTERROGATORY NO. 1, INTERROGATORY NO. 3, or INTERROGATORY NO. 4 and employees or representatives of WECO regarding WECo's application for Amendment AM4.

ANSWER: DEQ objects to this discovery request on the grounds that it is compound and Petitioner has already propounded the maximum number of 50 interrogatories, including subparts, allowed under Rule 33, Mont. R. Civ. P. DEQ further objects to this discovery request on the grounds of relevance. This discovery request seeks information not relevant to the subject matter of this appeal and not reasonably calculated to lead to the discovery of admissible evidence. DEQ further objects to this discovery request on the grounds that it is overly broad, burdensome and intended to create an undue burden on DEQ.

REQUEST FOR PRODUCTION NO. 24:

Please produce every document identified in INTERROGATORY NO. 46.C.

ANSWER: DEQ respectfully refers to and reiterates its objections and answer to INTERROGATORY NO. 46.

VERIFICATION FOR INTERROGATORIES AND REQUESTS FOR PRODUCTION

STATE OF MONTANA)

ss.

County of Lewis & Clark)

I, Chris A. Yde, being first duly sworn, state that I am the supervisor of the Coal and Opencut Mining Bureau, Coal Section, Montana Department of Environmental Quality, and I am authorized to answer the foregoing discovery requests and to make this verification. I have read the foregoing Answers to Requests for Admission, Interrogatories and Requests for Production, and the information provided in them is true and correct to the best of my knowledge and belief.

Chris A. Yde

Subscribed and sworn to before me by Chris Yde, this 11th day of April, 2016.

HILLARY HOULE
NOTARY PUBLIC for the
State of Montana
Residing at Helena, Montana
My Commission Expires
May 19, 2019

Signature of Notary

As the attorney for the Department of Environmental Quality, I am signing these Answers to Requests for Admission, Interrogatories, and Requests for Production and certify this response in accordance with M. R. Civ. P. Rule 26(g)(1).

STATE OF MONTANA,
DEPARTMENT OF
ENVIRONMENTAL QUALITY

Rebecca Convery
Special Assistant Attorney General

Exhibit 16

CERTIFICATE OF SERVICE

The undersigned certifies that on April 11, 2016, she caused the original or a copy of the foregoing DEQ Responses to Petitioner's Second Discovery Requests to be delivered or transmitted to the person named below as follows:

Original by first class and copy by electronic mail:

Shiloh Hernandez
Western Environmental Law Center
103 Reeder's Alley
Helena, MT 59601

By:

Exhibit 16

Attachment 1: WECO B Amendment CHIA; Surface Water

Proposed WECO Area B Amendment

Proposed disturbance in Western Energy's Area B Amendment mine plan would lie primarily within the East Fork Armells Creek (EFAC) drainage basin, above Colstrip, with a portion extending over the divide into the Lee Coulee drainage, a tributary of Rosebud Creek (see Map 1). The Area B mine plan amendment would increase surface disturbance by 2102 acres, as a result of extending the pits approximately 4.5 miles to the west.

Combined surface disturbance from the proposed mine plan amendment and the existing Area B permit would total 4878 acres, with east-west pits extending up to 8.5 miles along slopes north of the drainage divide between EFAC and Rosebud Creek. A small portion of total surface disturbance in Area B would occur in upper northwest tributaries of Lee Coulee (214 acres; see Map 1). Here, final pits and highwall reduction would cross south over approximately 1.5 miles of the Rosebud drainage divide into Lee Coulee along the south-central portion of the amendment area (sections 14 and 15, T1N R40E).

Existing and Proposed Mining Disturbance - Colstrip Region

Mining disturbance in the EFAC drainage basin currently totals approximately 8306 acres (WECO mine areas A, B, C, D and E, including ~209 acres prelaw mining; Table 1). The proposed Area B amendment and other permitted life-of-mine plans would increase life-of-mine surface disturbance in the EFAC drainage to about 16,605 acres (25.9 $mi.^2$; see Map 1, Table 2).

Mining disturbance in the Rosebud Creek drainage basin currently totals approximately 5782 acres (WECO mine areas D, E and Pit 6, Big Sky Coal Company (BSCC) mine areas A and B, including ~1076 acres prelaw mining). The Area B amendment and other permitted life-of-mine plans would increase life-of-mine surface disturbance in the Rosebud drainage to about 9371 acres (14.6 $mi.^2$).

Additional mining disturbance has been permitted, but not yet begun, in the upper West Fork Armells Creek (WFAC) drainage basin (WECO Area C; see Map 1). The Area C permit would bring life-of-mine surface disturbance in the WFAC drainage to approximately 1645 acres. Combined life-of-mine disturbance in Armells Creek (both East and West Forks) would total about 18,250 acres (28.5 $mi.^2$). Cumulative life-of-mine disturbance for the entire Colstrip region (both Armells and Rosebud Creek drainages) would total about 27,621 acres (43.2 $mi.^2$).

Because mining operations and reclamation proceed simultaneously, a complex pattern of disturbance conditions occur at any one time during mining, and evolve toward completed reclamation over proposed life-of-mine periods (e.g. WECO B: 20 years, WECO C: 38 years). Principal mining-related surface disturbances include: soil removal, storage and redistribution; active pits, backfilled pits and regraded overburden (incl. boxcut spoils and highwall reduction); revegetation; access and haulroads, facilities, and sediment ponds.

Cumulative Mining Disturbance

Taken alone, life-of-mine operations and reclamation proposed for WECO Area B would disturb about 16% of the 48 $mi.^2$ EFAC drainage basin above Stocker Creek, about 5% of the total 148 $mi.^2$ EFAC drainage, or about 2% of the entire 370 $mi.^2$ Armells Creek drainage (Table 3). Only about 2% of the 20.6 $mi.^2$ Lee Coulee drainage, or less than 0.1% of 799 $mi.^2$ of adjacent Rosebud Creek drainage would be disturbed by proposed WECO Area B mining and reclamation.

Cumulative surface mining operations and reclamation proposed for all Colstrip area mines would disturb nearly 40% of the EFAC drainage basin above Stocker Creek, about 16% of the total EFAC drainage, or about 8% of the entire Armells Creek drainage. With the addition of BSCC's Area B mining, a total of 25% of the Lee Coulee drainage, or less than 1% of the adjacent Rosebud Creek drainage would be disturbed by cumulative surface mining and reclamation proposals.

Surface water systems nearest to mined areas would have the greatest potential for mining-related impacts, both during mining operations and after reclamation. Further downstream, particularly where the disturbed watersheds join larger drainages, measurable and expected impacts would diminish in significance (e.g. lower Armells Creek, Rosebud Creek and Yellowstone River reference sites; see Map 2; Table 3).

Cumulative mining-related impacts to surface water systems in the Colstrip area would potentially be measurable in EFAC below Colstrip to its junction with WFAC. Measurable impacts in WFAC would be limited to the upper portion of the drainage, due to the limited disturbance proposed (see Table 3, Map 2). In the Rosebud Creek drainage, cumulative mining impacts to surface water would potentially be measurable in Lee Coulee, Miller Coulee, and Cow Creek below mining to their junctions with Rosebud Creek. Measurable impacts in other mined tributaries of Rosebud Creek would be limited to the upper portions of those drainages (see Table 3, Map 2).

Operational Impacts of Surface Mining

Operational impacts to offsite surface water systems are related primarily to storage and discharge of storm and snowmelt runoff (and pumped pit water) from runoff and sediment control systems. WECO Sediment ponds are required to retain runoff from storms up to 2.4" (10-year, 24 hour recurrence), and three years of projected sediment loss from disturbed drainages above them. Pond design requirements result in at least temporary interception of all but the larger storm or snowmelt runoff events. In practice, snowmelt runoff (usually in February or March) and successive spring storms (heaviest from April through June) result in more frequent pond discharges. Periodic use of some ponds for storage and discharge of pumped pit water, and as water sources for haulroad dust suppression complicates any general pattern of pond operations.

Seepage losses and surface discharges of stored runoff or pit water from perimeter sediment ponds can affect flows in downgradient alluvial aquifers and streams. The effects of individual sediment ponds would generally be limited to adjacent streams and their alluvial aquifers, unless pond contributions are significant relative to those of the receiving channel or aquifer. For example, an intermittent flow reach has been created in an ephemeral reach of Lee Coulee below BSCC's pond B-9, which has discharged nearly continuously from 11/89 to 11/91, and from 4/93 to 10/94.

Sediment pond discharge samples usually meet MPDES effluent limitations (regulated by Montana Dept. of Health and Environmental Sciences). Most of the local MPDES exceedances are of total suspended solids limits: 35 mg/L (30-day avg.), or 70 mg/L (daily max.). Most pond discharges are similar or lower in suspended solids than storm and snowmelt runoff from local undisturbed drainages, which are highly variable (e.g. WECO sites SW-9A, SW-09 and SW-60 north of the amendment area on EFAC; see Figure 1). In pond discharges with large amounts of groundwater (from pit pumping), dissolved solids are usually higher than in ephemeral runoff from local undisturbed drainages, which are often under 100 mg/L TDS (e.g. WECO site SW-60 on EFAC, north of the proposed amendment area; see Figure 2).

The effects of multiple active sediment ponds in a drainage with significant mining activity (like EFAC) are potentially significant, but would depend on several variables, including the number of active ponds, level of mining activity, amount of pit pumping, and the timing and magnitude of storm and

snowmelt runoff. The cumulative effects of WECO sediment ponds on EFAC surface flow and chemistry are further complicated by MPC power plant and municipal water uses within and adjacent to Colstrip (see text below).

Pit dewatering and drawdown of coal, overburden or adjacent alluvial aquifer water levels could reduce or eliminate intermittent streamflow or ponding during mining operations. In EFAC, mining in Area B (and in adjacent WECO mines) could temporarily dewater alluvial (or other) aquifers contributing baseflow to any connected intermittent flow reaches (e.g. described above) or stockponds (e.g. ponds PO-929 and PO-937). In Lee Coulee, both WECO Area B and BSCC Area B mining would similarly dewater intermittent flowing and ponded reaches during mining operations; drawdowns have already occurred in the Lee Coulee wet reach adjacent to BSCC Area B. Mining-induced dewatering of stream baseflow should taper-off as pits move farther away from the affected stream reach, and backfilled spoil material saturates. However, in Lee Coulee where BSCC has proposed to mine through the intermittent stream reach, special mitigations would be required to reconnect upgradient recharge to approximate premining streamflow conditions.

Postmining Impacts of WECO Area B Mining

Postmining impacts to surface water systems in Area B would depend primarily on reclamation success in approximating premine topography, drainage geomorphology, and distribution of soil, water, and vegetation resources. Vegetative cover data from reclaimed fields in Area B give some evidence of potential recovery of premining hydrologic conditions (see Table 4). Sampling of nine reclaimed fields in Area B show total vegetative cover ranging from 63 to 99% (average 77%; 1993 data). Area B revegetation began in 1977 and continued through 1987; mining disturbance has not advanced since 1986. The youngest revegetated fields in Area B were 6-7 years old in 1993, the oldest 16-17 years; a total of 719 acres has been revegetated (of 1951 acres disturbed).

Topography/Geomorphology

Area B mining and reclamation would result in reclaimed topography that approximates premine topography with a simplified reconfiguration of principal drainage divides, channels, and slopes. The more highly dissected landforms (e.g. upper tributaries and ridgeline areas) would be regraded to a more uniform postmine topography with reduced drainage densities and slope diversity than before mining (see Maps 3 and 4). There would be no disturbance of the EFAC channel immediately north of Area B disturbance limits, but there would be some disturbance of adjacent alluvial terraces.

Because most Area B tributaries would remain undisturbed in at least some portion of their upper and lower reaches, blending of reclaimed and undisturbed topography along upper and lower disturbance limits would tend to result in average slopes being roughly similar between premine and postmine topography (see Maps 3 and 4). However, steeper premine slopes in Area B (e.g. 50-70% with some steeper outcrops) would be much flatter in reclaimed topography (approximately 20-30%). This flattening of steeper features is typical for mined land reclamation, and is due in part to regulatory limits, except in areas where steeper postmine features (e.g. bluff extensions, thin breaks) are allowed. No steeper features are proposed for Area B. Reclaimed topography proposed for the flatter, low elevation areas in Area B would be similar or a little steeper than the premine areas (1-2% slopes).

Some repositioning of channels and drainage boundaries would occur in EFAC and Lee Coulee tributaries within Area B due to displacement of backfilled overburden, regrading and final highwall reduction. Changes in drainage area would be most significant in WECO drainages 021-1, 020, 026, 011, 139, 012 and 127 (see Figure 4, Maps 3 and 4). Adjacent premine drainages 021-1 (781 acres) and 020 (501 acres) would be reconfigured into much larger (1226 acres)

and smaller (58 acres) postmine tributaries, respectively. The reverse would be true for adjacent premine drainages 026 (403 acres) and 139 (57 acres) which would be reconfigured into two more similarly sized drainages (202 and 289 acres, respectively). The change in adjacent drainages would result in much larger peakflows in the lower reach of postmine drainage 021-1, which would be somewhat offset by runoff storage in proposed permanent pond PO-21B. Where proposed changes to premine drainage area and potential runoff are more significant, some channel adjustments could be expected in undisturbed lower reaches of mined drainages, with at least short-term instabilities.

Surface Water Resources

Annual precipitation in the Colstrip area has ranged from 5.84 inches (1979) to 22.12 inches (1978) for the 1948 to 1992 period; the annual average for the period was 14.51 inches (see Figure 3; NCDC 1993). Average monthly precipitation in Colstrip ranges from a low of 0.52 inches (February) to 2.63 inches (June), with the wettest months occurring during spring storms (April through June). Monthly extremes for the period of record have ranged from 0.0 to 9.27 inches (May 1978). Rainfall predominates from May through October, snowfall is common from November to April and contributes approximately one third of the average annual precipitation.

Stream channels in Area B are ephemeral tributaries of EFAC and Lee Coulee with bedrock and structural controls. Most tributary and main channels are incised and vegetated with limited alluvial material in the upper reaches, increasing downchannel. Streamflow in Area B channels generally occurs in response to storm and snowmelt runoff; some limited intermittent flow may also occur in short reaches below springs (see below). Two adjacent intermittent flow reaches have been described in EFAC, beginning near the west end of the amendment area (NW¼ section 17, T1N, R40E) and continuing about two miles downstream to SE¼ section 10 (T1N, R40E). An intermittent/perennial wet reach also occurs in the mainstem Lee Coulee channel within the BSCC Area B permit area. Both of these flowing stream reaches appear to be related to groundwater discharges from adjacent overburden, coal and alluvial aquifers.

Storm runoff in ephemeral channels usually occurs after short intense storms, long duration storms, or after frequent wetting from smaller consecutive rain events. Snowmelt runoff usually occurs in February or March. Runoff duration in ephemeral channels is limited after storms in smaller tributaries, but may persist for weeks during snowmelt periods, especially in larger drainages. The intermittent reaches in EFAC are reported to have baseflow (up to 30 gpm) for much of the year. Intermittent streamflow at a monitoring site in Lee Coulee was common during snowmelt, spring, early summer and fall periods (baseflow up to ~100-200 gpm); individual baseflow periods ranged from over a week to approximately six months in length during the 1985-1993 monitoring period [BSCC flume BRTFL, NE¼ section 25 (near section 30 line; T1N, R40E) in Lee Coulee about two miles below proposed WECO B mining disturbance].

Following backfilling and regrading of mined drainages, runoff from unreclaimed mine spoils above sediment ponds are more flashy than in undisturbed drainages, with higher peakflows and suspended solids concentrations, due to limited infiltration and lack of a vegetative cover. After resoiling and seeding of regraded areas some vegetative stabilization of slopes and channels is initiated, and greater infiltration is promoted. Some rilling and gullying usually occurs as drainage systems stabilize, but this tends to diminish with increasing vegetative cover. Infiltration characteristics are expected to recover gradually toward premining conditions with increased vegetative cover and redevelopment of soil profiles.

Runoff characteristics of reclaimed drainages are expected to approximate those of premining drainages where soil, vegetation and geomorphic conditions are similar. However, because postmine drainages are generally reclaimed to simpler systems with less drainage density, overland flow distances would be somewhat longer, slowing times of runoff concentration, resulting in somewhat

lower runoff peaks of longer duration. These changes in peakflow character would be compounded where postmining slopes are flatter than in premine topography. Water chemistry in stable reclaimed areas is expected to be similar to premining conditions, with variable suspended solids concentrations (depending primarily on runoff magnitude) and low dissolved solids concentrations.

Only two springs have been mapped within the existing and proposed Area B permit boundary (SP-28 and SP-79). SP-28 in WECO drainage 019 has been mined-out, and SP-79 near the upper mining disturbance limit in the upper portion of WECO drainage 129-3 is not proposed to be "removed", but may be temporarily disturbed during mining. Similar, but indirect disturbance may also occur at SP-78, 1000 ft. SSE of SP-79 in a Lee Coulee tributary. Most springs in the area are used primarily by stock and wildlife; limited flow and chemistry data are available (see Table 5).

Five stockponds have been mapped within the existing and proposed Area B permit boundary (PO-911, PO-988, PO-989, PO-990 and PO-129D; see Table 6). Pond PO-911 in WECO drainage 015 was mined-out in 1983, the others would be removed by mining disturbance in the proposed amendment area. WECO proposes to leave five permanent ponds in Area B (see Table 7). Pond PO-21B in WECO drainage 021-1 would be left in the existing Area B; ponds PO-026, PO-129, PO-129B and PO-192B would be left in the proposed amendment area, located in drainages currently holding stock ponds. Stockponds in the area are also used primarily by stock and wildlife, and have limited water level and chemistry data available (see Table 6).

Offsite Disturbances (Non-Mining Activities)

In addition to surface mining disturbance, several important offsite activities also occur in the Colstrip area (see Map 1), including:
- Montana Power Company's power plants, fly ash ponds, and process water ponds (EFAC and Cow Creek);
- Castle Rock Reservoir - a 112-acre surge storage pond for power plant and municipal uses (pumped from the Yellowstone River to an EFAC tributary near Colstrip);
- Colstrip sewage treatment plant discharges and municipal runoff (EFAC);
- roads and railways; and
- the Rosebud County Landfill.

The combined effect of surface mining and Colstrip area offsite disturbances on local hydrology are not fully understood, but some general observations are possible. In addition to effects from upstream mining, changes to the local water balance and chemistry of EFAC are significantly influenced by these offsite disturbances.

Approximately 8000 to 8500 AF/year of Yellowstone River water is pumped via a 29-mile pipeline to the 2250 acre-feet surge storage pond (Castle Rock Reservoir) to supply MPC power plant and Colstrip municipal uses. The MPC power plant complex uses about 7,700 AF/yr (90-95%) of the annual surge pond storage, with 85% of that lost to evaporation through cooling processes and pond surfaces (MDSL/OSM 1983). The remainder of MPC's annual surge pond use is primarily for dust suppression (~400 AF/yr, most lost to evaporation), and seepage to local aquifers (e.g. overburden, coal or spoil aquifers and alluvium in EFAC and Cow Creek).

Total municipal use of surge pond water was estimated at 630 AF/yr (for 1980 population of 3,258). A large part of municipal use was for household and community irrigation, with losses to evapotranspiration, infiltration and urban runoff (MDSL/OSM 1983). Discharge of Colstrip sewage treatment plant effluent totaled 210 AF in 1980, including discharges to EFAC, and adjacent sewage effluent holding ponds (7-23 AF/month; or 130-170 gpm). Recent discharge reports of Colstrip sewage treatment plant effluent are higher,

ranging from 326-393 AF/yr (22-42 AF/month, or 160-340 gpm; 9/89 to 9/94 data (MDHES 1994)).

Seepage from the surge pond northwest of Colstrip to downgradient EFAC alluvium (~1/2 mile) has been estimated at 180 AF/yr (110 gpm; MDSL/OSM 1983). A consistent streamflow increase is apparent between two flume sites located on an adjacent reach of EFAC [between MPC's South flume (AR-2, upstream) adjacent to the sewage effluent holding ponds and North flume (AR-1, downstream) below the surge pond tributary (Hydrometrics 1993)]. Streamflow at MPC's South flume ranged from ~0.2 to 1.2 cfs (~120-520 gpm), while flows at the North flume ranged from ~0.4 to 2.8 cfs (~200-1200 gpm; 1981-1992 data). These increases in baseflow apparently reflect contributions from sewage treatment plant effluent and surge pond seepage. About 6 miles downstream, flow measurements at an EFAC site north of Colstrip ranged from 0 to 169 cfs, exhibiting storm and snowmelt runoff peaks (mean instantaneous flow 3.98 cfs; ~monthly USGS data from 10/74 to 9/85 - see Figure 5).

Water samples from EFAC in the immediate Colstrip area have a wide range of dissolved solids concentrations (e.g. station SW-01: ~1400-7000 mg/L TDS; Figure 2). Yellowstone River water supplied to the surge pond is significantly lower in dissolved solids than EFAC samples (e.g. Yellowstone at Miles City: ~200-600 mg/L TDS, Slagel and others, 1983). MPC's plant process water ponds and effluent holding ponds (fly ash ponds) have very high dissolved solids concentrations (e.g. ranging from about 5,000 to 50,000 mg/L TDS; MPC 1994). However, seepage from ponds at the plant site into EFAC alluvium is estimated to be small compared to alluvial flow above Colstrip (estimated at 340 gpm) and therefore significantly diluted (Hydrometrics 1993). Effluent from Colstrip's sewage treatment plant is apparently lower in dissolved solids than adjacent EFAC water, presumably due to its Yellowstone River source. During a one-day sampling of six EFAC monitoring sites in the Colstrip area, sewage treatment plant effluent measured 1320 mg/L TDS (6/15/93 sample, Hydrometrics 1993). Some dilution of dissolved solids is evident in EFAC below the sewage effluent ponds and the surge pond, due to inflow of lower TDS water.

Conclusions

The proposed amendment to WECO's Area B mine would increase overall mining disturbance in the Colstrip area by 3.6 $mi.^2$, roughly doubling the permitted mining disturbance for Area B.

Proposed Area B amendment disturbance in EFAC (3.3 $mi.^2$) would amount to 18% of total mining disturbance proposed above Stocker Creek (18.1 $mi.^2$), 13% of total mining disturbance in EFAC (25.9 $mi.^2$, adding disturbance in Stocker Creek), or 12% of total mining disturbance for the entire Armells Creek drainage (28.5 $mi.^2$, adding disturbance in WFAC; see Table 3). Proposed Area B amendment disturbance in Lee Coulee (0.33 $mi.^2$) would only amount to about 6% of total surface mining disturbance proposed in Lee Coulee (5.2 $mi.^2$), and only about 2% of total mining disturbance proposed for the entire Rosebud Creek drainage (14.6 $mi.^2$, adding disturbance in Miller and Hay Coulees, and Cow, Pony and Spring Creeks).

Proposed Area B mining in the EFAC drainage is obviously of much greater significance than in Lee Coulee. Disturbance in the proposed amendment alone is also of some significance in EFAC, particularly above Stocker Creek. However, as vegetative reclamation in Area B progresses from the initial bare cover to vegetative conditions similar to premining, only localized hydrologic responses are expected in surface water systems. Although the proposed WECO Area B amendment would place some additional burden on the cumulative surface water impacts of Colstrip area mining, it does not appear that premine surface water uses would be prevented after the proposed reclamation is completed. The Department therefore finds that no material damage to surface water systems would result with the proposed mining and reclamation in WECO's Area B amendment.

26.4.314 PLAN FOR PROTECTION OF THE HYDROLOGICAL BALANCE

This section describes the plan for protection of the hydrologic balance at the Rosebud Mine. Components of the premining hydrologic balance are described and detailed descriptions of protective measures to be taken during and after proposed mining activities are presented. This section also includes a description of the monitoring plan to determine probable hydrological consequences of the proposed strip mining operation on the mine plan area and the adjacent area.

Premining Hydrologic Balance: The hydrologic balance describes the relationships between all aspects of surface and groundwater quantity and quality including precipitation, runoff, evaporation, and changes in ground and surface water storage. Major components in the hydrologic balance are:

1. precipitation as rainfall and snow;
2. evaporation from open water surfaces and soils;
3. transpiration from plants;
4. interception of precipitation by vegetation;
5. infiltration of water into the soil and percolation to groundwater;
6. runoff both as overland and channelized flow;
7. storage of moisture in the soil and in ponds and reservoirs; and
8. recharge, discharge, and storage of water in groundwater systems.

Mining has the potential to change the hydrologic balance through possible changes in evapotranspiration, infiltration, runoff, soil moisture, or groundwater. Sedimentation ponds, diversion ditches, water treatment ponds, postmining recontouring, top soil replacement and revegetation are specifically designed to protect the hydrologic balance.

Exhibit 14

WCCPROD00001522

Hydrological Systems Components: Water input to the hydrologic system comes in the form of precipitation, including rain, snow, sleet, and hail. A portion of the precipitation is intercepted by vegetation. Some precipitation runs off or goes into storage in ponds, depressions, etc. Overland flow enters drainage channels and becomes streamflow. A portion of precipitation infiltrates into the soil, most of which provides water for plants, but some percolates downward recharging underlying groundwater systems. The majority of the precipitation is returned to the atmosphere by evapotranspiration which includes evaporation from water bodies and soil surfaces and transpiration from plants. Of the water that percolates downward to groundwater systems, some enters regional groundwater systems, some is held in the unsaturated zone between the soil surface and the water table, and some enters into local groundwater systems. Surface water flows commonly are sources of recharge to groundwater, particularly to alluvium underlying stream channels. Local and regional groundwater systems discharge to springs or to streams providing baseflow.

Precipitation: Precipitation has been measured at Colstrip from 1941 to the present. The long-term average annual precipitation at Colstrip for the period 1941 to 1985 is 15.5 inches. April, May, and June normally are the wettest months averaging 1.9, 2.5 and 3.3 inches, respectively. January and February are the driest months averaging 0.6 inches each (U.S. Department of Commerce, 1973). Extremes in precipitation since 1970 were 22.12 inches in 1978 and 7.66 inches in 1980. The wettest individual month during the 1970 to 1979 period was May, 1978 during which 9.3 inches of rainfall occurred. (U.S. Department of Commerce, 1979), average monthly (1941 - 1985) precipitation for Colstrip is

Exhibit 14
WCCPROD00001523

shown in Table 27, page 186. Precipitation Data for Colstrip are updated annually with the Annual Hydrology Report (HRDV I, Surface Water FLow Data). Precipitation data are collected by Western Energy at surface water sites using wedge-type gages.

From November to April, precipitation occurs predominantly in the form of snow which contributes approximately one-third of the total annual precipitation for the Colstrip area. Due to prevailing westerly winds, snow typically accumulates on leeward slopes of the north-south oriented drainages which are predominant in Area B.

Interception: Interception occurs when precipitation is caught by the vegetative cover and redistributed as throughfall, stemflow, and evaporation. Interception loss is the part of rainfall that is retained by the aerial portion of the vegetation and is either absorbed by the vegetation or is returned to the atmosphere through evaporation. Major factors in interception are vegetation type, density, form, and age. Water intercepted by vegetation is not available for infiltration. No site-specific data are available for interception losses for native vegetation in the Colstrip area. Horton (1919), however, developed a general relationship for clover and meadow grasses as follows:

$$I = 0.00042H + 0.00026HP$$

where I is interception in millimeters (mm)

H is the grass height in mm

P is precipitation in mm for an individual event

Horton's equation must be used with individual storm events; thus, it is difficult to apply to the Colstrip area on an average basis. To obtain an idea of magnitude of interception, assuming ten storms of equal duration in the

Exhibit 14
WCCPROD00001524

months of May and June, and five storms per month in July through October, and using a gross height of 150 millimeters (six inches) results in interception losses shown in Table 26, page 149. These values are less than, but agree reasonably well with empirical results published by the U. S. Soil Conservation Service (Dunne & Leopold, 1978) for interception losses in cropped areas of oats or wheat during the growing season (see Table 26).

Exhibit 14

WCCPROD00001526

Evapotranspiration: Evapotranspiration includes both evaporation from water and soil surfaces and the transpiration or use of water by plants. It is the principal path by which precipitation returns to the atmosphere. Quantitative measurements of evapotranspiration are very difficult to make, thus numerous indirect techniques have been developed to calculate evapotranspiration rates. There are several factors involved in evaporation and transpiration including temperature, wind, total heat input, vegetation type, and season. A widely used technique for calculating evapotranspiration is the Blaney-Criddle formula (SCS, 1970) which states:

$$E_t = (0.142\ T_a + 1.095)\ (T_a + 1.78)kd$$

where; E_t = potential evapotranspiration (cm/month)

T_a = average air temperature ($^\circ$C) (when T_a is less than 3°C, the first term in parenthesis is equal to 1.38)

k = empirical crop factor that varies with crop type and stage of growth

d = monthly fraction of annual hours of daylight.

Potential evapotranspiration (E_t) as calculated by this formula is defined as that evapotranspiration that would occur if the availability of water were not a limiting factor. Evapotranspiration values using the Blaney-Criddle formula are shown in Table 27, page 186.

Another common method for estimating evapotranspiration is the use of Class A pan evaporation data. Class A evaporation stations consist of a standard 4 foot diameter pan partially filled with water. Each day the amount of water

Exhibit 14
WCCPROD00001527

loss from the pan is determined and the water replaced. Pan evaporation data are relatively easy to obtain and pan data are widely available for estimations of evaporation.

Montana State University has collected land pan evaporation data at Peabody Coal Company's Big Sky Mine near Colstrip and Western Energy Company has collected pan evaporation data at the Rosebud Mine; results are in Table 28, page 187. Also, included in this table are U. S. Weather Service pan data from the Yellowtail Dam and the Huntley Project stations. Gray (1970) recommends applying a factor of 0.68 to pan evaporation data to estimate actual evapotranspiration. With a pan evaporation of 53 inches per year at Colstrip, and a pan factor of 0.68, actual evapotranspiration is estimated to be 36 inches per year. This compares reasonably well with evapotranspiration of 28 inches calculated by the Blaney-Criddle method. Dr. D. Dollhopf of Montana State University suggests a pan factor of 0.85 for the Colstrip area which results in a potential evapotranspiration value of 45 inches (Dollhopf, pers. comm., 1981).

Potential evaporation or evapotranspiration at Colstrip is large compared to precipitation. This condition is common and typical of semiarid areas with warm summers. Implications of these data are that loss of moisture by evaporation and evapotranspiration is a major factor in the hydrologic balance for any area of this type.

Another factor contributing to loss of moisture in an area is sublimation. Sublimation is a direct conversion of ice or snow to water vapor without passing through a water phase. Chow (1964) estimates sublimation losses in the middle latitudes during the winter season to be about 0.5 inches of water per month of snow cover. Snow normally occurs in the Colstrip area from November through March and accounts for approximately one-third of the total annual precipitation

Exhibit 14
WCCPROD00001528

for the Colstrip area. Thus, during this period sublimation could transfer about half of the precipitation (2.5 inches) occurring from November through March back into the atmosphere.

Infiltration: Infiltration is the movement of water through the soil/air interface. It involves three independent processes: entry through the soil surface, storage within the soil profile, and transmission through the soil. Infiltration of water into soils is affected by the soil type, antecedent moisture, organic matter, vegetative cover, subsurface permeability, watershed slope, and soil temperature.

A detailed soil survey was conducted in Area B in accordance with the standards of the National Cooperative Soil Survey (26.4.304(13)). Results of this survey were used to estimate infiltration rates in Area B. Most soils in the proposed mining area are derived from fine grained materials and are categorized into U.S. Soil Conservation Service Hydrologic Soil Group B. Infiltration rates for this group range from slow (0.06 in/hr) to moderately rapid (6 in/hr) and are shown in Table 29, page 188. A weighted average for the permit area is moderate (2.3 in/hr).

Due to the semiarid nature of this area, total depth of infiltration generally is not high. In areas where water accumulates, such as small depressions, ponds or channel bottoms, sufficient water is present to allow significant infiltration into the subsurface. The average infiltration rate of 2.3 in/hr for soils in Area B substantially reduces the amount of runoff in the basin. Most precipitation events in this area have intensities that are less than 2 inches per hour (5 cm/hr), thereby allowing infiltration to be a major

Exhibit 14
WCCPROD00001529

mechanism influencing runoff. This value of 2.3 in/hr compares with a value of 3.8 in/hr (average of 213 determinations at 18 sites on the Rosebud Mine determined using ring infiltrometers.

Runoff: When the rainfall or snowmelt rate exceeds the infiltration rate of the soil, water collects and flows overland to drainage channels. Area B primarily is drained by small ephemeral tributaries to East Fork Armells and Rosebud Creeks. Approximately 1907 acres or 91 percent of the disturbed area drains to East Fork Armells Creek, and 195 acres or 9 percent of Area B Extension drains to Rosebud Creek. Normally, no flow occurs in the ephemeral drainages within the permit area except during periods of intense rainfall or rapid snowmelt.

Two cutthroat flumes, one instrumented culvert, and five crest gages are currently utilized to measure streamflow in East Fork Armells Creek and ephemeral tributaries in Area B. Locations and installation descriptions are included in HRDV I (Surface Water Station Descriptions). Flow data are found in HRDV I (Surface Water Flow Data). An average annual water yield of 0.0185 acre-feet per acre has been estimated for Area B (26.4.308(8)(e) utilizing data from three U.S.G.S. gaging stations near Colstrip having similar drainage basin characteristics. Applying this value to the proposed disturbance area results in an average of 39 acre-feet or 0.2 inches of runoff per year from the 2102 acres. This estimated annual runoff is substantially higher than has been observed in the Colstrip area since Western Energy began monitoring surface water flows in 1979.

Sediment ponds in Area B (assuming all were in place at one time) might impound 0.8 percent of the average annual runoff for Armells Creek near Forsyth.

Exhibit 14

WCCPROD00001530

Estimated reduction in annual runoff for various other locations and tributaries are: 6.2 percent for Armells Creek above the mouth of Stocker Creek; 8 percent for Armells Creek at the highway near the eastern edge of Area B; 1.5 percent for Lee Coulee above Rosebud Creek; and 0.02 percent for Rosebud Creek above the Yellowstone River. This assessment is based on relative drainage areas only and neglects such factors as sediment pond discharges which are difficult or impossible to predict.

Soil Moisture: Soils can absorb significant quantities of water which infiltrate into the subsurface. Water moving into an idealized isotropic soil will satisfy the water holding or field capacity of the surface horizons before moving downward in response to gravity. After removal of the gravitational water, water still remains in the soils due to capillary and surface forces. The amount of water that the soils can hold after gravitational drainage is termed "field capacity". For soils in Area B, field capacities range from 0.06 inches/inch to greater than 0.13 inches/inch and average about 0.1 inches/inch as shown in Table 29, page 188. Assuming a layer of soil approximately 4 feet thick, the total amount of water that can be held in the soil is 4.8 inches. From this, it can be seen that the soils can be a major factor in water storage. This water is available for transfer to the atmosphere by evaporation or by transpiration through plants. Moisture is also held by soil and regolith materials at depths greater than four feet but above the water table where interaction with plants and the surface are less likely.

Soil moisture fluctuates in response to long-term climatic changes and shows annual fluctuations. Soils commonly are at their highest moisture content during spring and early summer when snowmelt and precipitation are maximum.

Exhibit 14
WCCPROD00001531

They become driest during the late summer when evaporation and transpiration have had their maximum effect. During the fall, soils tend to gain some water from precipitation. Methods for measuring soil moisture include laboratory analysis of samples collected from test borings, neutron scatter technique, and gypsum blocks; all of which have been used at the Rosebud Mine.

Soil moisture studies have been or are being conducted by Western Energy Company in Areas A, B, and C and by MSU at several locations in the Colstrip area to provide information on a variety of soil, vegetation and geomorphic situations. In Areas A, B, and C, a total of 18 sites, all on East Fork Armells Creek alluvium, were monitored monthly to depths of 8 to 12 feet (Hydrometrics, 1980). Results of this testing show that during the exceptionally dry period from June to October, 1980, soil moisture variations were small except in the upper few feet of the soil. The zone showing the most significant moisture fluctuations was the upper foot of the profile; soil moisture was lowest during the summer and increased slightly in the late fall.

Soil moisture readings for the 1981 growing season (June to October) along East Fork Armells Creek were compared to the 1980 data for the same period. Within the top three feet of the soil profile there were significant moisture variations due to precipitation events. However, below three feet, soil moisture for both years at specific depths were very similar, and varied at a maximum by five percent throughout the growing season. Some general trends were apparent in 1980 and 1981. Surface moisture to 3.0 feet declined from June to August or September, increasing in September or October with fall precipitation. Monthly variations in soil moisture below 3.0 feet were very small in most cases, fluctuating by one to three percent generally, and up to five percent in

Exhibit 14
WCCPROD00001532

one instance. The heavy rains at Colstrip during spring 1981 and early summer did not seem to affect subsurface moisture below 3.0 feet.

Soil moisture is also being evaluated at sites in Areas A and B in a continuation of Western Energy Company's infiltration study mentioned under Infiltration, Rule 26.4.304(5), and documented in HRRV V (Western Energy Co., 1982 and Western Energy Co., 1983). Gypsum blocks, evaporation pans, and precipitation gages were installed during the summer of 1984 at an undisturbed site in Area A and a reclaimed site in Area B. Mirco watersheds at each site were isolated with metal edging and equipped with catchment buckets. Preliminary analysis of data from this study, although not conclusive, seems to support the findings mentioned above.

Groundwater: Groundwater is present in shallow bedrock aquifers including coal seams, localized sandstone lenses and in unconsolidated alluvium present in large drainages in the area. In Area B, a number of groundwater observation wells have been constructed to observe water level fluctuations in the various aquifers and to determine the hydraulic properties of water-bearing zones (HRDV I, Groundwater Stations and Level Data, and HRDV III, Groundwater Hydrographs). Data obtained from these observation wells and detailed discussion of groundwater characteristics are in 26.4.304(5).

Groundwater Recharge: Groundwater recharge can potentially occur in the permit area through three mechanisms: 1) area wide infiltration and recharge, 2) lateral inflow from topographically high areas such as the Little Wolf Mountains, 3) infiltration and recharge in topographic low areas such as stream channels and depressions. The relative importance of these three mechanisms probably varies from mine area to mine area and probably also within mine areas,

Exhibit 14
WCCPROD00001533

particularly an area as large as Area B. Area wide infiltration and recharge could occur as a result of precipitation during late fall before the ground freezes--or in the spring as a result of snow melt, runoff, or precipitation after the ground has thawed. An annual infiltration of 0.06 inches could supply a potential outflow of approximately two gallons per minute from a one square mile area. Potentiometric surface maps suggest both regional recharge from the Little Wolf Mountains and area wide infiltration (HRRV I, Annual Report). Topographic lows, such as depressions and stream channels concentrate moisture and could become local point and line sources of recharge to underlying groundwater systems. Quantitatively, the contribution of such sites are unknown, difficult or impossible to quantify accurately, and vary from year to year. Overall, groundwater recharge from such sites is probably small, but may be locally significant.

Groundwater Discharge: A list of springs, their contributing aquifers and flows are presented in 26.4.304(8)(b), Table 1, page 58 and shown on the Surface Water Sites, Ponds, Springs, and Private Wells Map (HRDV I, Monitoring Schedule and Site Location Map). Evidence of discharge to surface water includes intermittent flow in East Fork Armells Creek and a number of springs or seeps in the headwaters of the Armells Creek drainage. During runoff, alluvium along the ephemeral streams may become saturated. These saturated sediments slowly drain and supply a short period of baseflow to these streams. East Fork Armells Creek contains two short segments which have continuous base flow during much of the year ranging from no flow to about 30 gpm (within Sections 8 and 15, T1N, R40E). The source of these discharges is believed to be alluvium, with contribution from Rosebud coal in Section 15. Above Section 15 (T.1N.,R.40E.), alluvium may

Exhibit 14
WCCPROD00001534

discharge to the Rosebud coal and/or overburden. The absence of larger and more numerous perennial segments of these streams suggests groundwater discharge to streams is not significant.

Groundwater Storage: The change in the amount of groundwater storage can be determined by assessing annual fluctuations in water levels and by determining the areal extent of aquifers underlying the area. Results of groundwater monitoring in the entire upper East Fork Armells Creek shows there is little fluctuation in groundwater levels in bedrock aquifers (HRDV II, Groundwater Hydrographs). However, alluvial aquifers tend to have a distinct seasonal fluctuation in response to the annual precipitation cycle.

Water bearing zones of interest in the permit area are the Rosebud overburden and Rosebud coal. The alluvial aquifer associated with East Fork Armells Creek will be disturbed by mining along the middle and upper terraces parallel to East Fork Armells Creek in Sections 11, 14, 15, 16, and 17 (T1N,R40E). Major changes in groundwater storage in the East Fork Armells Creek alluvium, however, are not expected and will not be considered here. During mining and reclamation, infiltration and discharge from sedimentation ponds and mine pits should mitigate the disruption of the headwater drainages.

Average annual water level fluctuations for Rosebud overburden and the Rosebud coal wells are approximately 1.1 and 0.8 feet, respectively (HRDV II, Groundwater Hydrographs). Multiplying these fluctuations by the areal extent of the aquifers and by the storage coefficient yields the change in groundwater storage. Storage coefficients for overburden and Rosebud coal are estimated to be 0.004 (see discussion under Rule 26.4.305(5)).

Exhibit 14
WCCPROD00001535

Using an average storage coefficient for both aquifers, changes in storage are estimated to be the equivalent of .05 and .04 inches of water for the Rosebud overburden and Rosebud coal seam respectively, for the mine permit area.

Rosebud Overburden

DS = DWL x Area x S

= 1.1 x 9490 acres x 0.004

= 41 acre/ft. or .05 inches

Rosebud Coal

DS = DWL x Area x S

= 0.8 x 9490 acres x .004

= 30 acre/ft. or .04 inches

DS = change in groundwater storage (acre-ft.)

DWL = change water level elevation (ft.)

Area = Area of aquifer (acres)

S = Storage coefficient

Neither the overburden nor the Rosebud coal underlie the entire permit area, so these estimates are high. These results indicate that changes in groundwater storage are relatively insignificant in the overall hydrologic balance.

Summary: From an evaluation of the components of the hydrological cycle, several important conclusions can be made:

1. Precipitation in the form of rainfall is the major input to the hydrological system and the period of major precipitation occurs during late spring and early summer which also is a period of high evapotranspiration.
2. Interception and subsequent evaporation result in about 0.5 to 1.0 inches of precipitation loss per year.

Exhibit 14
WCCPROD00001536

3. Evapotranspiration is the major mechanism for return of water to the atmosphere and is far more important than any other component of the hydrological cycle for transfer of water; calculated potential evapotranspiration is two to three times the average annual precipitation.
4. Sublimation of snow is an important mechanism for transfer of water to the atmosphere during late fall, winter, and early spring.
5. The infiltration capacity of soils in the proposed mining area is large compared to precipitation intensities in the area. This means that infiltration is an important mechanism for transfer of a significant percentage of precipitation into the soil, and surface runoff will occur only during significant precipitation events or following rapid snowmelt.
6. Soil moisture is an important but difficult to quantify component of the hydrological cycle; however, significant quantities of water are stored in the soil and subsequently removed by evaporation and transpiration.
7. Runoff to streams, groundwater recharge, and changes in groundwater storage are a small fraction of the precipitation input into the hydrological cycle.
8. Groundwater discharge contributes very little to the transfer of water from one component to another component or other components of the hydrologic cycle.

Exhibit 14

WCCPROD00001537

Exhibit 14

26.4.314 (1) (a): Mining in Area B will be done by dragline excavation. Pit orientation is shown on Exhibit A. Spoils will be regraded with crawler tractors. The general mining plan includes salvage of soil material from the mining area in advance of each pass. Average depth of topsoil salvage will be one foot. After topsoil is removed, subsoil will be removed by an average depth of about one foot. Scrapers and other mobile equipment will salvage, transport and deposit the soil materials on graded areas or in soil storage areas. Overburden stripping will be done with a dragline.

Mining impacts of hydrological importance that can occur are destruction of horizontal continuity in the overburden strata and mixture of the overburden strata in the backfilled pits creating a more isotropic media. During this process, some geological materials that were saturated are intermixed with unsaturated materials. In addition, a variety of lithologies are mixed including siltstones, sandstones and shales. The mining process substantially increases the surface area of excavated materials exposed to air and water. During the mining process, soil structure is altered, vegetation is removed, and the replaced subsoil and topsoil probably has a slightly increased bulk density.

The dragline removes overburden material by pulling the bucket upward from near the base of the cut toward the top. This material is then "cast" into spoil ridges in the preceding cut. As the stripped overburden material is cast, it is spread over a relatively large area, as much as perhaps 150 meters by 50 meters horizontally and 20 by 30 meters vertically. During this process, the materials are thoroughly mixed, and blocks of geologic materials tumble down steep spoil pile slopes and form a "rubble layer" at the base of the replaced spoils.

Exhibit 14
WCCPROD00001539

Moran et al (1979) conclude that the rubble zone is probably thin but has a substantially higher permeability than the original materials. Backfilled spoils have a higher porosity than the original strata and these spoils probably have a higher vertical percolation rate since the materials when backfilled are more isotropic. Most sedimentary materials exhibit a strong preferential horizontal permeability. At the ground surface, infiltration of precipitation has been shown to be comparable in reclaimed and undistrubed lands (HRRV V; Western Energy Co., 1982; Western Energy Co., 1983). This means that runoff will be similar to premining conditions.

Postmine spoils water quality has been estimated from overburden chemistry using the regression presented in Western Energy Company's 1983, Annual Hydrology Report (HRRV I, Annual Report). Average total dissolved solids concentration for Area B spoils is predicted to be about 3,000 mg/l, ranging from approximately 2,500 to 5,200 mg/l, as shown on Exhibit R. Overburden E.C's from 1,000 ft. grid holes were krigged to predict E.C's for 300 ft. blocks, and the regression was applied to the results. Premine TDS values for observation wells in Rosebud coal and overburden and private wells are tabulated in Table 30, page 189. Average spoils water TDS levels will be within the range found for private wells in Area B Extension and where sufficient quantities of suitable quality water are not available from spoils, adequate water supplies can be obtained from deeper horizons.

Measures will be taken to mitigate or eliminate all adverse impacts on water quality. If toxic or acid-forming overburden or mine wastes are present, they will be segregated during burial to avoid contact with groundwaters in accordance with 26.4.641. The excavation of pits will create a spoil ridge which will be regraded to its approximate original contour using bulldozers and

Exhibit 14
WCCPROD00001540

scrapers. Subsoil will be placed on regraded spoils to a uniform depth of about 1.3 feet. The subsoil will be overlayed with approximately 1.1 feet of topsoil. Treesoils will be placed to a uniform depth of 1.5 feet. During regrading and soil distribution, the drainages will be reconstructed to approximate the pre-mining drainage pattern and contour. Regrading and reclamation of mined areas will begin within a maximum of two spoils ridges of the pit. Following topsoil placement, and at the proper season, a seed bed will be prepared using a chisel plow and a farm tractor. Straw mulch will be incorporated into the soil on slopes steeper than 5:1. Fertilizer will be applied at a rate based on soil analyses. The prepared soil will then be seeded with appropriate seed mixtures (see also Sections 26.4.308 and 26.4.313).

As described in 26.4.315, all runoff from disturbed lands will be treated in sediment ponds. These ponds will be constructed in accordance with DSL and other applicable state and federal rules. Water discharged from these ponds will meet water quality standards and effluent limitations of the State of Montana and OSM. As described in detail in 26.4.633, a valid MPDES permit (Montana Pollutant Discharge Elimination System) will be obtained for all discharges from the proposed mining areas to public waters. This will assure protection of water quality in receiving waters in East Fork Armells and Rosebud Creeks.

26.4.314(1)(b) As described in 26.4.304(5)(b) there is no current use of the surface water in the proposed permit area except stock watering. Stock watering use of East Fork Armells Creek and Lee Coulee adjacent to and downstream from the mining area will not be significantly affected by the proposed mining activities. Downstream of the mine area changes in water quantity and quality are expected to have little effect on existing water uses.

Exhibit 14

WCCPROD00001541

Groundwater use in and adjacent to the proposed permit area has been described in Sections 26.4.304(5)(b), and 26.4.314(1)(a). Two wells, one of which is currently used for stock watering, will be removed by mining and seven other wells may be impacted as discussed in 26.4.304(5). During reclamation, replacement wells will be drilled that will provide water of adequate quantity and quality for intended postmining use as discussed under 26.4.304(5)(b) and 26.4.314(1)(a).

26.4.314(1)(c): Mining and reclamation plans for Area B presented in this permit application are designed to minimize impacts to both surface water and groundwaters. Reclamation of disturbed lands to approximate topography, vegetation, and soil conditions as described in the operations plan above are the principal procedures to be used to maintain premining runoff volumes from small ephemeral watersheds in Area B. Also, premining channel morphology and gradient are documented by longitudinal and cross-sectional channel profiles (Appendix D). This documentation will be used to reclaim channels to their approximate premining conditions. Temporary impacts of sediment ponds are addressed under 26.4.304(5) and 26.4.314(1)(a).

Aquifer properties of the postmine spoils aquifer are similar to those of the Rosebud Coal and Overburden (HRDV III, Aquifer Test Data). Infiltration rates for reclaimed surfaces have also been shown to be similar to infiltration rates for undisturbed areas (HRRV V, Western Energy Company, 1983), see also 26.4.304(5). Therefore, the quantity of groundwater available after mining will be similar to premine conditions.

Exhibit 14

WCCPROD00001542

Changes in groundwater quantity will be minimized by restoring recharge capacity as described in section 26.4.314(2)(c). Spoils will be backfilled as soon as possible in a manner designed to maintain the premining hydrologic balance. The alluvial aquifer associated with East Fork Armells Creek will be disturbed by mining activities along 12,600 feet of the middle and upper terraces parallel to East Fork Armells Creek.

Because the postmine topography will approximate the premine topography and recharge capacity will be restored, the net postmine ground and surface water flux will approximate premine conditions. Alluvial gravels are dry or only partially saturated throughout much of the 12,600 feet of alluvium that will be mined through. In this reach (Section 17 and the western 3/4 of Section 16) a reduction in cross-sectional flow area of the alluvium will not significantly alter alluvial flow rates. To the east (Section 15 and downstream) where the alluvial gravels are fully saturated (or nearly so), a reduction in cross-sectional flow area of the alluvium will result in a decrease in alluvial groundwater flow, an increase in surface water flow, and a possible increase in the eastward component of spoils water flow as compared with premine Rosebud coal and overburden flow.

To preserve the hydrologic balance, compacted clayey spoils will be placed against saturated gravels exposed in mine pits if premine alluvial water levels are higher than premine Rosebud coal water levels. Where the Rosebud coal now discharges to alluvium, the hydrologic connection will be maintained by simply spoiling directly against the gravel. When the spoils resaturate following mining and reclamation, flow in the alluvium will be maintained by inflow of spoils water. Downstream from Section 15, flows in undisturbed alluvium will be

Exhibit 14
WCCPROD00001543

essentially the same as premine flows. A reduction in alluvium ground water flow in Section 15 will be compensated for downstream by increased infiltration through the channel bottom from increased surface water flows. Past mining in Areas A and B has had no noticeable effect on vegetation along East Fork Armells Creek or on surface flow downstream from surface water station SW-55.

Where saturated gravels are to be mined, wells will be installed along the boxcut to dewater the alluvium which will be mined. Water will be pumped to East Fork Armells Creek at approximately E28,500 where it will be discharged to the channel and will ultimately return to the alluvial ground water system by infiltration through the channel bottom. Suspended sediment loads of ground water are normally less than 30 mg/1 so treatment should not be necessary to meet MPDES requirements.

Water levels in spoils wells in Areas A, B, and Pit 6 suggest that ground water levels and flow will fully recover within 10 to 20 years of final reclamation. A computer simulation done for the Final Comprehensive Environmental Impact study predicted that recovery would take hundreds of years, but recharge from sources such as sediment ponds, run off temporarily stored in mine pits, and area wide infiltration were not accounted for.

Mining cuts adjacent to alluvium will temporarily reduce ground water flow from bedrocks units to the alluvium. However, this reduction in recharge to the alluvium will have only a small effect on down stream alluvial flows (26.4.304(5)).

Exhibit 14
WCCPROD00001544

26.4.314(2)(a): Treatment and water control facilities for the proposed permit area are shown in Exhibit D. Treatment facilities are planned to impound drainage from all areas where soil has been salvaged, unless otherwise approved by the Department. There will be 15 sedimentation ponds with spillways in the proposed mining area and 97 sediment traps (seepage/evaporation ponds without spillways; see Figure 4, page 191). All impoundments are designed to contain the 10-year, 24-hour runoff volume. Spillways associated with sediment ponds will be designed to carry the peak discharge from the 25-year, 24-hour precipitation event.

Sedimentation ponds in series or parallel will be used in Drainage 129 and 136. These ponds will be installed sequentially as mining progresses. Sediment production and runoff records from the first pond may be used in developing final design for the remaining ponds. Sediment production will be monitored by comparing detailed surveys of initial impoundment dimensions with resurveyed bathometric contours, by core sampling to determine sediment volumes, or by other approved methods. Typical cross sections of proposed ponds are shown in Figures 5 and 6, pages 192 and 193.

At all times during mining, sedimentation pond volumes will be adequate to retain the 10-year, 24-hour runoff from disturbed lands above the ponds.

During mining, runoff from undisturbed land above the pit will be intercepted by the pit or by temporary impoundments or traps in the drainages above the pit. Very large runoff events will be intercepted by the pit. Interception by the pit insures that runoff will not cause water quality problems in East Fork Armells Creek and Rosebud Creek.

A system of ditches and traps proposed for the perimeter haul road is shown in Exhibit D. Ditches along the haul road direct runoff to either sedimentation ponds or sediment traps. In areas where the haul road crosses the ephemeral drainages, sediment traps will be provided to collect runoff from the road embankment. Ditches will roughly parallel access roads to intercept all runoff from disturbed lands. Through use of this containment system, Western Energy will prevent any sediment or untreated runoff from leaving the permit area.

Imported Pit Water:

Pit water from Big Sky Mine will sometimes be pumped to an inactive pit in Area B (MR03-03-03B). Exhibit A shows the approximate location of the pipeline and pit. Portions of this water will be used for dust suppression. The water may be directed to other pits within Area B and other permit areas within the Rosebud Mine depending upon operational needs. It is expected that using inactive pit areas for water storage will aid in the resaturation of the adjacent spoils. The water in the pit will not be allowed to rise above an elevation of 3393 feet and will be measured quarterly and reported in the Annual Hydrology Report. Two spoil wells will be installed during 2003 to monitor the resaturation of the spoils. The location of the wells will be determined in consultation with the Department.

WCCPROD00001545

Groundwater: Groundwater drainage to the pit will come from Rosebud overburden, Rosebud coal, and from alluvium/colluvium associated with ephemeral drainages. Western's mining plan will disturb a portion of the middle and upper terraces of the alluvial aquifer underlying East Fork Armells Creek. Groundwater flow in Rosebud coal and overburden through the area to be mined is small, probably on the order of 5 - 10 gallons per minute (26.4.304(5)). Potential flow from tributary alluvium/colluvium is also expected to be small. Groundwater inflow to the pit may periodically be pumped to sedimentation ponds. Some of this water will be used for dust suppression. When necessary, excess water will be discharged in accordance with Western's MPDES discharge permits.

Groundwater Inflow: Inflows from aquifers cut by the pits will be a combination of water released from storage and groundwater flow from the aquifer in response to natural hydraulic gradients. The inflow of groundwater released from storage in aquifers can be estimated analytically. A commonly used method is the line-sink equation (Walton, 1970). This equation assumes laminar flow, instantaneous release of water from storage, and isotropic conditions none of which are fully met by drainage from natural groundwater systems in rapidly excavated mine cuts. The very large flow rates implied by line-sink formula for initial inflows are incorrect. Due to convergence of flow at the free face, initial inflows will be lower than predicted; consequently, these inflow estimates should be regarded as maximums. The Darcy equation can be used to predict the "steady state" groundwater inflow from the aquifer system. The "steady state" groundwater inflow is

the continuous groundwater flow in the aquifer prior to mining in the sector cut by mining.

A significant complication in prediction of pit flows is the backfilling of pits with spoils. Spoils will be backfilled by the dragline after the coal is removed creating a temporary groundwater sink (until they resaturate) which will act as a partial barrier to groundwater inflow to the next successive cut. Actual pit inflows from storage also will depend greatly on the rate of vertical excavation into the aquifer and the time that elapses between cuts. There is no methodology that will accurately predict groundwater inflow from the complex cut and backfill mining proposed in this operation.

Results of pit and boxcut inflow calculations are presented below. Aquifer hydraulic coefficients and groundwater gradients are summarized in 26.4.304(5). Storativity is assumed to be .04 for alluvium and .004 for bedrock aquifers and transmissivities are 1,480 gpd/ft for alluvium, 276 gpd/ft for overburden, and 56 gpd/ft for Rosebud coal. A major simplifying assumption used in calculation of pit inflow is that during mining of successive blocks, groundwater drainage from previously mined blocks will not enter the new block. The rate of groundwater drainage from storage in each block decreases rapidly with time and the residual drainage from previous cuts would be small in comparison with water from a new cut. Each new cut is assumed to have full groundwater storage, that is, it has not been partially drained by a previous cut. It is assumed that each cut is opened instantaneously and that residual drainage entering previous cuts does not flow into new cuts. Thus, the first assumption leads to a slight underestimate of inflow and the others to a significant (possibly an order of magnitude) overestimate. Experience at the Rosebud Mine suggests that the inflow estimates are high.

Exhibit 14
WCCPROD00001547

Western's Area B Extension mining plan includes cutting through approximately 12,600 feet of alluvium adjacent to East Fork Armells Creek along the middle and upper terrace levels in Sections 15, 16, and 17 (T1N,R40E). Alluvium here consists of about 25 feet of silt overlying 5 - 10 feet of sandy gravels. Estimated inflow into the boxcut from exposed alluvium, overburden, and Rosebud coal would be approximately 2,990, 543, and 382 gpm at 1, 30, and 60 days, respectively. Boxcut inflow calculations assume that the entire boxcut is opened instantaneously. Because it will actually take several months to open the boxcut, this assumption may introduce an order of magnitude error in the calculations. Other than inflow from storage in East Fork Armells Creek alluvium over the short period the pit is open, little long-term inflow from this alluvial aquifer is expected and impacts on the alluvial system will be minor as discussed earlier in this section.

Flows from tributary gravels into the boxcut in the vicinity of East Fork Armells Creek are expected to be minor. Assuming a transmissivity of 250 gpd/ft, inflow from a combination of tributary alluvium, overburden, and Rosebud coal are about 0.017, 0.0031, and 0.0022 gpm/ft of cut (one face) for periods of 1, 30, and 60 days, respectively. The tributary alluvium is assumed to have a saturated thickness of five feet; however, alluvium often is dry in tributary channels throughout the Colstrip area. For a tributary alluvial channel 100 feet wide, inflow to a boxcut is estimated to be 1.7, 0.3, and 0.2 gpm at 1, 30, and 60 days, respectively.

Exhibit 14

WCCPROD00001548

2. (b) Sedimentation ponds will be designed for total containment of discharges of the 10-year, 24-hour precipitation event from disturbed areas in the proposed mine area. Locations of sedimentation ponds and associated diversion ditches are shown on the Drainage Plan, Exhibit D and are described in 26.4.314(2)(a). All discharges will be in accordance with 26.4.633 and will be discussed in further detail in Western's application for a MPDES permit associated with Area B Extension outfall sites.

2. (c) As part of the mining reclamation plan, overburden will be replaced in the excavations, regraded to approximate original contour, and covered with subsoil and topsoil. Because existing materials are replaced in the pits and existing subsoils and topsoils are salvaged for replacement on the regraded surface, spoils and postmine soils will be similar in lithology to existing materials. The vegetative cover will be reestablished on the reclaimed topography. Soils in the portions of Area B to be mined are nearly all silt loams, sandy loams, and loams. There will be about 2.4 feet of topsoil and subsoil replaced over the spoils in the reclaimed areas. The replaced soils will be similar in texture to the premining soils but the soil structure will be altered. Infiltration rates for undisturbed and reclaimed areas near Colstrip have been evaluated by Western Energy Co., in 1982, and 1983 (HRRV V) as discussed in 26.4.304(5), and 26.4.314. Infiltration into these soils (that is, movement of water through the soil air interface into the soil), is a function of soil texture, structure, vegetative cover and slope. These four factors will be similar in the postmining soils and the overall infiltration capacity of these soils will be similar to premining infiltration capacity as shown by the above mentioned studies. The downward movement or percolation of water through

Exhibit 14
WCCPROD00001549

the soils is, in part, controlled by the field capacity of the soils. Much, if not all, of the initial infiltration will be retained by the topsoil. These soils have a field capacity of 0.06 to 0.13 in/in (Table 29, page 188) which means they can hold three to six inches of water before any deep percolation will occur. Such large accumulations of water will seldom occur in these soils. Spoils material placed beneath the topsoil will be a variety of lithologies but will dominantly be silt. In the process of strip mining, the individual strata are intermixed and the porosity is increased. In most geological materials, the horizontal permeability is many times greater than the vertical permeability. After strip mining, however, the soils will become more isotropic; that is, permeability will be similar in all directions including the vertical direction. This indicates that percolation rates through the spoils potentially could be higher than in premining conditions. The amount of water that percolates into the spoils, however, will be controlled by the movement of water through the topsoil. Much of the water moving into the topsoil will subsequently be removed by evapotranspiration and will not be available for percolation. It is expected that the potential rate of percolation will be much greater than the availability of water and that evapotranspiration out of the topsoils will be a controlling process in recharge capacity of the reclaimed mine land. Regraded spoils will be scarified prior to placement of topsoils. This will insure that there is no impermeable barrier at the soil-spoils interface.

The overall impact of mining on recharge capacity in Area B has both regional and local aspects. Regional impacts to lands and water from mining near Colstrip were assessed in a Comprehensive Environmental Impact Study (DSL and OSM, 1983). Locally, in and adjacent to these lands, the general lithology, vegetative cover and topography will be similar to premining conditions. There probably is a

Exhibit 14
WCCPROD00001550

small amount of groundwater recharge to bedrock aquifers in the area to be disturbed by mining in Area B, and the location of all regional sources of recharge are not completely known (see section 26.4.314(1)). Recharge areas probably will function after mining as they did before mining; however, in groundwater systems with very low flows, accurate determination of recharge locations and volumes is difficult. Reclamation of mined lands to approximate premining conditions particularly along the principal stream courses, will do much to mitigate the effects of mining on recharge capacity.

Transmissivity of the spoils in reclaimed land near Colstrip has been measured by Western Energy Company (HRDV III, Aquifer Test Data) and the Montana Bureau of Mines and Geology (Van Voast, Hedges, and McDermott (1977)). MBMG spoils transmissivity data range from 0.7 to 479 gpd/ft with a lognormal mean of 33 gpd/ft for 11 observation holes compared with a range of 10 to 12,715 gpd/ft and a lognormal mean of 109 gpd/ft for the Rosebud coal. Aquifer test data collected by Western Energy Company for ten spoils wells show transmissivities ranging from 28 to 2955 gpd/ft with a lognormal mean of 253 gpd/ft. Aquifer test data collected by Western Energy Company show a range of 3.4 to 4,500 gpd/ft for 15 overburden wells with a lognormal mean transmissivity of 103 and a range of 0.5 to 1,650 gpd/ft for 29 Rosebud coal wells with a lognormal mean transmissivity of 31 gpd/ft. These data suggest that the transmissivity of the spoils will be higher than transmissivities in undisturbed bedrock units (Rosebud coal and Rosebud overburden). Spoils transmissivity is low, however, and overall groundwater movement in the spoils probably will be similar in magnitude to that in the existing bedrock units.

Exhibit 14
WCCPROD00001551

The overall impact of mining in Area B to recharge capacity is expected to be small and relatively short-term. The reclaimed lands should function hydrologically in a similar manner to the existing system. East Fork Armells Creek alluvium is the most important aquifer in the area in terms of flow and significant changes in water quality or quantity in the alluvial system that would affect present uses are not expected to result from the proposed mining.

Drawdown effects of mining in the Colstrip area were predicted with a three-dimensional computer model (DSL and OSM, 1983). Results indicate drawdowns of several tens of feet within a mile of active pits. While results of the model are not exact, they do indicate that total recovery to premining water levels may take several hundred years. Allowing a small amount of area wide infiltration (even less than .5 in./yr.) would significantly increase the rate of recovery. Water level data for Pit 6 suggest 10 to 20 years for recovery.

Total dissolved solids concentrations in the spoils aquifer will increase over premining concentrations in the Rosebud coal and Rosebud overburden. Although total dissolved solids concentrations will increase, water quality will still be acceptable for stock watering, the primary premining use.

2. (d) The hydrology monitoring program for Western Energy's Colstrip operations, including Area B, consists of periodic collection of surface water quality and quantity data, groundwater quality and groundwater water level information as shown in the Monitoring Schedule (HRDV I, Monitoring Schedule and Site Location Map). It should be recognized that representative measurement of surface water characteristics in the ephemeral drainages within the proposed permit area, is logistically and technically difficult.

Exhibit 14
WCCPROD00001552

Western Energy's annual reports summarize data collected in each year and the projected hydrological monitoring program for the next year. The location of all surface water and groundwater monitoring sites are shown on the hydrologic monitoring sites map (HRDV I). Details of the monitoring plan specific to this proposed mining plan in Area B are contained in Sections 26.4.645 and 26.4.646.

Probable hydrologic consequences of mining on surface water are discussed in 26.4.304(9), 26.4.314, 26.4.314(1)(a), 26.4.314(1)(b), 26.4.314(1)(c), and 26.4.314(2)(a). Probable hydrologic consequences of mining on groundwater are discussed in 26.4.304(5), 26.4.304(5)(b), 26.4.304(9), 26.4.314, 26.4.314(1)(a), 26.4.314(1)(b), 26.4.314(1)(2), 26.4.314(2)(a), and 26.4.314(2)(c).

In addition to the material presented elsewhere in the permit and referenced above, Western Energy Company analyzed impacts to the water quality of the alluvial groundwater systems adjacent to the Rosebud Mine using a computer model. The model was used in the Area C, Block II permit application to evaluate the impacts of mining as proposed in Western Energy Company's application on the alluvial water quality of East Fork Armells Creek and spring along West Fork Armells Creek and East Fork Armells Creek and to evaluate the impacts of mining with and without a 500 foot buffer zone between the East Fork Armells Creek and the boxcut. This model uses a flow net analysis and postmine water quality predicted from overburden E.C. to estimate postmine water quality changes to alluvial aquifer systems. Overburden E.C.'s on 1,000 ft. centers were krigged to estimate E.C.'s for 300 ft. blocks and the krigged values were run through a

Exhibit 14

WCCPROD00001553

regression equation relating overburden E.C. to spoils water quality (Exhibit R). Existing aquifer test and water quality data for the area modeled were used when available. Where data were not available, values interpolated from nearby data points were used. Water levels used in the model are presented in HRDV II (Groundwater Stations and Level Data). Water quality data are presented in HRDV III (Groundwater Quality Data), aquifer properties are found in HRDV III (Aquifer Test Data) and the potentiometric surface for the Rosebud coal is presented in HRDV 1 (Annual Report). Cross sections for East Fork Armells Creek, Stocker Creek, West Fork Armells Creek, Cow Creek, and South Fork Cow Creek alluvium at locations where aquifer properties are known have been drawn. Cross-sections were not drawn for Lee Coulee or Miller Coulee. A cross-section prepared by Dollhopf, et al (1981) and aquifer data provided by Peabody Coal Co. (Koffler, 1986, and Wheaton, 1986) were used for those watersheds. The cross-sections are assigned locations based on the distance up-stream along an imaginary alluvial flow path. Cross-section locations with mile designations and assumed flow paths are shown on Exhibit S. Alluvial aquifer data for each section was input to the computer on two or more data lines (first data page for each analysis, Appendix F). The first line contains the gradient, average premine total dissolved solids, mile designation, and the number of wells in the cross-section. The second and subsequent lines contain the permeability and cross-sectional flow area for each well. Cross-sections are presented for each stream following the alluvial aquifer input data.

Exhibit 14

WCCPROD00001554

A flow-net (Exhibit S) was constructed for the bedrock aquifer using the potentiometric surface for the Rosebud coal as presented in HRRV I augmented by data from Dollhopf, et al (1981). Input data to the program for the bedrock aquifers (second and subsequent data pages for each analysis, Appendix F), consist of a data line with the number of cells or elements in each flow path and the mile point along the assumed alluvial aquifer flow path, followed by data lines for each element or cell consisting of a line containing the width and length of the element; a line containing the Rosebud coal transmissivity, gradient, premine total dissolved solids; a line containing overburden transmissivity, gradient, premine total dissolved solids; and the estimated postmine total dissolved solids on the last line. If an element will not be mined, a flow weighted average of overburden and Rosebud coal TDS values was input for the postmine TDS. Input data are presented in Appendix F. Output from the model consists of plots of TDS versus time for the various alluvial cross-sections under consideration. These are presented in Appendix F following the input data. In most cases estimated impacts to alluvial groundwater quality for most of the drainages under consideration are very small because the flow rates through the bedrock aquifers and estimated flow rates through the spoils are very small in comparison to flow rates through the alluvium.

In its present form, the model routes dissolved solids along a single alluvial flow path; so for this analysis, tributaries were handled by ignoring the tributary alluvium and assuming that the bedrock flows enter the main stem alluvium at the confluence with the tributary. This will not introduce appreciable error because the alluvial flow times are short relative to the length of the analysis. For some areas to be mined, it is known that no direct connection exists with the alluvial aquifer associated with the stream draining the area.

Exhibit 14
WCCPROD00001555

It was assumed that these areas would not impact alluvial groundwater quality. Areas where the degree of alluvial connection was unknown were assumed to impact alluvium, even though in some cases a direct connection is extremely unlikely (i.e. Cow Creek tributatries draining the northeast quarter of Section 25, T2N,R41E; and the northwest quarter of Section 30, T2N,R42E; or Stocker Creek tributaries draining Sections 2 and 3, T1N,R40E.

The relatively large impacts predicted for alluvial sections at miles 1.1 and 1.7 on East Fork Armells Creek result primarily from the small alluvial flows for those cross-sections of 13 and 23 gpm respectively. The estimated alluvial groundwater flow for the cross-section at 3.3 miles is 63 gpm. This significant reduction in alluvial groundwater flow coupled with total dissolved solids inputs from Areas A and D, the power plants, and the ash pond combine to produce an estimated 2.5 fold increase in TDS at 1.1 miles. The several hundred thousand gallons per day of relatively low TDS (about 1,200 mg/l) water from the sewage treatment plant was not accounted for in this analysis because it is not known how much actually enters the groundwater system. A small percentage of sewage treatment plant effluent entering the alluvial groundwater system would result in a significant reduction in predicted impacts.

Power plant impacts were factored into the analysis by assuming that 1,000,000 gallons of water per year with a TDS of 15,000 mg/l might enter the alluvial groundwater system. Montana Power Company's ash pond in Section 29, T2N,R41E, was simulated by setting the post-disturbance TDS of a bedrock flow element equal to 15,000 mg/l. Impacts of the plants represent about 300 mg/l at 1.7 miles and the ash pond represents about 50 mg/l at 1.1 miles.

Exhibit 14

WCCPROD00001556

Impacts of mining in Area C Amendment, on East Fork Armells Creek were evaluated in detail in that permit (pages 383 through 383d). Input data for that analysis were updated with new information and was incorporated into this analysis. Impacts of mining on springs along West Fork Armells Creek were also evaluated in the Area C Amendment permit (pages 383d through 383f). Because the alluvium is not continuous below Springs SP-36 and SP-37, impacts to the springs will not affect alluvium downstream. Therefore, that analysis was not incorporated into this effort. Impacts of mining in Area D on Spring SP-24 are found on pages 42 through 42d of that permit (SMP 86003-D). Because Pony Creek alluvium is not continuous below SP-24, mining in Area D is not expected to impact alluvial groundwater quality downstream.

Predicted impacts to Lee Coulee and Miller Coulee are signigicant for the first 20 years after mining. Predicted increases in total dissolved solids concentrations (4,200 mg/l for Lee Coulee and 1,700 mg/l for Miller Coulee) in alluvial groundwater near Rosebud Creek are higher than expected because Western Energy Company does not know the mining sequence at the Big Sky Mine. So, mine blocks assumed for the model were large which would tend to compress the time period over which impacts occur and increase the peak change. Little is known about alluvial aquifer properties and cross-sections for either drainage, so input parameters had to be estimated from data reported by Dollhopf, et al (1981) and Peabody Coal Company (Koffler, 1986, and Wheaton, 1986). Bedrock aquifer properties and gradients were estimated from information provided by Peabody Coal Co. (Koffler, 1986, and Wheaton, 1986) and reported by Dollhopf, et al (1981). Because Western Energy Company did not have access to actual potentiometric surface maps for the Big Sky Mine area, the potentiometric surface was approximated using data presented by Dollhopf, et al (1981). Because

Exhibit 14
WCCPROD00001557

of time contraints and uncertainties about the flow system, the flow net was drawn assuming as a worst case that all mining at Big Sky would contribute groundwater flow to either Lee or Miller Coulee. As a result of this assumption, the flow patterns do not fit the potentiometric contours precisely, but the results will give a conservative estimate of impacts to the alluvial system.

Impacts to Rosebud Creek were computed by summing the maximum increase in mass transport for Miller Coulee, Lee Coulee, South Fork Cow Creek, and Cow Creek (5.1×10^8 mg/day) and comparing that figure to the average mass transport for Rosebud Creek near Colstrip (USGS station 0695250, mass transport = 1.2 x 10" mg/day). Maximum impacts for all four streams were assumed to reach Rosebud Creek simulataneously and, because Western Energy Company has no information on groundwater flow rates or water quality for Rosebud Creek alluvium, the entire change in mass transport predictd by the model was assumed to impact surface water quality. Under these assumptions the predicted change in total dissolved solids under average flow conditions would be about 0.4 percent or from about 950 mg/l to 954 mg/l.

November 1, 1988	Final EIS Issued

Exhibit 13

II. Environmental Setting

Peabody has applied to the Department of State Lands (DSL) and the Office of Surface Mining Reclamation and Enforcement for a new mining and reclamation permit in Lee Coulee (Area B). The new permitted acreage would be 5,435.8 acres, of which 3,200 acres are proposed to be disturbed.

Several environmental assessments have been prepared by the Department and the federal government for Peabody's previous permits, proposed mining operations, or actions associated therewith. These include:

Montana Department of State Lands. November, 1973. Draft Environmental Impact Statement, Peabody Coal Company, Big Sky Mine.

U.S. Geological Survey and Montana Department of State Lands. September 1979. Final Environmental Statement, Proposed Expansion of Mining and Reclamation Plan, Peabody Coal Company, Big Sky Mine, Rosebud County, Montana.

U.S. Geological Survey and Montana Department of State Lands. 1980. Environmental Statement, Regional Analysis, Northern Powder River Basin Coal, Montana.

Montana Department of State Lands. September 1983. Technical and Environmental Assessment for Repermitting and Revision, Peabody Coal Company, Big Sky Mine, Rosebud County, Montana.

Montana Department of State Lands. March 1986. Preliminary Environmental Review, Peabody Coal Company's Big Sky Mine, Area B Proposal, Rosebud County, Montana.

Montana Department of State Lands and U.S. Office of Surface Mining Reclamation and Enforcement. April 1987. Preliminary Environmental Review, Snider's Amendment, Peabody Coal Company, Big Sky Mine, Area A.

Montana Department of State Lands and U.S. Office of Surface Mining Reclamation and Enforcement. July 1988. Draft Environmental Impact Statement, Peabody Coal Company, Big Sky Mine, Area B, Rosebud County, Montana.

The final EIS for Area B is in preparation.

Montana Department of State Lands and U.S. Office of Surface Mining Reclamation and Enforcement. November 1988. Final Environmental Impact Statement, Peabody Coal Company, Big Sky Mine, Area B, Rosebud County, Montana.

III. Evaluation of Compliance

This section will evaluate for compliance the mining and reclamation plan that Peabody has proposed in its application.

A. Mine Plan and Coal Conservation

Peabody would mine only the Rosebud coal seam using the conventional form of single-seam mining called area mining. The permit application and the draft EIS (DSL and OSMRE, 1988) describe the mining method and the sequencing in great detail. The McKay coal seam is not proposed to be mined at this time. This is due to Peabody's customer not wanting the McKay coal because of its high sulfur content and the resulting air quality concerns with respect to sulfur dioxide. Therefore, the McKay coal seam is considered unmarketable at this time by Peabody. DSL concurs with this position.

Another concern is the avoidance of a minable coal reserve of state-owned coal located in the northeastern corner of Section 36, T1N, R40E. The total amount of affected coal is 541,200 tons. The coal conservation directives of the regulations require the state to maximize the recovery of economically minable coal within logical mining units. Due to leasing terms, the state is unable to grant a lease at this time. Therefore, Peabody has committed in its permit application to pursue obtaining a coal lease and submit an amendment application once an appropriate time frame is reached to satisfy all concerns.

The DSL has determined that Peabody's mine and coal conservation plans are in compliance with all rules and regulations of Montana's permanent program.

B. Reclamation Plan

Reclamation would concentrate on returning the area to the historic land uses of native rangeland for livestock grazing and wildlife habitat. Livestock grazing may be enhanced by better distribution of water after mining. Areas of concentrated shrub and tree plantings would be established to promote habitat diversity. Two bluff extensions are proposed around Marmot Peak. These bluff extension plans include a contingency plan demonstrating highwall reduction and backfilling if further slope stability analyses prove to demonstrate instability.

The DSL has determined that Peabody's reclamation plan is consistent with the rules and regulations.

C. Overburden Handling

After mining is completed, bulldozers and scrapers would be used for final grading to move spoil material to achieve the desired land form. Rough backfilling and grading would be completed within 180 days following coal removal. Prior to applying soil, the spoils would be ripped to a depth of 12 to 24 inches.

The overburden within the proposed permit area consists primarily of sandstone with some occurrence of siltstone and shale. Overburden analyses

revealed that the majority of the strata proposed for disturbance are of suitable quality. However, any unsuitable or marginally suitable overburden encountered would be adequately mitigated by either dilution, blending, or selective handling (if necessary). Some textural problems were noted as a few strata were high in either sand or clay. These particular strata would be effectively mixed in the process of mining.

D. Soils, Vegetation and Land Use

Soil material would be salvaged utilizing a two-lift salvage technique. Soil salvage depths for soil mapping units within the permit area range from 0 to 3 feet, depending on limitations (i.e., depth to bedrock, rock fragment content, texture, or other parameters) as indicated in the pre-mine soil survey. Soil material would be replaced over regraded spoil to a depth of approximately 1.5 feet. Some special handling of "tree soil" (coarse textured soils with greater than 35 percent rock fragments) would be required in order to promote the successful establishment of Ponderosa pine in the post-mining phase.

In general, soil handling would be performed in a manner which is consistent with the act and regulations.

Revegetation would be conducted in accordance with DSL rules and approved procedures by seeding or planting a variety of predominantly native species of grasses, forbs, trees and shrubs to return the area to native rangeland for the historic land uses of livestock grazing and wildlife habitat.

E. Hydrology

1. Surface Water

Protection of the hydrologic balance during mining and reclamation activities would be provided by an approved drainage and sediment control system and continuation of the hydrologic monitoring program as approved by DSL.

Post-mine impacts to drainages would be minimized by the development of approximate original topography and concave longitudinal stream profiles with some changes in channel gradients, sinuosities, and drainage densities in the reclamation plan. The potential for erosion and instability from the increases in runoff and peak flow volumes predicted for some reclaimed channels would be minimized by establishment of a native vegetation cover and stable channels designed to pass the runoff from a 100-year, 24-hour precipitation event.

Post-mine increases predicted for dissolved solids (e.g., TDS, sulfate) in surface waters impacted by mining are expected to be small, with improvement as the vegetative cover is established and as spoils aquifer quality improves gradually.

Removal of three seasonal upland ponds would be mitigated for by the addition of a well with a livestock tank and a "wildlife watering facility", a protected overflow pond designed to provide water for species that can't use

the livestock tank and aquatic and riparian habitat. To mitigate for the loss of five wells to be removed by mining and as a parital mitigation for loss of surface water in the coulee bottom, five wells with livestock and wildlife watering faciliites would be established on the proposed permit area after mining. The replacement wells would be distributed to complement livestock and wildlife usage. Peabody has also committed to consulting with DSL where monitoring indicates the potential for opportunistic development of permanent surface water sources (e.g., final cut impoundments, the reestablished Marmot Peak tributary, leaving sediment ponds or spring development).

A stream buffer study zone has been proposed for the upper "wet reach" of Lee Coulee to remain undisturbed for the first five years of mining. Peabody would conduct hydrologic and biologic monitoring during that period to determine the extent and characteristic of the aquatic habitat. Peabody would then propose either mine plan changes or specific mitigation for mining all or part of the "wet reach" based on the monitoring results. In either case, Peabody has committed to protecting the "Turtle Pond area" from mining disturbance for the life of operations, and proposes enhancement of this area as a general mitigation for surface water impacts.

Details of these and less significant hydrologic impacts are described in the Lee Coulee permit application and in the Draft Environmental Impact Statement.

2. Groundwater

The proposed mining would physically disrupt the upper three aquifers in Lee Coulee; the alluvial (silt, sand and gravel) aquifers, the overburden (siltstone, sandstone and shale) aquifers, and the Rosebud coal aquifer. Connections may exist between these upper aquifers and underlying aquifers; if so, disruption of the upper aquifers may affect the pressure of the deeper aquifers by increasing the permeability of the confining layer.

The Rosebud coal aquifer is generally under semi-confined conditions in the mine area, but becomes unconfined where the Lee Coulee channel has eroded into it. In the upper part of the Lee Coulee drainage, it appears that shale underlying the Rosebud coal creates a mounding of groundwater that then discharges through the unconfined coal and overburden aquifers to the alluvium. This increases storage in the alluvial aquifer and results in several perennial pools of surface water in the ephemeral drainages. The reach of this type in the Lee Coulee drainage is referred to as the "wet reach" in the permit application. Disruption of the coal and overburden aquifers adjacent to the wet reach may have the effect of diminishing the extent of surface water. As mitigation, the operator has committed to increasing surface water resources downgradient of the affected part of the wet reach, opportunistic development of surface water resources and establishment of "wildlife watering facilities" in the form of stock tank overflows.

During mining the open pit would act as a groundwater sink causing local drawdown. The operator has committed to replacing water supplies affected by the mine. The operation would remove five stock wells; these would be replaced during reclamation with deeper wells.

Mining is expected to degrade groundwater quality due to the exposure of fresh mineral surfaces in the spoil to groundwater. The water can then solubilize these minerals resulting in an increase in salts. Previous mining in the drainages adjacent to the north, in Area A, has caused an average increase in total dissolved solids (TDS) of approximately 150 percent; however, a few Area A monitoring wells have shown water quality degraded to a greater degree. Most spoil groundwater in Area A, although degraded in quality, still meets the applicable beneficial use criteria for livestock grazing and wildlife. Similar post-mine water quality is expected in the Lee Coulee drainage. The operator has agreed, at DSL's request, to commit some of the spoil monitoring wells to monitoring conditions which may contribute to elevated TDS levels, such as the anomalously high levels found in some wells in Area A. Monitoring wells would be installed in an area with potential for upward leakage from underlying aquifers and in an area used for timber disposal (to attempt to determine if gaseous by-products of organic decomposition are increasing chemical reactions in the spoil).

F. Wildlife

Wildlife-related issues of concern for mining in Area B are: sharp-tailed grouse dancing ground removal, raptor nest site disturbance, surface water source removal, aquatic habitat destruction, and sandstone outcrop elimination.

One active sharp-tailed grouse dancing ground (Arena B-1), located along Lee Coulee, would be removed by mining. The combination of 1) availability of existing leks within proximity to Arena B-1, 2) revegetation plans designed to reestablish the topographic and vegetative characteristics of Arena B-1, and 3) the DNR Sharp-tailed Grouse Mitigation Plan, should mitigate impacts to regional sharp-tailed grouse populations and maximize the potential to reestablish Arena B-1 after mining.

A golden eagle nest (NW¼NE¼, Section 30, T1N, R41E) and a prairie falcon aerie (NW¼SW¼, Section 24, T1N, R40E) are located immediately adjacent to proposed disturbance areas. The U.S. Fish and Wildlife Service believes that mining can proceed without adversely impacting the eagle nest if a buffer zone with a one-half mile radius is established around the nest. Should mine-induced disturbance to the eagle pair be documented (i.e., two consecutive years of nest non-use while mining within the one-half mile buffer zone), Peabody Coal Company would construct artificial nests at suitable, known perching sites. Disturbance to the prairie falcon eyrie is not anticipated. Peabody Coal Company has agreed to monitor this nest site for nesting and territorial activities and to create or enhance additional eyrie sites in adjacent sandstone bluffs before mining begins in Area B.

Lee Coulee is one of the few reliable sources of surface water for wildlife in the permit area. Peabody Coal Company is committed to replacing any surface water sources that may be lost to mining. Planned mitigation includes enhancement of the Turtle Pond area, which will not be disturbed for the life-of-mine, and opportunistic development of water enhancement features such as final cut impoundments, sediment ponds or springs. Peabody Coal Company also proposes to install six wells with stock tanks, each of which will be equipped

with wildlife escape ramps and an overflow to a catchment basin or pond. The overflow areas would be protected from livestock and enhanced to partially mitigate for loss of coulee bottom habitat. Since this is a human-maintained source of water, it cannot be guaranteed to provide water for wildlife beyond the life of the mine. Specific plans would be developed during consultation between Peabody Coal Company and the Department prior to implementation of any of the above surface water replacement mitigation plans.

Lee Coulee may support a "biological community" which could preclude mining. Peabody Coal Company has established a stream buffer study zone around Turtle Pond and the "wet reach" of Lee Coulee (see Surface Water section).

Mining would eliminate some sandstone outcrops and natural bluffs. To mitigate for the resultant loss of wildlife habitat, Marmot Peak would not be removed. To mitigate for the loss of any potential eyries and to encourage nesting by golden eagles and prairie falcons, one or two eyries would be created in each of the two bluff extensions left on Marmot Peak, depending on the bluff's size and other physical characteristics. Eyries would also be developed in an existing bluff that is currently used as a nesting site for prairie falcons just northwest of the proposed permit area.

G. Cultural Resources

With the redefinition of sites 24RB1163 and 1164, Peabody has made the necessary eligibility determinations for all eight sites identified within the proposed permit area. Mitigation plans had already been submitted and approved for all sites. With the revised plan for the redefined 24RB1164, Peabody has also met the mitigation plan requirement for all eight sites. This completes the company's pre-permit obligations.

Peabody would have to complete the approved mitigation measures, including submitting a satisfactory final report, for each site prior to receiving approval to disturb the site; this will be stipulated (see section V). The company has also committed to protecting the sites from vandalism, etc. in the interim.

Requests were made to the Northern Cheyenne and Crow Tribes for any information they might have on culturally or religiously significant sites in the proposed permit area and immediately adjacent areas. The Crow Tribal Council replied that no significant resources of this nature were present in these areas. No response was received from the Northern Cheyenne Tribal Office.

H. Bonding

Bonding levels proposed by Peabody for Area B have been reviewed and found adequate for the initial five-year permit term. The bonding analysis identifies the worst-case scenario during the permit term and calculates an adequate reclamation cost estimate. The total bond amount required is $3,469,987.00. Peabody will be submitting this amount just prior to permit issuance.

IV. Findings

1. The Montana Department of State Lands has determined that the permit application submitted in 16 volumes, submitted on October 7, 1987, and revised through October 1988, is complete and accurate and the applicant has complied with Montana's permanent regulatory program (82-4-222, MCA), subject to the proposed stipulations described in Section V.

2. The applicant has demonstrated that reclamation, as required by the Montana Strip and Underground Mine Reclamation Act and regulations, can be accomplished under the reclamation plan contained in Volumes 12 through 16 of the permit package, and as subsequently revised (82-4-227(1), MCA), subject to appropriate stipulations referenced above.

3. The Department has determined that the new permit application known as Area B for the Big Sky Mine is:
   a. Not within an area under study or administrative proceedings under a petition to have an area designated as unsuitable for strip or underground coal mining operations (82-4-227(9), MCA).
   b. Not included in an area designated unsuitable for strip or underground coal mining operations pursuant to 82-4-227(9), MCA.
   c. Not on any lands subject to the prohibitions or limitations of 82-4-227, MCA, to include national parks, refuges, forests, etc.; nor where adverse impacts to publicly owned parks of places included in the National Register of Historic Places, public roads and buildings, occupied dwellings and cemeteries would occur.
   d. Not mining on any lands within 100 feet, horizontally, of the outside right-of-way line of any public road.
   e. Not mining within 300 feet, horizontally, of any occupied dwelling.
   f. Not mining within 300 feet, horizontally, of any public building, church, school, community or institutional building, or public park.
   g. Not mining within 100 feet, horizontally, of a cemetery where human bodies are interred.

4. Peabody has acquired all surface and mineral rights necessary to conduct operations for all areas proposed to be permitted and bonded.

5. The Department has made an assessment of the probable cumulative impacts of all anticipated coal mining on the hydrologic balance of the cumulative impact area. This includes: previous and existing mining in Peabody's Big Sky Mine (Area A), Western Energy Areas A, B, C, D, E, Pit 6 and Northern Pacific's pre-law mining, and proposed mining (Peabody Coal Company - Lee Coulee (Area B) and Western Energy Company's Area C Amendment). The assessment does not include mining previously alluded to by Peabody for Richard Coulee to the south of Area B, since that plan is uncertain and no details have been submitted. A Preliminary Environmental Review including an assessment of probable cumulative hydrologic impacts would be undertaken with submission of an application for mining in Richard Coulee.

   It has been determined that the proposed plan has been designed to prevent material damage to the hydrologic balance outside the permit area (82-4-

227(3)(a), MCA). The following is a summary of the Department's assessment:

The proposed mining is contained entirely within the Lee Coulee drainage, a minor tributary (20.61 square miles or about 1.6 percent) of Rosebud Creek (1302 square miles). Peabody's Big Sky Mine (Area A) to the northeast of Lee Coulee will include 1699 acres of disturbance by the upcoming completion of permitted mining (see SMP 83004CR). Total permitted area for the Lee Coulee (Area B) proposal would be 5436 acres, of which 3247 would be disturbed by mining (including the mined area, the area upon which spoil is to be deposited and graded, and where final highwalls will be reduced; see Exhibits 12-2, 20-2 and Figure 20-2, Peabody Coal Company Area B Application, 1988). The proposed disturbance represents 33 percent of the upper Lee Coulee drainage (9849 acres above Schmidt's Ditch, the lower limit of mining) and 25 percent of the total Lee Coulee drainage area. The probable hydrologic impacts to the surface water system within the permit area are summarized above (Evaluation of Compliance). Minor impacts are predicted for the surface water system outside the permit area (DEIS, MDSL/OSMRE 1988). This includes an approximate 2 percent increase in TDS at the mouth of Rosebud Creek (based on average annual flow) which could be somewhat higher during low flow months or years.

Impacts are expected to the coal, overburden and alluvial aquifers within the permit area. Average TDS increase in the spoil aquifer is predicted to be 2.3 times the pre-mine values, at a maximum, for the disturbed aquifers. The impact to the Rosebud Creek alluvial aquifer outside the permit area is predicted to be an 11 percent rise in TDS (Draft EIS MDSL/OSMRE, 1988). This increase in TDS may affect land management practices, or cause impacts outside the permit area where the local water table is very near to the surface; existing subirrigated areas consist largely of deep-rooted alfalfa and for this reason, impacts to existing beneficial uses are expected to be minimal.

The upper Rosebud Creek drainage, above the USGS gauge near Colstrip (one mile below the mouth of Lee Coulee), contains approximately 799 square miles (511,360 acres). Of this, approximately 9,800 acres will eventually be disturbed as a result of previous, existing and proposed mining plans. This includes: Peabody Areas A (1699 acres) and B (3247 acres); Western Energy (WECO) Area B Extension (195 acres on the upper Lee Coulee/East Fork Armells Creek divide), part of Area D West and all of Area D East (approximately 2530 acres), Areas E and E Extension (1086 acres), and Pit 6 (approximately 700 acres). The total disturbed area represents approximately 1.2 percent of the total Rosebud drainage, and the Lee Coulee disturbance represents about 0.6 percent of the upper Rosebud Creek drainage.

6. No structures currently exist in Area B. Peabody will construct minor facilities, i.e., mine office and fuel storage to help facilitate the operation. Other mine facilities are contained in Area A, which is under permit and in compliance with 82-4-222(2)(i), MCA, and pursuant regulations. The facilities in Area A will be used to support mining operations in Area B.

7. Peabody has paid all reclamation fees from previous and existing operations as required by 30 CFR Chapter VII, Subchapter R (OSMRE Applicant Violators System, November 10, 1988).

8. The following special categories of mining are not applicable to the proposed mining operation: special bituminous mining (30 CFR 785.12(c)), experimental practices mining (30 CFR 785.13(d), mountain top removal mining (30 CFR 785.14(c)), steep slope mining (82-4-232(2), MCA), prime farmlands (82-4-227(5), MCA), variance for delay in contemporaneous reclamation requirements (30 CFR 785.18(c)), areas in or adjacent to alluvial valley floors (82-4-227(3)(b), MCA), augering (ARM 26.4.326), coal processing plants or support facilities not located within the permit area (ARM 26.4.327), and in-situ processing activities (ARM 26.4.904).

   There is no designated prime farmland located within the permit area because the permit area does not contain a developed and dependable irrigation water supply.

   Pursuant to 82-4-232(7), the applicant has proposed alternate reclamation with respect to the leaving of bluff extensions around Marmot Peak (See B. Reclamation Plan). This constitutes a variance from AOC as currently defined. The Department has determined that the applicable rules have been met with this proposal.

   An alluvial valley floor is not present in Area B because the Department has determined that Lee Coulee and its tributaries meet the definition of upland areas, and therefore, do not satisfy the geologic criteria of an alluvial valley floor (see AVF Decision Document for Lee Coulee, MDSL, June 1987).

9. There is no proposal for an intensive agricultural post-mining land use within the proposed permit area.

10. The proposed operation would not affect the continued existence of threatened or endangered species or result in the destruction or adverse modification of their critical habitats, as determined under the Endangered Species Act of 1973 (16 U.S.C. 1531 et seq.) (Memo from Acting State Supervisor, Mt. State Office, USFWS to Chief, Federal Lands Branch, OSMRE, August 2, 1988).

11. There are no private family burial grounds within the permit area (personal communication with Reg Hoff, Peabody Coal Company on October 3, 1988), 82-4-227(7), MCA).

12. According to the records of the Montana Department of State Lands, no outstanding violations exist on the current operation. Further, no strip or underground coal mining and reclamation operation owned or controlled by Peabody Coal Company or related entities is currently in violation of the Montana Strip and Underground Mining Act or any federal law, rule or regulation pertaining to air or water environmental protection that has not

been or is not in the process of being resolved (82-4-227(11), MCA). (AVS check of November 10, 1988; filed in application file No. 00132.

13. Records of the Montana Department of State Lands and OSMRE show that the applicant does not control and has not controlled strip or underground coal mining and reclamation operations with a demonstrated pattern of willful violations of the Act of such nature, duration, and with such resulting irreparable damage to the environment that would indicate an intent not to comply with the provisions of the Act (82-4-227(12), MCA). (AVS check of November 10, 1988; filed in application file No. 00132).

Exhibit 13

V. Stipulations

26.4.1131

Peabody Coal Company shall complete the approved mitigation measures, including submittal of a satisfactory final report, for each of the cultural/historical sites that are eligible for listing on the National Register of Historic Places and that will be disturbed, before approval is granted to disturb these sites.

THE MICHIGAN ENTOMOLOGICAL SOCIETY

1986–87 OFFICERS

President	Mark F. O'Brien
President-Elect	Kenneth Kraft
Executive Secretary	M. C. Nielsen
Journal Editor	D. C. L. Gosling
Newsletter Editor	Louis F. Wilson

The Michigan Entomological Society traces its origins to the old Detroit Entomological Society and was organized on 4 November 1954 to " . . . promote the science of entomology in all its branches and by all feasible means, and to advance cooperation and good fellowship among persons interested in entomology." The Society attempts to facilitate the exchange of ideas and information in both amateur and professional circles, and encourages the study of insects by youth. Membership in the Society, which serves the North Central States and adjacent Canada, is open to all persons interested in entomology. There are four paying classes of membership:

Student (including those currently enrolled as college sophomores)—annual dues $4.00
Active—annual dues $8.00
Institutional—annual dues $20.00
Sustaining—annual contribution $25.00 or more
Life—$160.00

Dues are paid on a calendar year basis (Jan. 1–Dec. 31).

Memberships accepted before July 1 shall begin on the preceding January 1; memberships accepted at a later date shall begin the following January 1 unless the earlier date is requested and the required dues are paid. All members in good standing receive the *Newsletter* of the Society, published quarterly. All Active and Sustaining Members may vote in Society affairs.

All dues and contributions to the Society are deductible for Federal income tax purposes.

SUBSCRIPTION INFORMATION

Institutions and organizations, as well as individuals not desiring the benefits of membership, may subscribe to *The Great Lakes Entomologist* at the rate of $15.00 per volume. The journal is published quarterly; subscriptions are accepted only on a volume (4 issues) basis. Single copies of *The Great Lakes Entomologist* are available at $4.25 each, with a 20 percent discount for 25 or more copies sent to a single address.

MICROFILM EDITION: Positive microfilm copies of the current volume of *The Great Lakes Entomologist* will be available at nominal cost, to members and bona fide subscribers of the paper edition only, at the end of each volume year. Please address all orders and inquiries to University Microfilms, Inc., 300 Zeeb Road, Ann Arbor, Michigan 48106, USA.

Inquiries about back numbers, subscriptions and Society business should be directed to the Executive Secretary, Michigan Entomological Society, Department of Entomology, Michigan State University, East Lansing, Michigan 48824, USA. Manuscripts and related correspondence should be directed to the Editor (see inside back cover).

AN ANNOTATED LIST AND NEW SPECIES DESCRIPTIONS OF COLLEMBOLA FOUND IN THE PROJECT ELF STUDY AREA OF MICHIGAN [1]

Richard J. Snider and Frank J. Calandrino [2]

ABSTRACT

An annotated list of 80 collembolan species taken from the ELF Project area in Dickinson County, Michigan, is presented. Two new species are described, a new record for the United States is established, and new records for Michigan's Upper Peninsula are reported. Specimens were obtained using pitfall traps and extraction of litter and soil cores taken from deciduous forest.

The United States Navy Electronic Systems Command during 1981 was directed by the President to proceed with completion of an ELF (Extremely Low Frequency) communications system for submarines. This entailed the construction of a 58-mile-long antenna in Michigan's Upper Peninsula. Since 1982, our research team has been monitoring the deciduous forest arthropods associated with soil and litter of locations in Dickinson County. Our purpose is to establish baseline data about the composition and ecology of those populations before, during, and after erection and operation of the antenna.

Selection of suitable forest sites for study depended upon similarities of vegetation, soils, and climatic factors. During 1982 two sites were selected for initial investigations to validate methods, gather preliminary samples for analysis, and train our staff. One site, "Silver Lake" (T44N-R29W-S19), was used to evaluate the effects of spacing between pit-traps on catch (Snider and Snider 1986). The site is dominated by *Populus grandidentata* Michx., with *Acer saccharum* Marsh subdominant. Another site, "Turner Road" (T43N-R29W-S8), was looked at in 1982. *Acer saccharum* dominated, with *Tilia americana* L. subdominant.

Definitive sites for the ecological monitoring program were finally selected in 1983; these are designated "test" (T44N-R29W-S25) and "control" (T43N-R30W-S11). Both locations are dominated by *A. saccharum* with *T. americana* subdominant. Both soils are well drained spodosols. The A horizon in both sites is a mull, including small amounts of poorly developed moder. Climate conditions are given in Snider and Snider (1986).

The Collembola taken between summer of 1982 and 1985 were obtained by several collecting methods: pit-traps with and without barriers, day and night pickups; litter samples extracted by the Tullgren funnel method; soil cores and squares, Tullgren method; and hand collecting under logs, bark, and sweeping with white enamel pans. All specimens were preserved in 95% ethanol and, when necessary, examined as slide mounts with phase-contrast microscopy.

Previous records of Collembola taken in Michigan are available in Bernard (1973, 1976, 1977), Snider (1967a, 1967b, 1969a, 1969b, 1978), Snider and Fisher (1964),

Exhibit 12

Snider and Husband (1966), and Snider and Snider (1986). In the following account,published records are designated LP (Lower Peninsula), UP (Upper Peninsula), DC (Dickinson County), followed by tier, range, and section. The system of classification follows Christiansen and Bellinger (1981). United States and Canadian distribution records are also taken from Christiansen and Bellinger (1981). Additions to the U.S. list are from Bellinger (1982) and Fjellberg (1984, 1985).

We have collected 80 species from the ELF Project area of which two are species new to science, one is recorded in the United States for the first time, 29 are new Michigan records, and 15 are new records from the Upper Peninsula.

Order COLLEMBOLA
Suborder ARTHROPLEONA
Family HYPOGASTRURIDAE
Subfamily HYPOGASTRURINAE

Hypogastrura (Hypogastrura) nivicola (Fitch), 1846. LP, UP, T44N-R29W-S25, 16–17 July, night pit-trap. While this species, known as "the snow flea," has been observed by many people, mostly hikers and hunters, it has not actively been collected and recorded with frequency. The specimens were adult with fully developed black pigmentation. A species common in the northern half of the United States.

Xenylla acauda Gisin, 1947. UP, DC, T43N-R30W-S11, 7 May–15 Oct. from litter and soil cores; T44N-R29W-S25, 15 May–28 July, from litter and soil cores. U.S. records: California and Idaho.

Xenylla pallescens (Scott), 1960. T43N-R30W-S11, 22 May–17 July, litter and pit trap; T44N-R29W-S25, 22 May–3 July, pit-trap. Our studies show this species to be day-active. U.S. records: Colorado and New Mexico.

Willemia denisi Mills, 1932. T43N-R29W-S8, 10 Aug.–22 Oct., litter. U.S. records: Alaska (Fjellberg 1985), California, Colorado (Fjellberg 1984), Washington. Canadian records: Alberta and Northwest Territories.

Willemia intermedia Mills, 1934. LP. T43N-R29W-S8, 10 Aug.–16 Oct., litter and soil cores. Frequently taken with *W. denisi* and *W. similis*. U.S. records: California, Colorado (Fjellberg 1984), Connecticut, Iowa, Massachusetts, Tennessee, Utah. Canadian records: Quebec.

Willemia similis Mills, 1934. T43N-R29W-S8, 25–30 Aug., litter and soil cores. U.S. records: Arctic Alaska, California, Colorado (Fjellberg 1984), Indiana, Iowa, Kansas, Tennessee, Utah. Canadian records: Northern Canada.

Subfamily Neanurinae

Odontella substriata Wray, 1952. UP, DC, T43N-R29W-S8, 25–30 Aug., litter and soil cores. U.S. records: Connecticut, Illinois, North Carolina.

Friesia sublimis Macnamara, 1921. T43N-R29W-S8, 10 Aug.–22 Sept., litter. U.S. records, Connecticut, Illinois, Indiana, Massachusetts, New Hampshire, New York, Pennsylvania, Vermont (Bellinger 1982). Canadian records: Arnprior.

Pseudachorutes aureofasciatus (Harvey), 1898. LP. T43N-R30W-S11, 8 May–16 Oct., pit-trap. Our largest numbers were taken from diurnal pit traps. U.S. records: California, Connecticut, Illinois, Indiana, Iowa, Maine, Maryland, Montana, New York, North Carolina, South Carolina, Tennessee, Vermont (Bellinger 1982), West Virginia. Canadian records: Alberta, British Columbia, Quebec.

Pseudachorutes indiana Christiansen and Bellinger, 1980. T43N-R30W-S11, 7 May–7 Aug.; T44N-R29W-S25, 30 Aug.–29 Sept., litter. U.S. records: Alaska (Fjellberg 1985), Colorado (Fjellberg 1984), Indiana, West Virginia.

Pseudachorutes saxatilis Macnamara, 1920. LP, T43N-R30W-S11, 15 May–20 Oct.;

Exhibit 12

T44n-R29W-S25, 15 May–20 Oct., litter, soil cores, pit-traps. Diel studies using pit-traps show this species to be predominantly day-active. Immature specimens were taken from soil cores: adults were litter inhabiting. U.S. records: Indiana, Iowa, Maryland, North Carolina, Pennsylvania, South Carolina, Tennessee, West Virginia. Canadian records: Ontario.

Anurida (Anurida) granaria (Nicolet), 1847. T43N-R30W-S11, 21 May–20 Oct.; T44N-R29W-S25, 7 May–29 Sept., litter soil cores. This species appears to prefer the soil-litter interface. U.S. records: Alaska, California, Connecticut, Illinois, Indiana, Iowa, Kentucky, Massachusetts, New York, North Carolina, Vermont (Bellinger 1982), West Virginia. Canadian records: Ontario, Northwest Territories, Quebec, Ellesmore Is.

Anurida (Micranurida) furcifera (Mills), 1934. T43N-R29W-S8, 16 Aug.–16 Oct., litter and soil cores. U.S. records: Connecticut, Iowa.

Anurida (Micranurida) pygmaea (Borner), 1901. LP, T43N-R29W-S8, 25 Aug., litter. U.S. records: Alaska (Fjellberg 1985), Colorado (Fjellberg 1984), Connecticut, Iowa, Kentucky, Maryland, Massachusetts, Vermont (Bellinger 1982) West Virginia. Canadian records: Alberta, Manitoba, Northwest Territories, Ontario, Quebec.

Neanura (Neanura) muscorum (Templeton), 1835. LP, UP, DC, T43N-R29W-S25, 7 May–16 Oct., litter, under bark, soil cores and pit-traps. This species appears to be active at night. It is frequently encountered in our samples. U.S. records: Arizona, California, Colorado, Connecticut, Idaho, Illinois, Indiana, Iowa, Louisiana, Maine, Maryland, Massachusetts, Minnesota, New Hampshire, New Jersey, New York, North Carolina, Ohio, South Carolina, Tennessee, Utah, Vermont (Bellinger 1982), Washington, Virginia. Canadian records: Hudson Strait, Manitoba, Ontario, Ungava Bay.

Family ONYCHIURIDAE

Onychiurus (Archaphorura) affinis Agren, 1903. T43N-R29W-S8, 10 Aug.–22 Oct., litter. U.S. records: Colorado (Fjellberg 1984). Canadian records: Alberta, Manitoba, Quebec, Northwest Territories.

Onychiurus (Archaphorura) allanae Christiansen and Bellinger, 1980. T43N-R30W-S11, 28 July–20 Oct.; T44N-R29W-S25, 15 Aug.–20 Oct., litter and soil cores. U.S. records: Massachusetts, Oregon.

Onychiurus (Protaphorura) encarpatus Denis, 1931. T43N-R30W-S11, 21 May–15 Oct., litter and soil cores. U.S. records: California, Illinois, Indiana, Iowa, Kentucky, Louisiana, Maryland, Massachusetts, Missouri, New York, North Carolina, Ohio, Pennsylvania, Utah.

Onychiurus (Protaphorura) parvicornis Mills, 1934. T43N-R29W-S8, 10 Aug.–4 Oct., litter. U.S. records: Connecticut, Illinois, Indiana, Iowa, Massachusetts, Missouri, Vermont (Bellinger 1982), West Virginia.

Onychiurus (Protaphorura) similis Folsom, 1917. T43N-R29W-S8, 16 Aug.–16 Oct., T43N-R30W-S11, 7 May–20 Oct.; T44N-R29W-S25, 28 July–29 Sept., litter and soil cores. U.S. records: California, Connecticut, Illinois, Indiana, Iowa, Kentucky, Maine, Massachusetts, New Mexico, Texas, West Virginia, Wisconsin. Canadian records: Quebec.

Onychiurus (Protaphorura) talus Christiansen and Bellinger, 1980. T43N-R30W-S11, 16 Oct., pit- trap. U.S. records: New Hampshire, Oregon, Wisconsin.

Tullbergia clavata Mills, 1934. T43N-R30W-S11, 7 May–15 Oct.; T44N-R29W-S25, 28 July–20 Oct., soil cores. U.S. records: Idaho, Illinois, Indiana, Iowa, New York, North Carolina, Ohio, South Carolina, Tennessee, Utah, West Virginia. Canadian records: Quebec.

Tullbergia granulata Mills, 1934. LP, T43N-R29W-S8, 10 Aug.–16 Oct., T43N-R30W-S11. 7 May–20 Oct.; T44N-R29W-S25, 28 July–20 Oct., litter and soil cores. U.S. records: Colorado, Connecticut, Georgia, Illinois, Indiana, Iowa, Maryland, Massa-

Exhibit 12

chusetts, Missouri, New Hampshire, North Carolina, South Carolina, Utah, West Virginia, Wisconsin. Canadian records: Manitoba, Quebec.

Tullbergia mala Christiansen and Bellinger, 1980. T43N-R29W-S8, 16 Aug.–16 Oct.; T43N-R30W-S11, 7 May–20 Oct.; T44N-R29W-S25, 28 July–14 Sept., litter and soil cores. This is a very common species in litter and soil cores. U.S. records: Colorado, Connecticut, Illinois, Iowa. Canadian records: Alberta.

Tullbergia yosiii Rusek, 1967. T43N-R30W-S11, 7 May–20 Oct.; T44N-R29W-S25, 15 Aug.–20 Oct., litter and soil cores. U.S. records: Connecticut, Indiana, Iowa, Kentucky, Louisiana, Maine, New York. Canadian records: British Columbia.

Family ISOTOMIDAE

Anurophorus (Anurophorus) altus Christiansen and Bellinger, 1980. T43N-R29W-S8, 22 Sept., litter. U.S. records: New York, Pennsylvania.

Anurophorus (Anurophorus) septentrionalis Palissa, 1966. T43N-R30W-S11, 7 May–15 Oct., litter and soil cores. U.S. records: Alaska, Colorado, Connecticut, Illinois, Kentucky, Maine, Massachusetts, New Mexico, North Dakota, Oregon, Washington. Canadian records: Nova Scotia.

Anurophorus (Pseudanurophorus) binoculatus (Kneseman), 1934, T43N-R29W-S8, 22 Sept.–11 Oct.; T43N-R30W- S11, 7 May–20 Oct.; T44N-R29W-S25, 7 May–20 Oct., litter, pit-trap, soil cores. Most of the collection was taken in litter, only a few in soil cores. U.S. records: Colorado (Fjellberg 1984), Connecticut, Massachusetts, Tennessee.

Proisotoma (Proisotoma) minima (Absolon), 1901. LP, T43N-R29W-S8, 12 Aug.–22 Sept.; T43N-R30W- S11, 7 May–10 Sept.; T44N-R29W-S25, 7 May–15 Oct. litter and soil cores. U.S. records: Connecticut, Iowa, Louisiana, Massachusetts, New York, North Carolina, Tennessee, Utah. Canadian records: Quebec.

Cryptopygus decemoculatus (Folsom), 1937. T43N-R30W-S11, 8 May–20 Oct.; T44N-R29W-S25, 7 May–20 Oct., litter and pit-trap. U.S. records: Idaho, Illinois, Utah, Washington.

Folsomia bisetosa Gisin, 1953. T43N-R30W-S11, 16 Sept., soil core. Canadian records: Ellesmere Is.

Folsomia nivalis (Packard), 1873. LP, T43N-R29W-S8, 10 Aug.–22 Oct.; T43N-R30W-S11, 7 May–20 Oct.; T44N-R29W-S25, 16 July–20 Oct., litter and soil cores. U.S. records: California, Colorado, Connecticut, Idaho, Illinois, Indiana, Iowa, Kentucky, Maine, Maryland, Massachusetts, Montana, New Jersey, New York, North Carolina, Pennsylvania, South Dakota, Tennessee, Texas, Utah, Virginia, West Virginia, Washington, Wisconsin, Wyoming. Canadian records: British Columbia, Manitoba, Northwest Territories, Nova Scotia, Quebec.

Isotomiella minor (Schaeffer), 1896. LP, T43N-R29W-S8, 11 Oct.; T43N-R30W-S11, 7 May–15 Oct.; T44N-R29W-S25, 7 May–15 Oct., soil cores. U.S. records: Colorado, Connecticut, Idaho, Illinois, Indiana, Iowa, Maryland, Massachusetts, Missouri, New Jersey, New York, North Carolina, South Carolina, Tennessee, Utah, Vermont (Bellinger 1982).

Isotoma (Desoria) creli Fjellberg, 1978. T43N-R30W-S11, 8 May–16 Oct., pit-trap. U.S. records: Alaska.

Isotoma (Desoria) nigrifrons Folsom, 1937. LP, UP, DC, T43N-R29W-S8, 10 Aug.–22 Oct.; T44N-R29W-S19, 3 Aug.–8 Oct.; T43N-R30W-S11, 7 May–16 Oct.; T44N-R29W-S25, 7 May–16 Oct., litter, soil cores, pit-trap. This species and *I. notabilis* are very numerous in our samples. U.S. records: Colorado, Illinois, Iowa, Montana, Tennessee, Utah, Vermont (Bellinger 1982), West Virginia, Wyoming.

Isotoma (Desoria) notabilis Schaeffer, 1896. LP, T43N-R30W-S11, 7 May–16 Oct.; T44N-R29W- S25, 7 May–15 Oct., litter, soil cores, pit-trap. U.S. records: ubiquitous.

Exhibit 12

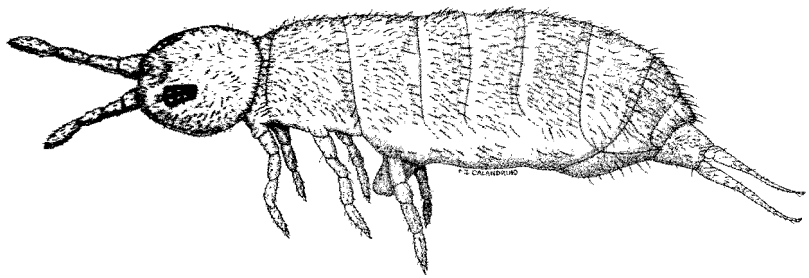

Fig. 1. *Isotoma (Desoria) nympha* n.sp. Habitus, drawn from specimen on microscope slide.

Isotoma (Desoria) nympha **n.sp.**
(Figs. 1–11)

COLOR AND PATTERN (Holotype, on slide): (Fig. 1). Body uniformly blue, with whitish intersegmental bands, pale or pigmentless areas on tergites and head. Head with dark blue pigment extending from frons posteriorly between the eyepatches and narrowing to form a dark spot medio-dorsally posterior to eyepatches, white patches medially anterior to eyepatches, V- shape mark extending from dark spot towards posterior edge of eyepatches. Antennae darker towards tip. Legs, manubrium and furcula lightly pigmented.

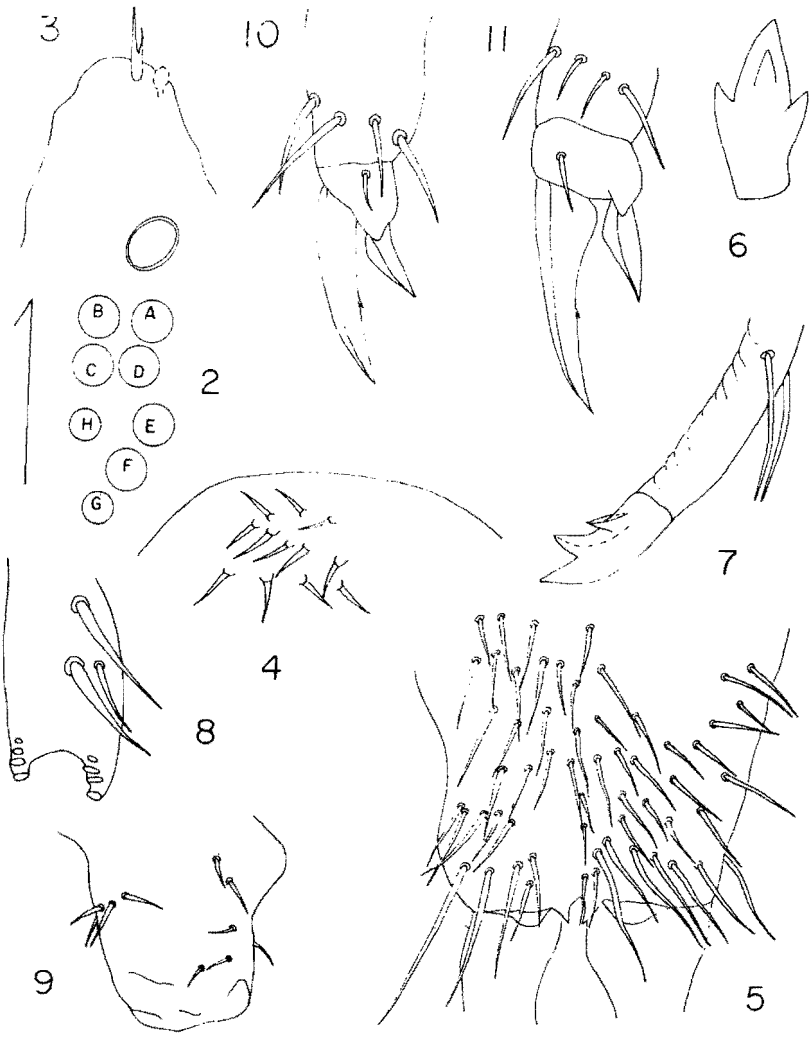
HEAD: eyes 8+8 with dark pigment, ocelli G and H subequal (Fig. 2). Postantennal organ elliptical, one and one-half as long as diameter of nearest eye. Apex of fourth antennal segment with "pin" seta and well developed secondary seta, subapical organ spherical (Fig. 3). First antennal segment without modified sensory setae on ventral surface. Labrum without visible ciliations (Fig. 4).

BODY: Abd. V–VI separate with smooth macrochaeta ranging from 2.5 to 4 times as long as inner hind unguis. Manubrium with free apical teeth and approx. 56 ventral setae (Fig. 5). Dens with many dorsal crenulations. Mucro quadridentate with apical tooth the longest and basal teeth subequal and on same level (Figs. 6–7). Retinaculum with 3 setae (Fig. 8). Collophore with 1 frontal seta, 5 lateral and 4 caudal setae (Fig. 9). unguis with minute inner tooth unguiculus with no corner tooth (Fig. 10–11). Length, 1.1mm.

DIAGNOSIS: *Isotoma (Desoria) nympha* n.sp. keys out nearest to *Isotoma (Desoria) japonica* Yosii in Christiansen and Bellinger (1981). However, besides morphological characteristics, color pattern will separate the two species. The following will distinguish the species

I.(D.) nympha	*I.(D.) japonica*
subapical antennal organ spherical	peg-like
unguis without lateral tooth	lateral tooth
56 ventral manubrial setae	16 setae
basal teeth of mucro subequal	unequal

Exhibit 12



Figs. 2–11. *Isotoma (Desoria) nympha* n.sp. (2) right ocellar patch, (3) apex of 4th antennal segment, (4) labrum, (5) manubrium, ventral view, (6) mucro, dorsal view, (7) mucro, lateral view, (8) retinaculum, (9) collophore, lateral view, (10) foreleg, claw, (11) metaleg, claw.

TYPES: Holotype and one paratype on slides. All types deposited in the Entomology Museum, Michigan State University.

Collection data: Michigan, Dickinson County T43N-R30W-S11, barrier pitfall trap 28-VI-84 and 16-VIII-84.

Exhibit 12

Isotoma (Isotoma) viridis Bourlet, 1839. LP, UP, DC, T43N-R29W-S8, 4 Oct.; T44N-R29W-S19, 3 Aug.–8 Oct.; T43N-R30W-S11, 7 May–27 Oct.; T44N-R29W-S25, 7 May–16 Oct., litter, soil cores, pit-trap. U.S. records: ubiquitous.

Family Entomobryidae
Subfamily Entomobryinae

Orchesella ainsliei Folsom, 1924. LP, UP, DC, T44N-R29W-S25, 4 Aug., pit-trap. U.S. records: Illinois, Indiana, Iowa, Kentucky, Louisiana, Maryland, Minnesota, Missouri, New York, North Carolina, South Carolina, Tennessee, Virginia, West Virginia, Wisconsin, Texas. Canadian records: Ontario.

Orchesella hexfasciata Harvey, 1895. LP, UP, DC, T43N-R29W-S8, 25 Aug.–22 Oct.; T43N-R30W-S11, 7 May–27 Oct.; T44N-R29W-S25, 8 May–0 Oct., T44N-R29W-S19, 3 Aug.–5 Oct., litter, soil cores, pit-trap. U.S. records: Connecticut, Illinois, Indiana, Iowa, Kansas, Louisiana, Maryland, Massachusetts, Missouri, New York, North Carolina, Ohio, Tennessee, Vermont, West Virginia. Canadian records: Nova Scotia, Ontario.

Entomobrya (Entomobrya) assuta Folsom, 1924. LP, UP, DC, T44N-R29W-S19, 5 Aug.–14 Sept.; T43N-R29W-S8, 19 Aug.–22 Oct.; T44N-R29W-S25, 28 July–6 Oct., litter, pit-trap. U.S. records: Arizona, Connecticut, Florida, Illinois, Indiana, Iowa, Kentucky, Louisiana, Maryland, Massachusetts, Missouri, New York, North Carolina, South Carolina, Texas, Utah, Vermont, Wisconsin. Canadian records: Ontario, Quebec.

Entomobrya (Entomobrya) clitellaria Guthrie, 1903. LP, UP, DC, T44N-R29W-S19, 7 Aug.–7 Oct.; T43N-R29W-S8, 19 Aug., pit-trap. U.S. records: California, Illinois, Indiana, Iowa, Louisiana, Massachusetts, Minnesota, New York, Oregon, Pennsylvania. Canadian records: Ontario, Quebec.

Entomobrya (Entomobrya) comparata Folsom, 1919. T44N-R29W-S19, 6–30 Aug.; T43N-R29W-S8, 3 Aug.–23 Oct.; T43N-R30W-S11, 7 May–15 Oct.; T44N-R29W-S25, 4 June–20 Oct., soil cores, pit-trap. Our specimens are yellow to flesh color with light purple intersegmental lines. Christiansen and Bellinger (1981) reported that this species has so far only been taken from mountainous regions. In the forests of the ELF Project area, this is a dominant species. In color pattern, it comes closest to the mountain tundra form illustrated by Christiansen and Bellinger (1981) (Figs. 12–13). U.S. records: Alaska, California, Colorado, Idaho, Maine, Montana, Nevada, New Hampshire, New Mexico, Washington, Wyoming. Canadian records: Alberta, Northwest Territories.

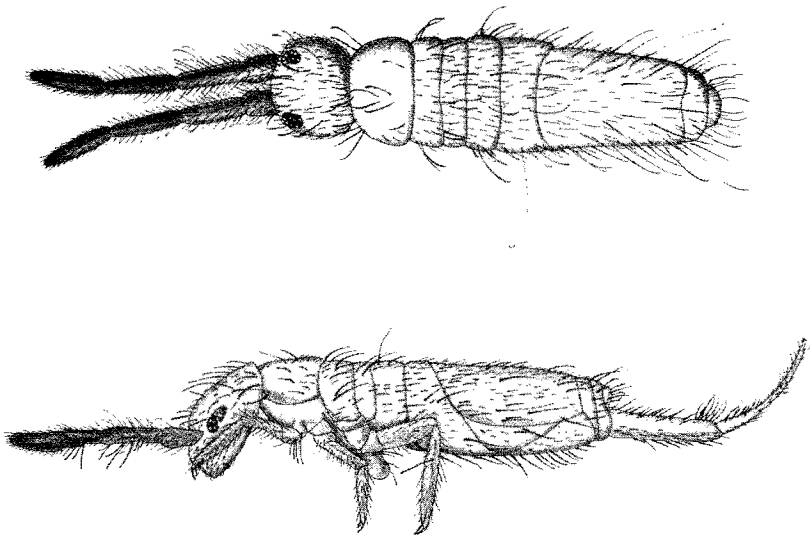
Entomobrya (Entomobrya) nivalis (L.), 1758. LP, UP, DC, T44N-R29W-S19, 16 Sept–4 Oct.; T43N-R30W-S11, 22 May–27 Oct.; T44N-R29W-S25, 10 May–20 Oct. litter, soil cores, pit-trap. U.S. records: Massachusetts, North Carolina, Wisconsin. Canadian records: Ontario.

Entomobrya (Entomobryoides) purpurascens (Packard), 1873. LP, UP, DC, T44N-R29W-S19, 4–5 Aug.; T43N-R30W-S11, 4 June–15 Oct.; T44N-R29W-S25, 5 June–14 Sept., litter, soil core, pit-trap, U.S. and Canadian records: ubiquitous.

Willowsia buski (Lubbock), 1870, LP, UP, DC, T43N-R30W-S11, 30 Aug.; T44N-R29W-S25, 15 Aug.–6 Oct., litter, soil cores, pit-trap. U.S. records: California, Colorado, Connecticut, Illinois, Iowa, Louisiana, Maine, Massachusetts, Minnesota, New York, North Carolina, Utah, Washington, Wisconsin. Canadian records: British Columbia, Manitoba, Ontario, Quebec, Saskatchewan.

Lepidocyrtus helenae Snider, 1967. LP, UP, DC, T44N-R29W-S19, 4–6 Aug.; T43N-R29W-S8, 4 Aug.–27 Oct.; T43N-R30W-S11, 21 May–20 Oct.; T44N-R29W-S25, 29 May–29 Sept., litter, soil cores, pit-trap. U.S. records: Arkansas, Connecticut, Illinois, Indiana, Kentucky, Louisiana, Mississippi, Vermont (Bellinger 1982).

Exhibit 12



Figs. 12–13. *Entomobrya comparata* Folsom. (12) Habitus, lateral view, (13) Habitus, dorsal view.

Lepidocyrtus hirtus Christiansen and Bellinger, 1981. T44N-R29W-S19, 4 Aug., pit-trap. U.S. records: Iowa

Lepidocyrtus lignorum (Fabricius), 1775. LP, UP, DC, T44N-R29W-S19, 5 Aug.; T44N-R29W-S25, 21 May–2 Oct., pit-trap. U.S. records: Arkansas, Connecticut, Illinois, Indiana, Kansas, Louisiana, Tennessee, West Virginia.

Lepidocyrtus paradoxus Uzel, 1891. LP, UP, DC, T44N-R29W-S19, 5 Aug.–5 Oct.; T4 3N-R29W-S8, 10 Aug.–22 Oct.; T4 3N-R30W-S11, 8 May–15 Oct.; T44N-R29W-S25, 25 June–26 Sept., litter, pit-trap. This species was found in large numbers in the basement of our research facility and in a barn where soil samples were processed.

Lepidocyrtus violaceous (Fourcroy), 1785, LP, UP, DC, T44N-R29W-S19, 5–12 Aug., T43N-R30W-S11, 15 May–15 Oct., T44N-R29W-S25, 15 May–4 Sept., litter, soil cores, pit-trap. U.S. records: California, Colorado, Connecticut, Illinois, Indiana, Kentucky, Maine, Massachusetts, New York, Utah. Canadian records: Nova Scotia, Northwest Territories.

Pseudosinella rolfsi Mills, 1932. LP, T43N-R30W-S11, 20–21 Aug.; T44N-R29W-S25, 25 Aug.–14 Sept., litter, pit-trap. U.S. records: Arizona, California, Colorado, Connecticut, Florida, Illinois, Iowa, Louisiana, Massachusetts, New Mexico, New York, North Carolina, Ohio, Pennsylvania, Texas, Utah, Washington, Wisconsin.

Pseudosinella violenta (Folsom). 1924 LP, UP, T43N-R30W-S11, 18–21 Aug.; T44N-R29W-S25, 27 July–20 Oct., soil cores, pit-trap. U.S. records: Arkansas, California, Colorado, Connecticut, Florida, Illinois, Indiana, Iowa, Louisiana, Kentucky, Maryland, Massachusetts, Missouri, New Jersey, New Mexico, New York, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Washington. Canadian records: Nova Scotia, Ontario, Quebec.

Exhibit 12

Subfamily Tomocerinae

Tomocerus (Pogonognathellus) flavescens Tullberg, 1871. LP, UP, DC, T44N-R29W-S19, 4 Aug.–8 Oct.; T43N- R29W-S8, 4 Aug.–29 Oct.; T43N-R30W-S11, 7 May–16 Oct.; T44N- R29W-S25, 8 May–16 Oct., litter, soil cores, pit-trap. A dominant species in the woodlots. U.S. records: ubiquitous.

Tomocerus (Tomocerina) lamelliferus Mills, 1934. LP, UP, DC, T44N-R29W-S19, 4–30 May.; T43N-R30W-S11, 7 May–20 Oct.; T44N-R29W-S25, 28 July–20 Oct., litter, soil cores, pit-trap. U.S. records: east coast, California, Indiana, Washington. Canadian records: Ontario.

Suborder SYMPHYPLEONA
Family NEELIDAE

Neelus (Megalothorax) minimus (Willem), 1900. T43N-R29W-S8, 10 Aug.–22 Oct.; T43N-R30W-S11, 28 July–20 Oct.; T44N-R29W-S25, 28 July–15 Aug., litter, soil cores. U.S. records: Alabama, Alaska, Colorado, (Fjellberg 1984), Connecticut, Florida, Illinois, Indiana, Iowa, Kentucky, Maryland, Massachusetts, Missouri, New York, Tennessee, Utah, Vermont (Bellinger 1982), Virginia, Wisconsin. Canadian records: Alberta, Ellesmere Is., Northwest Territories, Nova Scotia, Quebec.

Neelus (Megalothorax) incertus (Börner), 1903. T43N-R29W-S8, 10 Aug.–4 Oct.; T43N-R30W-S11, 28 July–30 Aug.; T44N-R29W-S25, 28 July–30 Aug., litter, soil cores. We believe this species shows enough variation with *Neelus (Megalothorax) tristani* Denis, 1933 to be the same. U.S. records: California, Illinois, Indiana, Iowa, Kansas, Louisiana, North Carolina, South Carolina, Tennessee. Canadian records: Quebec.

Neelus (Neelides) minutus (Folsom), 1901. LP, T43N-R29W-S8, 10–12 Aug.; T43N-R30W-S11, 28 July–30 Aug., litter, soil cores. U.S. records: Alaska, California, Idaho, Illinois, Indiana, Iowa, Kansas, Maryland, Massachusetts, Mississippi, New York, North Carolina, Tennessee, Utah, Vermont (Bellinger 1982).

Neelus (Neelides) snideri (Bernard), 1975. LP, T43N-R29W-S8, 10 Aug–22 Oct.; T43N-R30W-S11, 3 July., litter, pit-trap. U.S. records: Michigan (type).

Family SMINTHURIDAE
Subfamily Sminthuridinae

Sminthurides (Sphaeridia) pumilis Krausbauer, 1898. LP, T44N-R29W-S25, 17 July, pit-trap. U.S. records: Alaska, California, Colorado, Idaho, Indiana, Iowa, Louisiana, Minnesota, Mississippi, Missouri, Nebraska, New Mexico, New York, Oklahoma, South Carolina, Tennessee, Utah. Canadian records: Manitoba, Northwest Territories.

Sminthurides (Sminthurides) lepus Mills, 1934. LP, UP, DC, T44N-R29W-S19, 3 Aug.–8 Oct.; T43N-R29W-S8, 10 Aug.–4 Oct.; T43N-R30W-S11, 7 May–20 Oct.; T44N-R29W-S25, 21 May–16 Oct.; litter, soil cores, pit-trap. This is one of the most numerous species to be found in the ELF Project area. U.S. records: Connecticut, Illinois, Indiana, Iowa, Louisiana, Maryland, New York, North Carolina, South Carolina, Vermont (Bellinger 1982). Canadian records: Ontario.

Sminthurides (Sminthurides) occultus Mills, 1934. LP, UP, DC, T44N-R29W-S25, 16 July, pit-trap. U.S. records: California, Illinois, Indiana, Iowa, New York, North Carolina, South Carolina, Tennessee. Canadian records: Manitoba, Northwest Territories, Ontario.

Exhibit 12

Subfamily Katianninae

Arrhopalites amarus Christiansen, 1966. UP, DC, T44N-R29W-S19, 4 Aug.–8 Oct.; T43N-R29W-S8, 3 Aug.–4 Oct.; T43N-R30W-S11, 15–30 Aug.; T44N-R29W-S25, 28 July–20 Oct., litter, pit-trap. U.S. records: California, Colorado (Fjellberg 1984), Connecticut, Illinois. Canadian records: Labrador, Ontario.

Arrhopalites benitus (Folsom) 1896. LP, UP, DC, T44N-R29W-S19, 4 Aug.–8 Oct.; T43N-R29W-S8, 7–9 Sept.; T43N-R30W-S11, 7 May–16 Oct.; T44N-R29W- S25, 11 June–20 Oct., litter, soil cores, pit-trap. U.S. records: Illinois, Massachusetts, North Carolina, Oregon, South Dakota, Virginia, West Virginia, Wisconsin.

Arrhopalites caecus (Tullberg), 1871. LP, UP, DC, T43N-R30W-S11, 28 July–4 Sept., soil cores, pit-trap. U.S. records: California, Colorado, Illinois, Indiana, Iowa, Massachusetts, Minnesota, New York, North Carolina, South Dakota, Tennessee, Utah, Wisconsin. Canadian records: Alberta.

Sminthurinus (Katiannina) macgillivrayi (Banks), 1897. LP, UP, T43N-R29W-S8, 29 Sept.; T43N-R30W-S11, 7 May–12 June.; T44N-R29W-S25, 15 May–26 June., pit-trap. U.S. records: Illinois, Indiana, Kentucky, Maryland, Missouri, New York, North Carolina, Pennsylvania, Tennessee, Vermont (Bellinger 1982) Canadian records: Ontario.

Sminthurinus (Polykatianna) intermedius Snider, 1978. UP, DC, T44N-R29W-S19, 7 Aug.–6 Oct., pit-trap. U.S. records: Connecticut, Illinois, Indiana, Iowa, Maryland.

Sminthurinus (Sminthurinus) conchyliatus Snider, 1978. UP, DC, T44N-R29W-S19, 7 Aug.–6 Oct., pit-trap. U.S. records: Illinois.

Sminthurinus (Sminthurinus) henshawi (Folsom), 1906. LP, UP, DC, T44N-R29W-S19, 3 Aug.–8 Oct.; T43N-R29W-S8, 4 Aug.–29 Oct.; T43N-R30W-S11, 15 May–27 Oct.; T44N-R29W-S25, 21 May–27 Oct., litter, pit-trap. This is a very common species in our woodlots. U.S. records: ubiquitous.

Sminthurinus (Sminthurinus) quadrimaculatus (Ryder), 1879. LP, UP, DC, T44N-R29W-S19, 4 Aug.–7 Oct.; T43N-R29W-S8, 2 Sept.; T43N-R30W-S11, 5 July–4 Sept.; T44N-R29W-S25, 14 May–2 Oct., pit-trap. The two-spotted form occurs in the woodlots. U.S. records: California, Colorado (Fjellberg 1984), Connecticut, District of Columbia, Florida, Illinois, Indiana, Iowa, Kentucky, Louisiana, Maine, Maryland, Massachusetts, Minnesota, New York, North Carolina, Pennsylvania, Tennessee, Wyoming. Canadian records: New Brunswick, Quebec, Ungava Bay.

Subfamily Sminthurinae

Bourletiella (Bourletiella) hortensis (Fitch), 1868. LP, UP, DC, T44N-R29W-S19, 30 Aug.; T43N-R29W-S8, 10 Aug.–4 Oct.; T43N-R30W-S11, 11–12 June, litter, pit-trap. U.S. records: ubiquitous.

Bourletiella (Deuterosminthurus) russata Maynard, 1951, LP, UP, T43N-R30W-S11, 5 June–3 July.; T44N-R29W-S25, 17 July, pit-trap. U.S. records: Illinois, Indiana, Iowa, New York, Utah.

Bourletiella (Heterosminthurus) koontzi, **n.sp.** (Figs. 14–46)

During the summer of 1984, sminthurids were collected in Dickinson County, Michigan (T43N-R30W-S8). The specimens were taken in a field by using a white enamel pan for sweeping grass and shrubs. It was a sunny, windy day with a temperature of approximately 24°C.

COLOR AND PATTERN (female): (Figs. 14–15). Background faint yellow. Antennae uniformly purple. Head with olive green mosaics forming two lines originating from behind the head and extending to approximately the posterior edge of the

Exhibit 12

eyepatches. Frons with light patches of green. Thorax with light green paramedial broken lines. Lateral olive green mosaics originating on the third thoracic segment converging with the paramedial lines on the greater abdomen; fifth abdominal segment with dark green bands on the posterior margins; abdominal segment VI with two black maculae. Bothriotricha A.B.C surrounded by black pigment. Venter, legs, furcula colorless.

HEAD: eyes 8 + 8 with dark pigment; ocelli A and H subequal (Fig. 16). Antennal segment ratio 1:2:3:7; ANT IV with 9 subsegments, apical bulb (Fig. 17), subsegments with or without fine setulae in the following distribution: II, III, VII, VIII, IX with none, I-1, IV-2, V-2, VI-1 (Fig. 18) with sense organ with two blunt setae withdrawn into a pit with accessory seta (Fig. 19). Dorsum of head with 4 spine-like setae (Fig. 20).

FORELEG: coxa with 1 seta and no oval organs (Fig. 21); trochanter with 1 anterior and 2 posterior setae and no oval organs (Fig. 22); femur with 7 anterior and 8 posterior setae and one oval organ (Fig. 23); anterior and posterior surface with 3 oval organs (Figs. 24–25); tibiotarsus with 3 strongly clavate tenent hairs; pretarsus with posterior curving setulae; unguis curving—lanceolate with no inner or outer teeth, without tunica; unguiculus lanceolate, without lamella, with long strong apical filament (Fig. 26).

MESOLEG: coxa with 2 setae and 1 oval organ (Fig. 27); trochanter with 5 anterior setae and 1 posterior seta, with 1 oval organ (Fig. 28); femur with 1 oval organ, 12 anterior and 4 posterior setae (Fig. 29); anterior and posterior surface of tibiotarsus with 3 oval organs (Figs. 30–31); tibiotarsus with 3 strongly clavate tenent hairs; unguis similar to forefoot; unguiculus with large basal lamella, apical filament stout, pointed.

METALEG: coxa with 4 setae and 1 oval organ (Fig. 32); trochanter with 1 oval organ, 5 anterior and 1 posterior setae (Fig. 33); femur with 1 oval organ, 10 anterior and 5 posterior setae (Fig. 34); anterior and posterior surface of tibotarsus with 3 oval organs (Figs. 37–38); tibiotarsus with 2 strongly clavate tenent hairs; pretarsus with anterior curving setulae; unguis curving, lanceolate; unguiculus with large basal lamella, apical filament stout and pointed (Fig. 35). NOTE: oval organs are reported, but we suspect others will be found.

BODY: Collophore with 1 + 1 subapical setae (Fig. 39). Tenaculum with 3 setulae, ramus with 2 teeth (Fig. 36). Manubrium with 8 + 8 dorsal setae (Fig. 40). Dens ventrally with 5 V_e setae and 3 V_{e2} dens dorsally with 9 E setae, 7 ID setae, 7 L setae (Figs. 44–45). Mucro with external margin weakly crenulate, internal margin smooth (Figs. 41–42). Female subanal appendage acuminate (Fig. 43). Bothriotrichia A, B, C, D. Body setae smooth. Length, 0.75 mm.

DIAGNOSIS: *Bourletiella (Heterosminthurus) koontzi* n.sp. keys out nearest to *Bourletiella (Heterosminthurus) dreisbachi* (Snider) in Christiansen and Bellinger (1981). However, besides morphological characteristics, color pattern will separate the two species. The following will distinguish the species:

B. (H.) koontzi	*B. (H.) dreisbachi*
Dorsum of head with 4 spine-like setae	no spine-like setae
ocelli A and H subequal, others reduced in diameter	ocelli C and H subequal others subequal
metaunguiculus with lamella tapering	lamella rounded

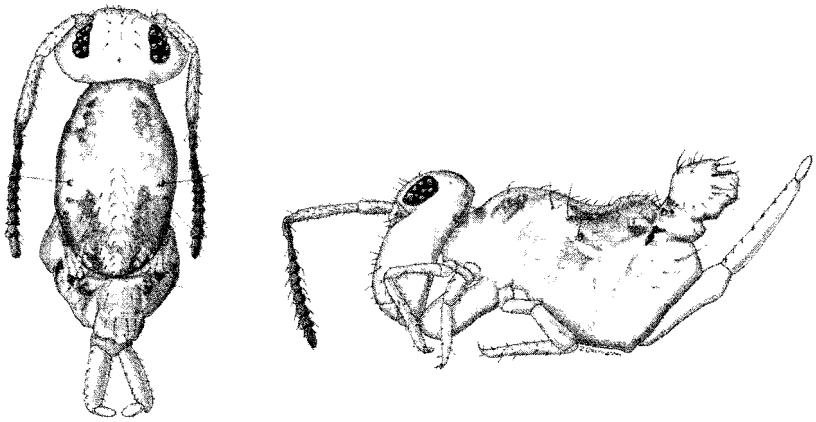
TYPES: Holotype (female), allotype (male) and 50 paratypes in ethanol; three females and three males on slides. All types deposited in the Entomology Museum, Michigan State University.

Collection data: Michigan, Dickinson county T43N-R30W-S8, sweeping shrubs in field, 18-VI-84 and 24-VI-84, F.J. Calandrino, collector.

We take pleasure in naming this species for Captain Ronald L. Koontz, Program Manager, ELF Communication System, Department of the Navy Space and Naval Warfare Systems Command.

Neosminthurus bakeri Snider, 1978. T44N-R29W-S25, 18 June, pit-trap. This is the northern-most range so far recorded for this species. U.S. records: Kentucky, North Carolina. Tennessee.

Exhibit 12



Figs. 14–15. *Bourletiella (Heterosminthurus) koontzi*, n.sp. (14) Habitus, dorsal view, (15) Habitus, lateral view.

Sminthurus (Sminthurus) butcheri Snider, 1969. LP, UP, DC, T44N-R29W-S19, 3 Aug.; T43N-R29W-S8, 4 Aug.–9 Sept.; T43N-R30W-S11, 17 July, litter, pit-trap. U.S. records: Connecticut, Louisiana, Utah.

Sminthurus (Sminthurus) nigromaculatus Tullberg, 1871. T43N-R30W-S8, 27 July–16 Sept., grass sweeping. This species has been in doubt until recently. Its color pattern (Figs. 47–48) is similar to *Sminthurus viridis* (L.) and the two are frequently confused. Hammer (1953) reported *S. viridis* from Canada. Examination of her slides revealed that the specimens were *S. nigromaculatus*. The two species appear to occupy the same range in Europe, however only *S. nigromaculatus* ranges into North America. *S. viridis* feeds on plant fluids while *S. nigromaculatus* gut contents contain hyphae and spores. Morphological separation is possible by examination of the collophore; *S. viridis* lacks a pair of lateral setulae. For a discussion of population variation and habitat descriptions, see Wallace (1973). Canadian records: Northwest Territories.

Sminthurus (Allacma) purpurescens (MacGillivray), 1894. T43N-R30W-S11, 16–17 July, pit-traps. The specimens reported here are patterned with white not frequently seen in published illustrations (Figs. 49–50). U.S. records: Massachusetts, Minnesota, New York, North Carolina, Tennessee. Canadian records: Newfoundland.

Subfamily Dicyrtominae

Dicyrtoma (Dicyrtoma) aurata (Mills), 1934. T43N-R30W-S11, 7 May–16 Oct.; T44N-R29W-S11, 7 May–16 Oct.; T44N-R29W-S25, 3–29 Sept., pit-trap. U.S. records: Iowa, North Carolina.

Dicyrtoma (Ptenothrix) atra (L.), 1758. LP, UP, DC, T43N-R30W-S11, 25 Aug., pit-trap. Exhibit 12

PUDDLING BY FEMALE FLORIDA TIGER SWALLOWTAIL BUTTERFLIES, *PAPILIO GLAUCUS AUSTRALIS* (LEPIDOPTERA: PAPILIONIDAE)

J. Mark Scriber [1]

Many species from all families of Rhopalocera have been reported to drink water (Norris 1936). Bates (1863) noted that, in the Amazon, 80 species from 22 genera flocked about the damp edges of water and, with very few exceptions, all of these individuals were males. Adler (1982) reported that of 3417 known individuals of night-puddling moths (representing 93 genera from 10 families), 1.3% were represented by female individuals from only 16 species. A distinction between "puddle-butterflies" (which assemble together at puddles) and "roadside-butterflies" (which are often seen drinking, but not in groups) was made by Clark (1932). This individual puddling has been described by Berger and Lederhouse (1985).

Assemblages of butterflies have also been reported on dung, urine, perspiration, saliva, salt, blood, campfire ashes, aphid honeydew, tree sap, and animal carrion (Scudder 1889, Norris 1936, Sevastopulo 1974, Downes 1973, Adler 1982). Aggregation of butterflies is often catalyzed by the use of dead specimens or yellow "decoy" substrates (Denton 1889, Clark 1932), and these have been successfully used in puddling experiments with the eastern tiger swallowtail butterfly, *Papilio glaucus* L. (Arms et al. 1974). While the choice of the puddling spot by the initial male butterfly may be made largely by chemical attraction (Couper 1873, Norris 1936), it has been shown that duration of puddling behavior is extended on moist sand containing sodium ions regardless of the anion present (Arms et al. 1974). Furthermore, while male tiger swallowtail butterflies ingest amino acids during puddling, Arms et al. (1974) concluded that ingestion of amino acids is less likely to be the major function of puddling than is ingestion of sodium. Adler and Pearson (1982) postulated that the reduction of sodium in male butterflies may be a consequence of mating (spermatophore transfers). Why sodium would be significantly more important for male butterflies than females has not been entirely resolved because females are known to lose up to 75% of their sodium via oviposition (Adler and Pearson 1982). Moreover, it has not been resolved to what degree female tiger swallowtail butterflies actually engage in such "puddling" behavior.

To my knowledge, no published records existed until recently (Berger and Lederhouse 1985) of puddling by females of any populations of *Papilio glaucus*. No females were observed puddling at any time during the Arms et al. (1974) study, nor have I observed any female of *P. glaucus glaucus* L. or *P. glaucus canadensis* Rothschild & Jordan amongst the hundreds (probably several thousand) of puddling males I have seen in the subsequent nine years (Scriber and Lintereur 1983, Lederhouse 1982, Wagner 1978). My recent observations of single puddling females of *P. glaucus australis* Maynard in Highlands County, Florida, during 1–4 August 1983, are here reported.

I observed four different *Papilio glaucus australis* females individually engaged in brief, but definite, puddling behavior. These observations ranged from 10 to 25 sec in duration. Three of these females were of the yellow morph phenotype and one was a dark morph (Scriber et al., in press). On 2 August 1983, each of the three yellow females was first observed in slow gliding flight along the sand and muck drainage ditches adjacent to

Exhibit 12

Hall Road and route 29 S, near the McClellan Bulb Farm south of Lake Placid, Florida (Highlands County). At 1136, 1146, and 1626 h, each of these single females alighted on the ground and began to probe the moist soil with its extended proboscis. The dark morph female was observed slowly flying over the muck field and at 1345 h alighted on the muck soil and probed about with its proboscis on a moist clod of muck. All four females were eventually captured and are currently preserved in our *Papilio* research collection at Michigan State University. No additional puddling observations of any type were made during the following two days of continuous collecting, perhaps because the ground had dried considerably and insignificant rainfall had occurred compared to that which occurred on 1 August. The total numbers of captures for females and males of *P. glaucus* at this site were not significantly different during 2 August (23 males, 4 dark morph females, 13 yellow morph females) and 3 August (20 males, 1 dark and 10 yellow females). No male *P. glaucus* butterflies were observed puddling at any time. One perfect (apparently newly eclosed) *Papilio troilus* L. male was observed to settle on the sandy road to probe on the morning of 4 August 1983.

The question of why puddling behavior in female butterflies is rare as has been assumed, has not been adequately resolved. Perhaps it is not really as rare as generally believed. Among the various explanations of the scarcity of female puddling observations could be the apparently brief duration of the behavior (less than 30 sec) relative to that for males. Hundreds of male *P. glaucus* may sit in dense aggregations for extended periods of time (Couper 1873, Scudder 1889). It is also possible that the females never aggregate as do males, and therefore the individual behavior is much less obvious in the case of females. Thirdly, the time and (or) location of puddling behavior may be generally different than males. For example, it is generally the newly eclosed (i.e. very fresh looking) males which predominate (almost to exclusion) in any puddling aggregation (Lederhouse 1982), whereas two of the females I observed in Florida were obviously worn and likely to be many days old. Similarly, a single female *Papilio polyxenes* Fabricius observed puddling in 1973, in New York State, was extremely worn. Finally, the specific reasons for puddling behavior remain uncertain, and it is possible that these are very different in magnitude and (or) type for female than for male Lepidoptera (e.g. mate location). Berger and Lederhouse (1985) have suggested that individual puddling behavior by females may be to avoid harassment by males.

The degree to which females of the different subspecies of the *Papilio glaucus* complex engage in puddling behavior may be of ecological interest, but must await further study. This report of female puddling represents the first for *P. g. australis*; that of Berger and Lederhouse (1985) represented the first for New York *P. glaucus* (*P. g. glaucus* or *P. glaucus canadensis*). New York is a likely hybrid zone for these two subspecies (Scriber 1982, Ritland and Scriber 1985). The suggestion that introgressive hybridization might account for the origin of puddling behavior in some Lepidoptera has been made (Clark and Clark 1951), but still needs additional study (Shapiro 1979).

APPEARANCE OF DAMAGE SYMPTOMS AND REINFESTATION RATES FOR CHRISTMAS TREES ATTACKED BY THE ZIMMERMAN PINE MOTH, *DIORYCTRIA ZIMMERMANI* (LEPIDOPTERA: PYRALIDAE)[1]

James W. Yonker and Donald L. Schuder[2]

ABSTRACT

Two blocks of Scotch pine Christmas trees were inspected to determine an appropriate time to evaluate Zimmerman pine moth damage, and to determine reinfestation rates for trees previously attacked by this insect. Results showed that damage evaluation should be delayed until mid-August and possibly later, in early fall. Evaluation done before this time could result in underestimation of total damage. In the reinfestation study, previously attacked trees were shown to sustain both a higher rate of reattack and more attacks per tree the following year than control trees. However, at most, only 61% of the new attacks the following year were on trees with a previous attack. Also, 47% or more of the infested trees observed the second year were newly infested. These results indicate little practical benefit of using attacked trees solely as a trap crop for ovipositing moths. Attacked trees with severe damage should therefore be removed.

The Zimmerman pine moth (ZPM), *Dioryctria zimmermani* (Grote), is a primary pest of Christmas trees grown in the Midwest (Rennels 1960, Schuder 1960, Butcher and Carlson 1962). Its preferred host is Scotch pine, *Pinus sylvestris* (L.), but it does attack all *Pinus* spp. grown in the Great Lakes region (Schuder 1960; Yonker 1982). The damage it causes can be aesthetic and monetary, as broken terminals, dead laterals, and altered tree-form can all result from attack.

Carlson (1965) developed regression relationships for infested whorls and terminals to predict the extent of an infestation on a plantation-wide basis. However, an attempt to correlate the number of damaged lateral branches with the total number of infested trees in a field was not successful. Also, timing of tree inspections with respect to appearance of damage was not established. In the current study, individual trees were inspected to determine when initial damage appears, and when maximum damage is sustained. Results of this study should help growers evaluate the full extent of damage in their fields, and aid them in making control decisions.

Several authors have outlined chemical control programs (Butcher and Carlson 1962, Appleby and Randell 1980, Schuder 1983), including recommendations for removing heavily infested, damaged trees (Rennels 1960, Schuder 1960). These latter authors stated that once a tree is attacked, it is often reattacked in following years and serves as a source of infestation for other trees. This relationship was further studied, with emphasis on the feasibility of using attacked trees as a natural trap crop for ovipositing females.

B (1980)	371	53 (14.3)	17 (4.6)	32.1[a]

[a]Due to harvest, damage estimate was based upon an August, not November evaluation.

MATERIALS AND METHODS

Two blocks of Scotch pine Christmas trees located in Rochester, Indiana, were chosen for study. The presence of ZPM in 1978 and the minimal use of insecticides prior to this study were two criteria for block selection. In 1979, trees in block A were 4 years old, with heights ranging from 0.9 to 1.2 m. Trees in block B were 6 years old, with heights from 1.8 to 2.4 m. Both blocks were surrounded by other blocks of trees in this 8.1-ha field.

Each tree was initially examined for ZPM attacks in late June. Both the number and location of all attacks was carefully noted, as well as the appearance of all visible damage. Damage included broken or dead terminal and lateral leaders, and dead lateral branches. Trees with attacks were reinspected in mid-July, August, and November to document later occurring damage. The November inspection was chosen to ascertain final (recognizable) damage before the occurrence of fall needle yellowing and drop that could disguise damage. From the inspections, initial and maximum damage were determined, as well as infestation rates for previously attacked and unattacked trees.

RESULTS

Table 1 describes the infestation rates and damage characteristics of blocks A and B. During the study, an average of 11.8 and 14.8% of the trees sustained at least one ZPM attack in blocks A and B, respectively. Approximately 48% of the attacked trees from both blocks showed some degree of damage. One or more dead lateral branches extending from an infested whorl area was the most common damage observed. Dead terminal or secondary leaders resulting from attack(s) in the top whorl were less common. ZPM tunneled leaders were rarely observed.

Figure 1 shows the chronological appearance of all ZPM damage observed. For both blocks, the percentage of trees ultimately damaged that showed damage in June was less than 15%. Through July and early August, damage increased substantially, but began to level-off by mid-August. Damage occurred earlier in block A and may be related to the smaller tree's inability to tolerate ZPM attacks. Only 6–14% of the total damage observed occurred after mid August.

Data collected from trees with old and current attacks were used to determine reinfestation rates for trees in both blocks. Reinfestation rates were compared to rates of attack for trees not attacked the first year, but attacked the second year (control trees). Table 2 shows that for each study year, trees with an attack were much more prone to attack the following year than the control trees ($P < 0.05$, χ^2 analysis in 2×2 contingency table). Also, these trees sustained significantly ($P < 0.05$) more attacks per

Exhibit 12

Table 3. Efficiency of ZPM-infested trees as a trap crop for ovipositing ZPM moths.

Block (Year)	No. Trap Crop Trees	% New Attacks on Trap Crop[a]	No. Newly Infested Trees	% Infested Trees Newly Infested
A (1978)	16	18 (0)	53	84
A (1979)	63	31 (8)	105	76
A (1980)	138	56 (27)	93	53
B (1978)	109	61 (34)	71	47

[a]Number in parentheses is the percentage of attacks on trap crop trees with two or more current attacks.

tree the following year than the control trees. These results imply either a moth attraction for previously attacked trees, some degree of restriction of ovipositing moths to trees from which they emerged, or a higher larval survival rate on the attacked trees.

Table 3 shows the potential of using ZPM infested trees as a natural trap crop for ovipositing females. In the best years, infested trees "caught" only 61 and 56% of the following years' attacks. Even then, 47–53% of all trees attacked the second year were newly infested. Table 3 also shows the protection afforded by those trap crop trees with at least two active attacks. These trees caught, at most, 34 and 27% of the attacks observed the following year.

DISCUSSION

The damage evaluation study showed that a time lag of at least three months exists between ZPM attack (mid-April) and the appearance of substantial damage (late July). These results suggest that the most accurate time to assess damage is after mid-August. Growers who evaluate damage earlier, for instance at shearing (June), may severely underestimate total damage. Evaluation done at moth emergence (early to mid-August) provides a better estimate, and also allows for the application of an insecticide at a time when ZPM is susceptible.

Although most damage, even that appearing in June, was still evident in November, its cause (ZPM, other insect, or mechanical) was sometimes not discernible in November. This suggests that growers should still make evaluations in late summer or early fall to help distinguish all ZPM damage. Damage evaluation at this time is also practical for growers who prefer a spring (April) insecticide application (Appleby and Randell 1980).

The reinfestation results showed that although the infested trees sustained a higher rate of reattack than the control trees, many newly infested trees were observed the following year. Attacked trees, particularly those most heavily infested, did not provide adequate protection for the previously uninfested trees. Since a trap crop does not seem feasible, the recommendation to remove the heavily infested, unsellable trees seems justified (Rennels 1960, Schuder 1960). Also, chemical protection should still be considered for all trees to prevent the current infestation from spreading away from the attacked trees left in the plantation.

Exhibit 12

AN IMPROVED BIOTIC INDEX OF ORGANIC STREAM POLLUTION[1]

William L. Hilsenhoff[2]

ABSTRACT

Major improvements were made in using a biotic index of the arthropod fauna to evaluate organic stream pollution. All tolerance values were reevaluated, many were changed, and the scale for tolerance values was expanded to 0–10 to provide greater precision. Keys to larvae of *Ceratopsyche* have been developed and tolerance values for species in this important genus are provided. Sorting of samples in the laboratory instead of in the field is recommended, and directions for processing and evaluating samples are included.

A "saprobic index" (Pantel and Buck 1955) and a "biotic index" (Chutter 1972) were proposed for evaluating the water quality of streams through a study of their fauna. I introduced a similar biotic index (Hilsenhoff 1977) that used only arthropods for evaluation, thus simplifying collecting, sorting, and identification. It was based on a sample of 100 or more arthropods collected from a riffle area. This index is a measure of organic and nutrient pollution, which causes lower dissolved oxygen levels, especially at night during the summer and after heavy rain. Lowered levels of dissolved oxygen in turn affect the ability of each species of arthropod to survive in a particular stream. For the purpose of calculating the biotic index, every species or genus was assigned a tolerance value of 0–5, with 0 assigned to species most intolerant of organic pollution and 5 assigned to the most tolerant species. Intermediate values were assigned to species intermediate in their tolerance of organic pollution. The biotic index is an average of tolerance values for all individuals collected from a site.

Initially the index was used mostly in Wisconsin. In 1979 and 1980 the Wisconsin Department of Natural Resources (DNR), in cooperation with the University of Wisconsin, used the index to evaluate more than 1000 stream sites in spring and autumn. Personnel in my laboratory identified all the arthropods and calculated biotic index values for all sites. Experience from this cooperative study and several other studies enabled me to publish new recommendations for using the biotic index, revised tolerance values, and regional keys to species in important genera (Hilsenhoff 1982).

Recently, additional improvements have been made in the biotic index. Most important are an expansion of the scale of tolerance values to 0–10 to provide greater precision, a reevaluation of all tolerance values, and inclusion of tolerance values for many additional species. Procedures for sampling and sorting were updated, and a discovery that *Simulium vittatum* is really two genetically distinct species (Rothfels and Featherston 1981) with differing ecological requirements (Adler and Kim 1984) altered my recommendation for dealing with these sibling species. Adequate correction factors for current, temperature,

Exhibit 12

and seasonal differences are needed, and studies to correct these deficiencies will be completed soon.

REASSIGNMENT OF TOLERANCE VALUES

Initial tolerance values for each species were based mostly on a study of 53 Wisconsin streams in which physical and chemical parameters were evaluated to determine the degree of organic and nutrient pollution in each stream (Hilsenhoff 1977). Tolerance values for species not found or occurring rarely in these streams were based on their occurrence in other streams and their association with species to which tolerance values had been asigned.

Data from more than 2000 samples collected in the 1979–80 cooperative study with the DNR were used to reevaluate tolerance values by comparing the tolerance value of each species with the average biotic index value of streams in which that species most commonly occurred. A description of the procedure that was used can be obtained from the author. It became apparent that intermediate values would increase precision, so the 0–5 scale of tolerance values was expanded to 0–10 to accommodate intermediate values while retaining whole numbers for ease in making calculations. New tolerance values assigned to 359 species or genera found in the DNR samples are listed in Appendix 1.

Forty-nine additional species that were not collected from the 1979–80 study streams, mostly because their life cycles precluded their being present in spring or fall samples, were assigned tolerance values based on our knowledge of streams in which they occurred. Previous experience was also used to adjust tolerance values of nine species that were found in less than five samples from the study streams, and subsequent experience resulted in adjusting values of *Asellus, Crangonyx* and *Hyallela.*

IDENTIFICATION

Accurate identification of arthropods to species is often necessary, especially when a species is numerous in a stream and thus greatly influences calculation of the biotic index. Tolerance values marked with an asterisk (Appendix 1) are least reliable, but the species involved are uncommon in stream riffles and rarely exert much influence on the biotic index. Generic identifications are used only when species identifications are not possible or very difficult, or when in a region all known species in a genus have the same tolerance value. Merritt and Cummins (1984) included keys to North American genera and also referenced regional generic keys, which are easier to use. Hilsenhoff (1981) provided a regional key to genera and references to species keys, which are widely scattered in the literature. Brigham, Brigham and Gnilka (1982) contained regional species as well as generic keys, and Merritt and Cummins (1984) listed species keys, regional keys, and other taxonomic references published through 1982. Recent species keys and identification problems as they relate to the biotic index are discussed below for each order.

PLECOPTERA. Mature nymphs of *Acroneuria, Allocapnia, Pteronarcys,* and *Taeniopteryx* can be identified, but there is a degree of uncertainty in many identifications, especially when nymphs are immature. Because in these genera all species in the western Great Lakes region appear to have similar tolerance values, only a generic tolerance value is used. *Perlesta placida* may be a species complex, with one or more of the species being much less tolerant of organic pollution.

EPHEMEROPTERA. Identification of mayfly nymphs in many genera is not possible, and in other genera species identification must be regarded as somewhat tentative. McCafferty (1975) keyed species of Ephemeridae Polymitarcyidae, and Potamanthidae, but separation of nymphs in these families is not always possible. Since they are relatively uncommon in riffle samples, and because species within each genus appear to have similar tolerance values, only generic tolerance values have been assigned. A recent key by Kondratieff and Voshell (1984) identified nymphs of *Isonychia,* but separation of

Exhibit 12

species requires mature nymphs and is difficult. Only a generic tolerance value was provided for this genus, and it may be too low for one or more of the species. *Ephemerella* species A (Hilsenhoff 1982), which occurs in western Wisconsin, is probably *E. inermis* or a sibling species of that species. Reared adults most closely fit the description of *E. inermis*, as do dark-colored nymphs. *Pseudocloeon* species A (Hilsenhoff 1982) may be a new species, or a species for which nymphs have not been described. Arwin Provonsha at Purdue University has revised the genus *Caenis* and developed keys to the nymphs, which he will publish soon. Identification of *Caenis* nymphs is difficult, and because the three riffle species all have similar tolerance values, only a generic value is included.

ODONATA: Several Odonata that were assigned tolerance values are essentially lentic and occur only occasionally in streams and rarely in riffles. Only nine species or genera were found in 10 or more of the 1979–80 study streams. They rarely made up more than 10% of a sample, so this order is usually not important to biotic index values. Generic tolerance values are used for uncommon genera when species identification is difficult. Only mature nymphs of *Ophiogomphus* can be identified to species (Walker 1958, Needham and Westfall 1955), so a generic tolerance value is also used for this important genus.

TRICHOPTERA: Species identification of larvae in this important order is often difficult or impossible. Recent studies of larvae of Brachycentridae (Chapin 1978, Flint 1984) and Hydropsychidae (Schuster and Etnier 1978, Schefter and Wiggins 1986) and regional keys to most species in these families (Hilsenhoff 1985, Schmude and Hilsenhoff 1986) permitted assignment of tolerance values for many species of these important families. Unfortunately larvae of *Cheumatopsyche* cannot be identified, and apparently relatively intolerant as well as tolerant species exist.

COLEOPTERA: Elmidae adults were observed crawling out of an artificial stream when dissolved oxygen levels become too low, so their value as indicator organisms may be questioned, but larvae probably do not react in the same manner. The genus *Stenelmis* is being revised, and several undescribed species exist. However, almost all adults, and probably larvae also, that were collected from riffles in Wisconsin streams were *S. crenata*. The tolerance value for this species is 5, and that value has been assigned to the entire genus because there is no indication that other species have significantly different tolerance values. Larvae of *Optioservus* and *Dubiraphia* cannot be identified to species so generic tolerance values are used.

DIPTERA: Identification of larvae to species is usually not possible, and sometimes even genera cannot be separated. Larvae of Simuliidae are often common, and well illustrated keys to Canadian species have been published (Wood et al. 1963, Peterson 1970), but their identification is difficult. Pigmentation of the head is variable within the same population, and pupal respiratory filaments must be dissected from mature larvae to identify some species. Furthermore, several species are complexes of genetically distinct species that cannot be separated by morphological characters as was discovered for *Simulium vittatum* (Rothfels and Featherston 1981). Fortunately many species occur on macrophytes or in deeper water and are unlikely to be collected from riffles. Efforts were also made to distinguish species groups within several genera of Chironomidae, but much more work is needed on this important family and tolerance values for Chironomidae have been assigned only to genera. Recent keys separate *Tribelos* from *Endochironomus* and *Phaenopsectra* (Simpson and Bode 1980), *Tvetenia* from *Eukiefferiella* (Bode 1983), and *Xylotopus par* from *Brillia* (Oliver 1982).

COLLECTION AND EVALUATION OF SAMPLES

Organic stream pollution is evaluated by calculating biotic index values for arthropod communities that inhabit rock or gravel riffles. Samples from pools or under the banks of streams should not be used. Arthropods that inhabit riffles are found on rocks and pebbles or in sand and gravel associated with the riffle, and especially in organic debris that

Exhibit 12

accumulates between rocks and pebbles. In deeper streams that have no riffles, samples from rock or gravel runs may be substituted, and in sand-bottomed streams samples of debris that collects on sticks or other objects wedged into the sand in swift current may be used. Slow flowing, silt-bottomed streams presently cannot be evaluated with the biotic index. The season of the year affects the biotic index, with much higher biotic index values often being recorded during the summer months. Results from the first year of a study to develop seasonal correction factors suggest that evaluation may not be possible in the summer months, and that streams should be evaluated from samples collected in the spring before 1 June or after 1 September and before 15 October in the autumn. Samples collected from organically enriched or polluted streams tend to have distinctly higher biotic index values after mid-October and very much higher values in the summer.

In 1982 I recommended a procedure for collecting and sorting samples that involved picking 100+ live arthropods from a sample in the field and included an alternative procedure for picking samples in the laboratory. Experience since that time suggests that many more streams can be sampled in a given period of time if valuable field time is not used to pick the samples. The greatest difficulty in collecting samples for processing in the laboratory was in knowing when an adequate sample had been collected. Our experience with several hundred samples from six diverse streams suggests that when there is enough debris in the sample to fill an 8-ounce (237-ml) jar there will be enough arthropods, and such a sample takes less than 5 minutes to collect. Revised procedures for collecting, sorting, and evaluating samples with the biotic index follow.

1. Use an aquatic net to sample a site where the current is greater than 0.30 m/sec (1.0 ft/sec) and the substrate is composed of gravel, pebbles, and (or) small rocks. This should preferably be a riffle area where the substrate causes a disturbance of the water's surface. All riffle areas with a depth of at least 10 cm will have a current of at least 0.30 m/sec. In sand-bottomed streams, sample debris collected on snags in fast current. Collection of arthropods is best accomplished by placing the net against the stream bottom and disturbing the substrate immediately upstream from the net with your feet. In very fast currents avoid having the net so close to your feet that gravel and pebbles are washed into it. Avoid collecting from rooted macrophytes and filamentous algae.
2. Collect until there is enough debris in the net to fill an 8- ounce (237 ml) jar, or until it is obvious that more than 100 arthropods have been captured. Remove sticks and large undecomposed leaves from the rest of the debris, washing arthropods from them by rinsing in the net in a pool area.
3. Place the arthropods along with all debris in a labeled jar and add enough 95% ethanol to produce a concentration of about 70% when mixed with the water in the debris. Include all arthropods clinging to the net that are 3 mm long and all adult Elmidae.
4. After returning to the labortory, or if in the field for more than a day, sample jars completely filled with debris should be drained of ethanol by pouring through a screen or net with a 1.0 mm or smaller mesh. The ethanol should then be replaced with 70% ethanol. An alternative is to refrigerate the samples to allow ample time for diffusion of the ethanol throughout the debris and into the arthropods.
5. About 15 minutes before picking and sorting a sample in the laboratory, strain the ethanol from the sample and replace it with water. No arthropods should remain floating on the surface of the water.
6. Place the contents of the jar in a large, flat pan marked with a grid, add two or three additional jars full of water, and spread the contents evenly over the bottom of the pan. If the jar is completely filled with fine debris, especially filamentous algae, only half of the sample should be initially placed in the pan for sorting, with care being taken to assure that each half of the sample contains the same amount and kinds of debris. A 30 by 45-cm pan with a 5-cm grid is satisfactory. Larger pans allow the debris to be spread more thinly, making it easier to see the arthropods, but pans that are too large are unwieldy. Number the squares in the grid and select a starting square for each sample by picking a number from a box of corresponding numbers or from a table of random numbers. Remove all arthropods from the starting square and then remove arthropods from each successively

Exhibit 12

higher numbered square. An arthropod on a line is considered to be in the square that contains its head, or in the square closest to its head. After the highest numbered square has been sampled, return to square 1. Remove and preserve at least 100 arthropods. Remove all arthropods from the last square to be picked. Do not collect Hemiptera, or Coleoptera other than Dryopoidea. Except for adult Elmidae and fifth instar Hydroptilidae larvae, which have expanded abdomens and are usually in cases, do not collect arthropods less than 3 mm long because most cannot be identified. An illuminated 5X magnifier on a long, movable arm (Luxo®) will facilitate finding and removing arthropods from the pan.

7. Preserve all arthropods in 70% ethanol for identification to genus or species in the laboratory. Isopropyl alcohol may also be used.

8. Sort and identify all arthropods to genus, except Chironomidae, which should be placed in a separate vial. When all samples have been identified to genus, species identification should be made whenever necessary and possible. This is best accomplished by working on one genus at a time and identifying species in that genus from all samples before identifying species in another genus.

9. Chironomidae are sorted to genus by placing those that look alike together. Head color, head size and shape, markings on the head, antennal length and structure, number and location of eye spots, general shape and pigmentation of the mentum, length and color of preanal papillae and setae, length of prolegs and color of their claws, and general coloration are among the characters that can be used to separate genera. Mount the two most dissimilar larvae from each group in Hoyer's medium under separate cover slips on the same slide. If both are found to be the same genus, the remainder may be assumed to be also the same and need not be mounted. If they are different, further sorting and slide mounting is needed or all must be mounted on slides. An alternative is to clear all larvae in 10% KOH and make temporary mounts in glycerine for identification.

10. Record the number of each species on a data sheet and multiply the number by the tolerance value for that species. Sum the products and divide by the total number of arthropods in the sample to obtain the biotic index for the stream. Table 1 is a general guide to the water quality of streams. Replicate samples, or both spring and fall samples, will add to the confidence of the evaluation.

Table 1. Evaluation of water quality using biotic index values of samples collected in March, April, May, September, and early October.

Biotic Index	Water Quality	Degree of Organic Pollution
0.00–3.50	Excellent	No apparent organic pollution
3.51–4.50	Very Good	Possible slight organic pollution
4.51–5.50	Good	Some organic pollution
5.51–6.50	Fair	Fairly significant organic pollution
6.51–7.50	Fairly Poor	Significant organic pollution
7.51–8.50	Poor	Very significant organic pollution
8.51–10.00	Very Poor	Severe organic pollution

[a]An asterisk denotes decreased reliability because collections were made in less than five of the 1979–80 study streams or because fewer than 10 individuals were collected.

[b]Although Schefter and Unzicker (1984) synonymized *Ceratopsyche bifida* with *C. morosa*, we found that larvae of both forms can be readily identified (Schmude and Hilsenhoff 1986). Since *C. morosa* morosa form occurs only in northern Wisconsin in clean streams while *C. morosa* bifida form occurs statewide and often in organically enriched streams, I recommend that both forms be identified.

[c]*Simulium vittatum* has a tolerance value of 7 *unless* three or more species with tolerance values of 2 or less make up at least 10% of the sample. Then the tolerance value is 4.

Exhibit 12

CHANGE IN NUTRITIONAL QUALITY OF DETACHED ASPEN AND WILLOW FOLIAGE USED AS INSECT FOOD IN THE LABORATORY

William E. Miller[1]

ABSTRACT

Leaves of *Populus tremuloides* and *Salix babylonica* held in the laboratory as for feeding insects were analyzed for total nitrogen, total phenolics, and total sugars at 0, 3, and 6 days. More often than not, the three components varied due to leaf age, time since excision, or temperature. Temporal changes altered nutritional balance and probable impact on insect performance. Results suggest that other woody plant species would not remain nutritionally stable for long in the laboratory.

Although artificial diets are available for feeding many kinds of insects in the laboratory, natural foods may be used for convenience or for more purposeful reasons. Natural foods are often used as controls in the evaluation of artificial diets (Singh 1977). For herbivores, foliage-bearing branchlets with cut ends usually in water are provided for stated periods or until consumed. While the nutritional quality of fresh foliage for insects is becoming better known, the stability of detached foliage is uncertain.

Reported here are chemical analyses of foliage from detached aspen and willow branchlets held in the laboratory as for insect feeding. The components analyzed are important indicators of nutritional quality: total nitrogen, total phenolics, and total sugars. The dietary significance of these components for insects might be succinctly characterized as positive for nitrogen (Mattson 1980) and sugars (House 1974), and negative for phenolics (Levin 1971).

MATERIALS AND METHODS

Mid-crown branch tips 20–30 cm long were cut at mid-day from 4-m-tall quaking aspen (*Populus tremuloides* Michx.) at one site. Similar sized pendant branch tips reachable from the ground were cut from a mature weeping willow (*Salix babylonica* L.). Cut ends were placed immediately in distilled water, and the branchlets promptly transferred to the laboratory for assignment to treatments. Cut ends were kept in distilled water throughout treatments.

Treatments consisted of 12-h fluorescent light photophase and four temperature regimes in controlled environment chambers: (1) constant 16°C, (2) constant 20°C, (3) day-night cycling 22-10°C, and (4) day-night cycling 28-16°C. Aspen branchlets were held at the first two temperatures, and willow branchlets at the last two. At intervals of 0, 3, and 6 days, 8–12 leaves with petioles were harvested from branchlets sampled along their length. Sampled branchlets were not returned to the experiment.

Harvested leaves of each treatment were pooled in a Petri dish, and immediately stored at -15°C. The contents of each Petri dish were later freeze-dried for 45 h and ground in

Exhibit 12

a Wiley mill to pass a 40-mesh screen. Total nitrogen was measured by a micro- Kjeldahl method, total phenolics by photocolorimetry using Folin-Denis reagent (Rosenblatt and Peluso 1941), and total sugars by high-pressure liquid chromatography.

Analyses of both species were carried out with branchlets of different ages: partly expanded leaves collected 16 May, and fully expanded leaves collected 10 June. On neither date was there noticeable natural insect or other injury to the foliage of either species. Foliage from the same sources in other years was used to feed insects in studies published (Miller 1977, Muggli and Miller 1980) and unpublished.

RESULTS

Nitrogen was the most stable component (Fig. 1). In aspen expanding (May) foliage, it ranged from 5.0 to 6.0%, apparently increasing at both temperatures at first, then leveling off. It persisted near 2.0% at both temperatures in expanded (June) foliage. In willow expanding (May) foliage, it ranged from 4.3 to 4.9%, and in expanded (June) foliage, from 3.6 to 3.8%, varying little with temperature regime.

Phenolic content was nearly stable over the treatment period (Fig. 1). In aspen expanding (May) foliage, phenolic content ranged from 6.1 to 7.2%, and in expanded (June) foliage, from 13.8 to 15.6%, where it appeared to increase at both temperatures. In willow expanding (May) foliage, it varied from 3.9 to 5.0%, and in expanded (June) foliage, from 4.7 to 7.5%. It appeared to increase in willow leaves at both temperature regimes.

Sugar content declined steadily from 15 to less than 11% in aspen expanding (May) foliage at both temperatures, and from 16 to less than 14% in expanded (June) foliage (Fig. 1). In willow foliage of both ages, sugar content increased from 16% at the lower temperature regime, then declined, and at the higher temperature regime, it changed in the opposite way.

DISCUSSION

Because this study was replicated but once, sampling variation in components is largely unknown. Results are therefore preliminary.

The large differences in total nitrogen and total phenolics between aspen expanding (May) and expanded (June) foliage (Fig. 1) conform with well known seasonal changes in these components (Mattson 1980). The lesser corresponding differences between willow expanding (May) and expanded (June) foliage are partly due to willow flushing a week or more earlier than aspen, and there being less difference in willow leaf expansion between collection dates.

No pronounced trends related to temperature emerged for nitrogen in either species. For total phenolics, there may have been more accumulation in expanding (May) leaves of both species at lower than at higher temperatures, and the opposite in expanded (June) foliage. Temperature effects for total sugars were mostly nondescript, except for the divergence-convergence sequence in willow leaves (Fig. 1).

Insects benefit in direct proportion to foliar nitrogen content (Mattson 1980). Other things being equal, an increase in total nitrogen from 5.0 to 5.5 or 6.0%, as occurred in aspen expanding (May) foliage (Fig. 1), should benefit insects measurably. However, concurrent increase in phenolics can reduce nitrogen availability to insects (Mattson 1980).

The temporal increases in phenolics (Fig. 1) are similar to those following mechanical damage to intact foliage (Rhoades 1983). Results here supplement evidence of a localized phenolic response. Few dosage-response studies of phenolics and insects are available. Those reported show that for one-compound tests, amounts from 0.2 to 0.4% in artificial diets prolonged development, reduced pupal weights, and increased mortality compared with amounts from 0.1 to 0.2% (Shaver and Lukefahr 1969). Because phenolics appear

Exhibit 12

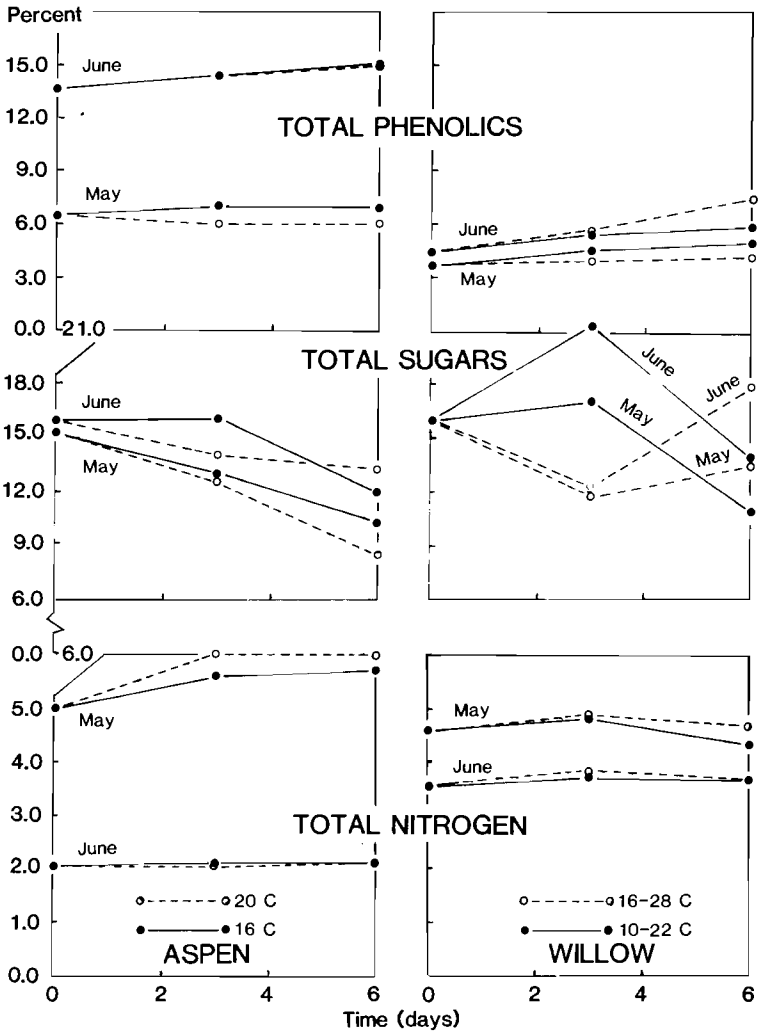

Fig. 1. Dry weight percentages of three chemical components of expanding (May) and expanded (June) aspen and willow foliage on days 0, 3, and 6 at different temperatures in the laboratory.

to act in a dosage-dependent manner, buildups as in aspen and willow expanded (June) foliage may adversely affect insect performance. However, undetermined facors like specific composition of the phenolics, and capacity of some insects to overcome their adverse effects, may be important.

Although sugars are important feeding stimulants, their temporal fluctuation in detached aspen and willow foliage (Fig. 1) lies in a nutritionally significant range.

Exhibit 12

Different insects have different qualitative and quantitative sugar requirements and tolerances (House 1974); despite such complexities, insects investigated by Beck (1957) and Matsuoka (1965) benefited in direct proportion to sugar concentrations between threshold and inhibitory levels. For another species investigated by Harvey (1974), change in sucrose concentration from 1 to 4% in artificial diets produced female pupae 65% heavier in less time. If insects of similar constitutions consumed aspen and willow foliage at some combinations of leaf age and temperature in this study, they would encounter marked temporal changes in extractable energy.

CONCLUSION

Detached aspen and willow foliage not immediately consumed does not retain its original balance of nutritionally important components, although some components may persist at original levels under some conditions. Conditions of change in investigated components include age or degree of leaf expansion, time, and temperature. The changes in detached leaves may not differ greatly from those on intact leaves of the source plants. Overall nutritional quality cannot be estimated for detached aspen and willow foliage because not enough is known about interactive or compensatory effects of changing components for specific insects. However, to avoid unknown and unwanted variation in insect performance, investigators should discard detached foliage not consumed within a few hours.

The similarity in changes observed here between aspen and willow foliage suggests that detached foliage of other woody plant species likewise does not remain nutritionally stable for long under insect rearing conditions in the laboratory.

ACKNOWLEDGMENT

Major support for this study was provided by the USDA Forest Service North Central Forest Experiment Station, St. Paul, MN. Total nitrogen was determined by Department of Soil Science Analytical Services, University of Minnesota; sugars by Ingman Laboratories, Inc., Minneapolis, MN. I thank S. R. Palmer for phenolic analyses, and L. S. Bauer for laboratory and other assistance.

Exhibit 12

A STUDY OF THE BIOLOGY OF *RHOPALOSIPHUM PADI* (HOMOPTERA: APHIDIDAE) IN WINTER WHEAT IN NORTHWESTERN INDIANA[1]

J. E. Araya[2], J, E. Foster[3], and S. E. Cambron [3]

ABSTRACT

Periodic collections of the bird cherry-oat aphid, *Rhopalosiphum padi*, during two years revealed small populations on winter wheat in Lafayette, Indiana. The greatest numbers were found on volunteer wheat plants before planting. In the autumn, aphids were detected on one-shoot plants by mid-October and also early March. The populations remained small until mid-June. We conclude that the aphid feeding did not significantly affect the plants, but helped spread barley yellow dwarf virus.

The bird cherry-oat aphid, *Rhopalosiphum padi* (L)., is an important insect pest of cereals, damaging the hosts both by feeding and by transmitting barley yellow dwarf virus (BYDV) (Stern 1967, Kolbe 1973). In the United States, severe epidemics of BYDV in small grains apparently occurred prior to 1951 (Anon. 1959, Bruehl 1961, Rochow 1961). The aphid has a wide range of hosts that include various species of cereals and grasses as summer hosts, and *Prunus* spp. as fall and spring hosts (Richards 1960, Robinson and Hsu 1963).

Several reports documented losses in small grains due to feeding damage, BYDV, and their combined action. For example, in Indiana yield losses were estimated at about 27.5% in oats due to infection by BYDV in 1959 (Caldwell et al. 1959), while in Mississippi, reported losses in oat yields were as high as 30–40% (Rothman et al. 1959). In Canada, seed weight losses of 60–86% occurred for spring wheats naturally infected with BYDV in 1978 (Gill 1980). Fall infections of BYDV on hard red winter wheat in Kansas caused yield reductions of 25–60%, while spring infection yield reductions were 5–35% (Palmer and Sill 1966). Similar results were obtained by Carrigan et al. (1981).

In Italy, spring barley, immediately after sprouting became infested by aphids that had previously developed on maize (Suss and Colombo 1982). In the autumn, aphids (especially *R. padi* and *Sitobion avenae* (Fabricius)) infested the basal leaf-sheaths of maize, from which they migrated to the tender shoots of well-fertilized wheat and barley when the maize plants dried up. A relationship was established between spring cereals and *R. padi* and *Metopolophium dirhodum* (Walker), which were able to transmit BYDV from maize (on which it produced no symptoms) or wild grasses and pass it on to wheat and barley.

The interaction of *R. padi* with cereals warrants the study of its biology and makes the study of its relationships with BYDV a necessity. The objectives of this research were to

Exhibit 12

study the life cycle of *R. padi* on winter wheat in the field, in order to evaluate the feasibility of controlling alate migrant aphids (BYDV vectors) in early fall, and late spring crops.

MATERIALS AND METHODS

The number of *R. padi* on wheat was determined from weekly samples of 50 stems. These were taken randomly from four blocks with three wheat plots each, corresponding to three different wheat rotations with corn and soybeans from the USDA-ARS Integrated Pest Management Project at the Purdue University Agronomy Farm located near Lafayette, Indiana. Samples were taken throughout the year when the crop was present for two years, starting in September 1982 with volunteer wheat plants. Winter wheat seedlings were sampled during the fall of 1982, and in the same fields during spring 1983. The second season commenced October 1983 and continued through June 1984 except in midwinter.

Since many *R. padi* develop within the seedling leaf whorls, the sample plants were cut at ground level and placed in vials in 70% alcohol. The aphids per seedling or per stem in taller plants, were counted later in the laboratory. This method has proven to be effective in determining the proportions of different morphs of *S. avenae* in field studies in England by Dewar et al. (1982).

RESULTS AND DISCUSSION

The numbers of *R. padi* collected periodically on winter wheat plots during two crop cycles (1982–83 and 1983–84) appear in Figure 1. The data are expressed as the average number of nymphs, apterae, and alatae collected on 50 stems.

The wheat plots where the aphids were collected were part of a study with three different rotations including wheat, corn, and soybeans, the most common crops in Indiana. The aphids collected are representing the average number occurring in winter wheat rotated with other crops.

Aphid numbers were low during both crop years. The highest populations occurred in 1982 on volunteer wheat plants just prior to fall planting (Fig. 1). These and other graminaceous plants were important sources of aphid infestation and BYDV inoculum for wheat seedlings in October. The small seedlings are often invaded by alate aphids that are efficient vectors of the virus (Gill 1970, 1972). Even though present in small numbers, they spread the virus in the crop when it is most susceptible (Endo and Brown 1963, Smith 1967). It has been reported that a fall infection of winter wheat by BYDV is more severe than a spring infection (Palmer and Sill 1966). During a mild winter, some aphids may survive, and although normally inactive during the cold months (Forbes 1962, Harper and Blakeley 1968), they become active and start reproducing parthenogenetically earlier in spring (Dixon 1971), causing larger infestations than average.

In 1983, the first aphid nymphs were collected on 5 March, when the plants were in the one-leaf stage (stage 1 of the Feekes scale [Large 1954]) and probably were progeny of winged immigrants that had arrived earlier. The first winged individuals were collected on 20 May. The populations were relatively small until mid-June, when aphids were easily detected by sight; however, by this time the crop had flowered (stage 10.5.4 of Feekes) and most of the aphids were below the heads. It is thought that plants can withstand such infestations without any adverse effect on the yield. As the crop matured and the temperatures of summer increased, the populations declined to nearly negligible levels. The heat and drought of the summer of 1983 are believed to have been the cause of the small population available to attack wheat the following fall. The aphids were detected on 14 October 1983, on plants at the one-leaf stage, and winged immigrants were collected on 26 October. The population remained small until 8 June and reached a peak on 15 June. This increase occurred after all the heads had formed and were out of the sheath

Exhibit 12

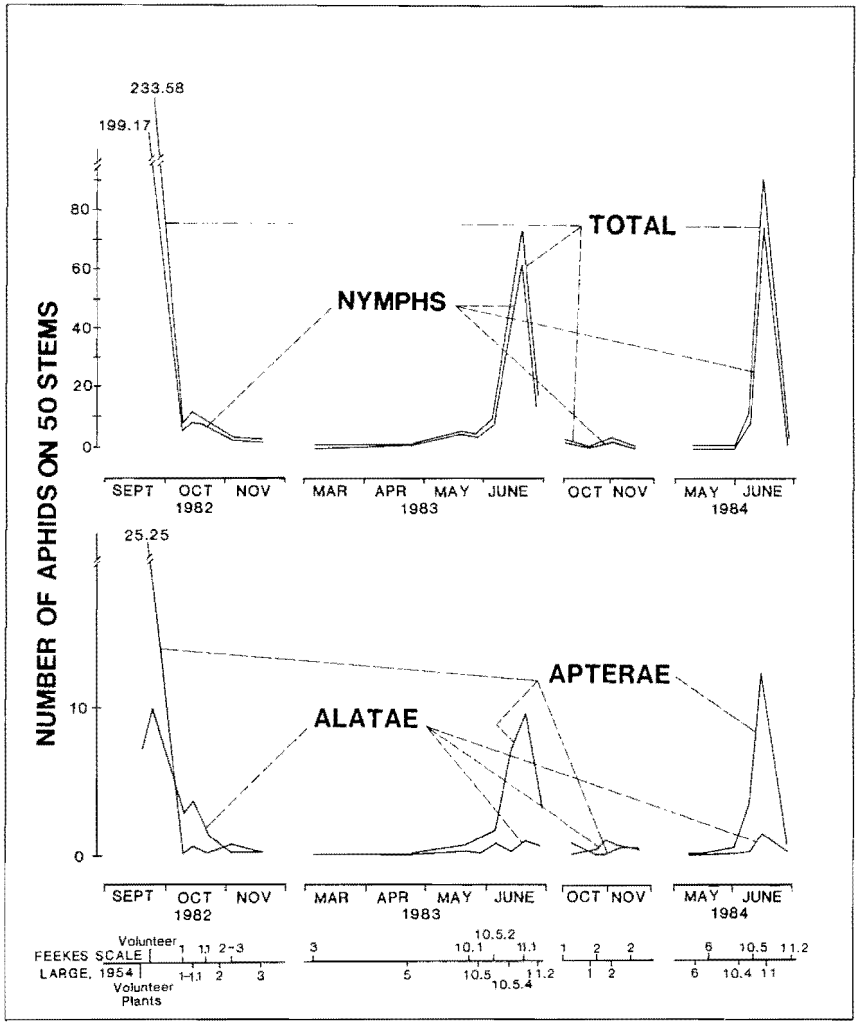

Figure 1. Numbers of ***Rhopalosiphum padi*** collected on wheat plots in the Integrated Pest management Area at the Purdue Agronomy Farm

(stage 10.5 of Feekes); the maximum number occurred during the ripening (stage 11), and was of a relatively low level. We conclude that in 1984 the crop was unaffected by direct aphid feeding.

From this study, aphids invaded winter wheat crops in the area of Lafayette, Indiana, early in the season, enabling winged immigrants to spread BYDV when the crop was most susceptible to the virus. Relatively large numbers of winged aphids such as found on volunteer wheat in September of 1982, pose a danger to wheat crops in Indiana that may

Exhibit 12

become infected very early with BYDV. This danger may increase as minimum tillage practices gain widespread acceptance, leading to more volunteer wheat.

ECONOMIC THRESHOLDS FOR CENTRAL EUROPEAN AND NORTH AMERICAN WHEAT INSECTS[1]

Stanley G. Wellso[2] and Theo Wetzel[3]

ABSTRACT

The economic thresholds for implementing control of 24 wheat insect pests from Central Europe and North America are discussed. Additional studies on wheat pests are necessary to better define the existing thresholds.

Wheat (*Triticum aestivum* L.) has played a major role in human economic and social development, and provided more nourishment than any other food crop (Inglett 1974). Much information has been published about the relationship of insects to losses in wheat and their control. A primary task of many entomologists is to evaluate insect damage to a crop relative to its yield and biomass loss; from these data economic thresholds can be established to reduce future losses. For wheat, however, the situation is more complex than just described because insects usually are not the sole or primary consideration causing yield reduction, and often it is difficult to correlate the economic losses directly to insect numbers and their damage. Many other factors influence wheat yield, e.g., the genetic potential of the cultivar, or cumulative environmental and biological effects during the growth and development of the plant including diseases, weeds, and mineral and water deficiencies or excesses.

Boyer (1982) suggested that U.S. wheat productivity falls far short of the potential of the crop and noted the following wheat data from the USDA (1965): record yield, 14,500 kg/ha; avg. yield, 1880 kg/ha (or 13.0% of the record yield); loss from diseases, 336 kg/ha (2.3%); insects, 134 kg/ha (0.9%); weeds, 256 kg/ha (1.8%); other unfavorable environmental conditions, 11,900 kg/ha (82.0%). The major losses in wheat are attributed to climate and soil conditions and include drought, excess water, hail, and wind. Pesticide usage in 1955 equalled 1% of the total crop value, and this had risen to 4.6% by 1968 (Neumeyer et al. 1969). About 3.8% of all insecticides used in the U.S. in 1985 were used on wheat pests (USDA 1985). This percentage is low relative to the value of the crop and is due, in part, to compensation of wheat to insect attack by tillering.

In this paper, we compare the recommended thresholds for control of wheat insects in the United States and Central Europe (primarily the German Democratic Republic). Since the climate and some pests from the two regions are similar, evaluating the differences in small grain insect control in the two regions should bring about a better understanding of economic thresholds.

Exhibit 12

CEREAL YIELDS AND QUALITY

The world's wheat acreage is concentrated in the Northern Hemisphere with over 90% of the acreage in Eurasia and North America (Reitz 1967). Cereal losses are typically determined by the components of yield, i.e., the density of heads per unit area, the number of seeds per head ("ear" or "spike"), and the seed weight often expressed as the weight/1000 seeds. The corresponding loss percentages relative to total yield are 48% with respect to the density of the stand, 29% with respect to the seeds per spike, and 23% with respect to the weight/1000 seeds (Damisch 1970). In addition, the straw of wheat is also an important article of commerce. Cereal feeding insects may affect the quality as well as quantity of the grain. Wratten (1975, 1978) and Freier and Wetzel (1976) found a reduction of grain protein of wheat and assumed that it was probably due to nitrogen depletion by aphids feeding on the heads.

INSECT PESTS OF WHEAT

Many factors must be considered before reaching the decision that insecticides should be used to control an insect pest. The following are perhaps the most important criteria that should be considered when evaluating pest damage of a crop: (1) the stage of growth at the time of the infestation (spring or fall plants, tillering or heading); (2) the size and expected duration of the infestation; (3) the transmission of diseases or the injection of toxins that injure the crop more than nutrient removal; (4) other pests attacking the crop; (5) the vigor of the plants and their ability to tolerate or withstand attack; (6) the nature of any host plant resistance; (7) the presence of predators and parasitoids to suppress the pest; (8) the yield potential or value of the crop under present light, soil, and moisture conditions; and (9) the cost of control (the insecticide and application) relative to other expenditures already incurred during the development of the crop and relative to the future anticipated monetary return.

Many insect pests of North America were introduced unknowingly by immigrants. Since most immigrants came from Europe, it is appropriate to compare and contrast the thresholds for insect control of wheat insects of North America with European thresholds. We selected only those insects that are more important pests, although other insects are occasionally classified as pests. In addition, both areas are quite large; thus we used the most typical thresholds for both continents.

Table 1 provides information on the number of insects per unit area or plant that serve as thresholds before initiating chemical control. No specific insecticides are recommended because these vary from region to region and tend to change as new products become available. Of the 24 pest groups or species listed in Table 1, eight are from both continents, and eight are each from Europe or North America. The recommended thresholds are quite similar for the species that occur on both continents.

CEREAL LEAF BEETLES

Control measures for *Oulema* spp. are recommended when three or more eggs or larvae, or both, are present per plant, or one larva or more per flag leaf. These leaf-feeding insects often prefer to attack wheat in one or two fields in an area, and their populations then may warrant insecticidal control. In the 1960's and early 1970's, the cereal leaf beetle, *Oulema melanopus* (L.), was frequently controlled in North America with insecticides. In the 1970's, four species of Europen parasitoids were established in North America, and the need for insecticidal control was greatly reduced from 1975 to 1985. These leaf feeding insects, *Oulema* spp., are considered sporadic pests in Europe.

Exhibit 12

Table 1. Current thresholds for control of common wheat pests in Central Europe and North America

Insect Pest	Central Europe (CE)	North America (NA)
	ROOTS	
COLEOPTERA		
Phyllophaga spp.	N/A[a]	32–43 larvae/M^2[b,c]
Agriotes spp.	2–3 larvae/0.05 × 0.15 M core causes 10% loss[d]	N/A
Melanotus spp.	N/A	Occasional pests
Eleodes spp.	N/A	do.
HOMOPTERA		
Rhopalosiphum insertum (Walker)	Occasional pests	N/A
	STEMS AND BLADES	
ORTHOPTERA		
Grasshoppers	N/A	8/M^2 on small plants[e]
LEPIDOPTERA		
Pseudaletia unipunctata (Haworth)	N/A	4/0.3M of row[e]
COLEOPTERA		
Zabrus tenebroides Goeze	1–2 larvae/M^2 in autumn[f]	N/A
Oulema melanopus (L.)	1 or more eggs or larvae/flag leaf[f]	3 eggs or larvae/plant or 1 or more larvae/flag leaf[e]
Oulema lichinis (Voet)	1 or more eggs or larvae/flag leaf[f]	N/A
HEMIPTERA		
Blissus leucopterus Say	N/A	Occasional pest
HOMOPTERA		
Schizaphis graminum Rondani	15–25 aphids/plant between flowering and milk stage[g]	10–15 cm, 50 aphids/plant[h] 15–25 cm, 200 do. 46–51 cm, 300 do. > 76 cm, 800 do.
Sitobion avenae (Fabricius)	do.	Occasional Pest
Rhopalosiphum maidis Fitch	do.	do.
Rhopalosiphum padi (L.)	do.	do.
Sitobion fragariae (Walker)	do.	do.
Metropolophium dirhodum (Walker)	do.	N/A
DIPTERA		
Delia coarctata (Fallen)	125 larvae/M^2 in soil Jan.–Mar.[i] 60–90 eggs/M^2 in soil Sept.[f]	N/A
Mayetiola destructor (Say)	1–6 larvae/plant[f]	20% stems infested[j]
HYMENOPTERA		
Cephus pygamaeus (L.)	30 larvae/M^2 in stubble (indicator for popln. next year)[f]	Occasional pest
Cephus cinctus Norton	N/A	70% tunneling – 10% loss in grain[g]
	HEADS	
HOMOPTERA		
Sitobion avenae (Fabricus)	3–5 larvae/head at flowering and 60–80% infestation[f]	Occasional pest
DIPTERA		
Sitodiplosis mosellana (Gehin)	1 ♀/3 heads just before flowering (ca. 13 larvae/head)[k]	1 ♀/head at flowering[k]
Contarina tritici (Kirby)	1 ♀/head at start of flowering[f]	N/A
Haplodiplosis equestris (Wagner)	5 larvae on culm on internode below the head (13% loss)	N/A
Meromyza americana Fitch	N/A	Control when infestation > 15%[m]

Exhibit 12

CEREAL APHIDS

Rabbinge and Coster (1984) noted that cereal aphids cause direct yield loss through assimilate consumption and changes in the nitrogen balance, and indirect yield loss through honeydew excretion affecting photosynthesis, senescence, and pythotropic fungi. In addition, their ability to transmit various cereal diseases must always be considered when evaluating the need for control.

Aphid control recommendations are more variable, with insecticidal control being implemented when aphid numbers per plant in Europe are 15–25 near flowering or in the milk stage. The guidelines for aphid control in North America typically use crop height while Europeans use host maturity, and both use number of aphids per plant or linear foot of row. Although the current recommendations are not species specific, greenbugs, *Schizaphis graminum* (Rondani), whose saliva is much more phytotoxic than the saliva of the other aphids listed in Table 1, usually cause more cereal damage (Wadley 1929). Cramer (1967), summarizing statistics for 1965 from the USDA (1965), listed the greenbug as causing more wheat yield loss (23.3%) than any other insect. Coppock et al. (1984) noted that parasitoids occasionally attack enough greenbugs in the field to reduce infestations below economic levels, and that mummified greenbugs can be used to evaluate the presence of the parasitoid. In Europe the English grain aphid, *Sitobion avenae* (Fabricius), requires control on wheat heads; in North America other aphids attack small grains, but generally only greenbugs require control. In general, economic thresholds are less precise for aphids than many other insects because of the low correlation between aphid numbers and yield loss (Rabbinge and Mantel 1981). Although the transmission of diseases by insect vectors has not been mentioned specifically, some aphids may become more mobile after receiving sublethal or slow killing insecticides (Broadbent 1969). The aphids may move more frequently from plant to plant feeding on many more plants, thus innoculating them with viruses that are transmitted mechanically on their stylets in less than 1 min. of feeding time, in contrast to the less mobile untreated insects. Fortunately, the most important insect-transmitted disease of wheat, barley yellow dwarf, is not transmitted as rapidly, and insecticidal control may be helpful, but a definitive study on barley yellow dwarf transmission is still pending. The situation becomes more complex when one notes that the barley yellow dwarf viruses (or strains) exhibit varying degrees of specificity among grass feeding aphids (Sylvester 1980).

HESSIAN FLY

The Hessian fly, *Mayetiola destructor* (Say), of European origin, is not a major pest there, but is a very serious wheat pest in North America. Insecticidal control is typically not used, but control is warranted where the percentage of stems infested is about 20% (Hill et al, 1943). The use of resistant varieties in combination with the fly-free date are the principal control methods. The causative biotype is identified based on its survival on wheats having different genes for resistance, and the proper resistance is incorporated into commercial varieties by plant breeders to suppress the infesting biotype(s). In 1974, 16 million acres in North America were planted with Hessian fly resistant varieties (Gallun 1977).

WHEAT BLOSSOM MIDGES

The orange wheat blossom midge, *Sitodiplosis mosellana* (Gehin), was not considered a major pest on either continent until 1983, when a $30 million loss to spring wheat occurred in northeast Saskatchewan, Canada (Olfert et al. 1985). They found that one, two, three, or four larvae per kernel resulted in an infestation level of 38, 58, 78, and 96%, respectively. In addition, infestations of 30, 60, and 90% reduced spring wheat yields by 40, 65, and 79%, respectively. Usually fewer than 10 larvae are present per

Exhibit 12

wheat head (ear), and seed weight may be significantly different between infested and noninfested heads. Although the midge is not dependent upon the presence of glume blotch, *Septoria nodorum* (Berk.) Berk., to attack, Wellso and Freed (1982) found that a positive association exists between the insect and glume blotch with more larvae present in those heads infected with glume blotch. In Europe, the lemon wheat blossom midge, *Contarinia tritici* (Kirby), appears to be more abundant than the orange wheat blossom midge, and its larvae feed on the wheat flower, killing the stigma and preventing pollination and grain development. Control in Europe is recommended when one or more adults are present per ear (head) when sampled throughout the field.

WHEAT STEM SAWFLIES

The European wheat stem sawfly, *Cephus pygmaeus* (L.), attacks spring wheats more than winter wheats and is a more important pest in Europe than North America. In North America, it is found only in northeastern United States and adjacent Canada, while its European distribution is greater. Another species, the wheat stem sawfly, *Cephus cinctus* Norton, is economically more important in North America as it attacks wheat west of the Mississippi River, primarily in North Dakota, Montana, and western Canada. Solid stemmed cereals are resistant to *C. cinctus* and deter oviposition and larval development. Insectidical control has not been very successful, and burning the straw and deep plowing have helped reduce sawfly populations (Bonnemaison 1980).

OTHER WHEAT PESTS

The other pests listed are from either Europe or North America, and, even within these areas, may be economically detrimental in only part of the wheat growing area. In some years, grasshoppers in North America may be very important pests, especially west of the Mississippi River. They are more important in years that are drier than average, as egg hatch is often reduced in moist years by soil-inhabiting fungi. Grasshoppers require control when 6–12 nymphs/m^2 are present. Various cutworm species and the armyworm, *Pseudoaletia unipuncta* (Haworth), may be important pests occasionally. The cyclic nature of these pests in the past seems to be related to favorable environmental conditions. With greater emphasis on minimum tillage practice, these insects may become more important economic pests. Chinch bugs, *Blissus leucopterus* Say, are only an occasional pest on small grains in Kansas and adjacent states. This insect may develop in wheat or grasses, stunting some plants or causing them them to die in small areas. This insect may become a serious pest to corn and sorghum after the wheat is harvested. The wheat stem maggot, *Meromyza americana* Fitch, damages spring wheat more than other cereals with losses ranging from a maximum of 9% with averages of 1–3% in South Dakota (Kieckhefer and Morrill 1970). The larvae feed within the culm and may cause the heads to die. Wireworms, including *Melanotus* sp., *Eleodes* sp., and *Agriotes* sp. may live in the soil from 2 to 6 years with the remaining larvae moving very far from the oviposition site. They feed on the wheat roots and may cause spotty damage in the field. Like armyworms and cutworms, these insects may become more abundant under minimum tillage practices. June beetles, *Phyllophaga* spp., like wireworms, may occasionally damage the roots of cereals.

Wheat bulb fly, *Delia coarctata* (Fallen), larvae move through the soil in Eurasian cereal fields and penetrate the underground stem (crown). The larvae move upward through the culms and feed upon the terminal buds, and may cause as much as 10% crop loss (ABMAC 1965).

We have described and compared the major damage to wheat by Central European and North American insect pests. Most entomologists agree that the current recommended thresholds need to be improved and that this will occur only after we better understand the insect-plant interactions. Since environmental stresses cause the major losses, the

Exhibit 12

relationship of insects, weeds, and diseases to each other and during these various stresses must be more clearly defined relative to crop loss. We are improving our biological and environmental monitoring and sampling, and this, together with a better understanding of the tolerance of plants to withstand insect attack, will bring about a better understanding of yield losses.

INFORMATION FOR AUTHORS

Papers dealing with any aspect of entomology will be considered for publication in *The Great Lakes Entomologist*. Appropriate subjects are those of interest to amateur and professional entomologists in North Central States and Canada, as well as general papers and revisions directed to a larger audience while retaining an interest to readers in our geographical area.

Manuscripts must be typed, double-spaced, with wide margins on white 8-1/2 × 11″ or equivalent size paper, and submitted in *duplicate*. Footnotes, legends, and captions of illustrations should be typed on separate sheets of paper. Titles should be concise, identifying the order and family discussed. The author of each species mentioned must be given fully at least once in the text. A common name for each species or group should be given at least once when such a name exists. The format of references should follow that used in recent issues. Photographs should be glossy. Drawings, charts, graphs, and maps must be scaled to permit proper reduction without loss of detail. Contributors should follow recommendations of the *Council of Biology Editors Style Manual*, 5th ed.

Papers published in *The Great Lakes Entomologist* are subject to a page charge of $30.00 per published page. Members of the Society, who are authors without funds from grants, institutions, or industry and who are unable to pay costs from personal funds, may apply to the Society for financial assistance.

Authors will receive page proofs, together with an order blank for separates.

All manuscripts for *The Great Lakes Entomologist* should be sent to the Editor, Dr. D. C. L. Gosling, 69063 Wallowa Road, White Pigeon, Michigan 49099, USA. Other correspondence should be directed to the Executive Secretary (see inside front cover).

Aquatic Survey Assessment

---

1. INTRODUCTION

The following letter report describes the results of the aquatic habitat assessment and benthic community survey work performed by ARCADIS on October 9, 2014 within the East Fork Armells Creek (EFAC).

2. SAMPLE LOCATIONS

Aquatic surveys within EFAC were conducted to support existing permitting efforts for surface water discharges, per recent comments received by Montana Department of Environmental Quality (MDEQ). These recent comments included a June 3rd, 2014 MDEQ letter to Western Energy Company (WEC) stating that their application for Permit ID C1984003B Amendment AM4 was deficient and that WEC needed to "confirm, based on current and future anticipated concentrations in the stream, that uses have not or will not be impaired (MDEQ 2014)." In addition, MDEQ requested that WEC "conduct a current aquatic survey along stretches of East Fork Armells Creek (EFAC) adjacent to the Rosebud Mine permit areas (Areas A, B, and C) to identify assemblages of aquatic life using the stream habitat." MDEQ states the data collected from the aquatic survey will be used for future permit revisions in Area A and Area C.

Prior to conducting the aquatic survey, two ARCADIS scientists performed a reconnaissance along the stretch of EFAC adjacent to the Rosebud Mine permit areas (Areas A, B, and C) on October 9, 2014. The reconnaissance was performed to confirm existing drainage conditions (i.e., wetted extents and potential

Exhibit 11

habitat types) that would be representative of the current EFAC aquatic community. Based on the largely homogeneous aquatic habitat observed, consisting of primarily low-gradient drainage with minimal flow, heavy siltation, and riparian and emergent wetlands, two representative locations were selected to survey the current benthic community. The attached Figure 1 indicates the locations of EFAC1 and EFAC2. Location EFAC1 is positioned lower in the EFAC drainage. Compared to more upstream stretches, EFAC1was less impounded, had more visible flow sections and a higher degree of meander and sinuosity patterns in the drainage. This location had an established riparian zone with herbaceous, shrub, and tree vegetation layers, and some in-channel woody debris. Location EFAC2 is found in the middle portion of the EFAC drainage and near the upper extent of the wetted conditions observed during the reconnaissance. EFAC2 represents a low-gradient drainage. Compared to EFAC1, this location had a minimally developed flowing channel, relatively wider and more impounded wetted channel, and less meander and sinuosity. The riparian zone contained emergent vegetation.

3. SURVEY METHODS

Benthic macroinvertebrates were surveyed on October 9, 2014. Survey protocols and taxonomic identification of the benthic community organisms followed both MDEQ's sampling and analysis protocols *Sample Collection, Sorting, Taxonomic Identification, and Analysis of Benthic Macroinvertebrate Communities Standard Operating Procedure* (MDEQ SOP) (MDEQ 2012) and USEPA's *Rapid Bioassessment Protocols for Use in Streams and Wadeable Rivers* (RBP) (Barbour et al. 1999). The MDEQ SOP details a semi-quantitative reach wide sampling technique to collect samples from a known area, which allows the estimation of population density, in addition to diversity and abundance. This sampling technique includes the use of a d-frame net at a total of 11 transects within a sampling reach to be collected as kick samples working downstream to upstream. Barbour et al. (1999) recommends either 40 times the wetted stream width or a representative 100 meter reach (as a minimum for smaller-sized streams) for sampling. Based on drainage conditions, an approximate 100 meter reach was established at each benthic community survey location. Following RBP methodologies, general aquatic habitat conditions were detailed to include measurements of water quality parameters and physical characterization of riparian vegetation, instream features, presence of aquatic vegetation and large woody debris, and sediment and substrate components.

Based on existing habitat observed, the number of transects to provide a representative benthic community sample was reduced down from 11 to 8. Based on professional judgment, the MDEQ SOP methodology and its applicability to these low gradient survey reaches was compromised by the lack of riffles, exposed inorganic substrate, and the largely homogeneous habitat observed within each of the survey reaches. The individual area (1 ft^2 – 0.093 m^2) sampled within each survey reach was increased slightly (1.3 ft^2 – 0.12 m^2) to account for the difference and to obtain a representative 1 m^2 area sampled for the reach. Benthic organism abundance was noted throughout the collection process and available habitats were sampled to provide the representation of the existing community. For EFAC1, this included kick net samples, sweeps of emergent vegetation, and hand-picking and rinsing of functional large woody

debris. For EFAC2, the primary habitat was emergent vegetation and exposed root mats of emergent vegetation within a limited free-flowing narrow channel, which was sampled primarily by sweeping emergent vegetation and kicking substrate and root mat and detritus into kick net.

A representative area (approximately a 1.3 ft^2 quadrat) was selected along each transect to collect each of the kick samples. In an area of flow, the kick sample was collected within the representative area, by using hands with a hand trowel or by feet to disturb the area and wash and large rocks, sticks, or debris into the net for a period of 30 seconds. For slackwater habitats with emergent vegetation, the kick net was swept through the vegetation for 30 seconds within the representative area. All individual kick net samples were composited into a 5 gallon bucket and then elutriated to remove large debris. Contents were sieved using a standard #35 (500 micron) mesh size and then transferred to a wide-mouthed plastic sample jar. Samples were preserved with 90% isopropyl alcohol, and sent to Normandeau Environmental Consultants (Normandeau) in Stowe, Pennsylvania, for taxonomic identification. Normandeau taxonomic identification and community sample processing followed by MDEQ protocols to subsample an approximate 500 ± 10% organisms.

Water quality parameters were collected using a YSI 556 multimeter and a Hach 2100P turbidity meter at representative locations within EFAC1 and EFAC2.

4. RESULTS

The aquatic conditions of EFAC are indicative of low-gradient streams, with influences from a mixture of water origins (seasonal runoff, groundwater), and supportive of a tolerant benthic community. Existing habitat is characterized by heavy siltation, low flow, and high amount of organic substrates, with prevalent emergent vegetation along riparian zones.

Table 1 provides a summary of the temperature, specific conductance, dissolved oxygen, pH and turbidity measured at each location. Table 2 summarizes the main physical characteristics and substrate observations for both EFAC1 and EFAC2. Attachment 1 includes observations included during the RBP assessment of aquatic habitat and a set of photographs detailing the habitats surveyed at EFAC1 and EFAC2.

Table 3 provides the results of the taxonomic identification for the EFAC1 and EFAC2 benthic community samples. Community diversity and abundance was similar between the two locations, with a total of 25 and 26 taxa identified at EFAC1 and EFAC2, respectively. Communities were represented by eight orders of aquatic organisms, including aquatic worms, snails, amphipods, mayflies, damselflies, caddisflies, beetles, midges, and fly larvae. Within EFAC1, the side swimmer amphipod within the genus of *Hyalella* was the most dominant benthic organism observed. Within EFAC2, the non-biting midge within the genus of *Paramerina* was the most dominant benthic organism observed. For both locations, mainly tolerant Dipteran taxa comprised over 50% of the community, with *Hyalella* following closely at nearly 25% and

above within the community. Based on the MDEQ protocols, a community indicator metric (Hilsenhoff Biotic Index [HBI]) was calculated using Montana-specific tolerance values for identified taxa. The HBI metric represents the relative sensitivity of the sample to nutrient perturbation. The HBI, based on 2005 operable Taxonomic Units (taxonomic endpoints) found in Appendix A of the MDEQ SOP, was calculated for both locations (6.98, 7.90), and indicates “fairly poor” to “poor” conditions (Hilsenhoff 1987).

In summary, the aquatic habitat assessment and benthic community survey was conducted in general accordance with RBPs and MDEQ SOP protocols to satisfy the current deficiency letter and to support the potential for future permitting within existing areas A, B, C within the EFAC.

WCCPROD00000939

EFAC Conditions Summary

- EFAC consists of low-gradient streams with several water sources: groundwater, seasonal runoff, precipitation, NPDES permitted outfalls.
- Low flow, high organic matter content and ephemeral flows are conditions conducive of a tolerant benthic community.
- The surveys date show expected community composition:
  - Diptera dominate the community (flies) - Chironomid, Amphipod
  - Low number of taxa and total abundance
  - HBI indicates “fairly poor” to “poor” conditions (2014)

The world’s leading sustainability consultancy

ERM

A Temporal Trends Analysis: 1977 - 1978

- Organisms were sampled quantitatively in 1978 to determine the relative abundance of various species.
- Multiple sites abandoned due to insufficient flow
- Some sites sampled once due to insufficient flow

Shannon's d	2.67				2.49				1.78			

-- Reproduced from Schwer 1981

A Temporal Trends Analysis: 1977 - 1978

- Schwer (1981) found no consistency or trends noted in diversity on a sample by sample basis, due to:
  - occurrence of a patchy distribution,
  - seasonal optimums,
  - inadequate sample size and/or
  - the inability to sample all microhabitats equally." (p. 25).
- *"Unfortunately, the lack of an equal number of samples from each site prevented a meaningful description of population changes along the creek."*

Exhibit 10

WCCPROD00000945

Water Quality and Aquatic Life Criteria

- Water quality in EFAC is very variable and often exceeds EPA aquatic life criteria – as seen in 1975, 1977, 1978
- In ephemeral systems, water flow and water quality conditions may change weekly or even daily (EPA 2006).
- Criteria are available for metals – this is based on effects to sensitive invertebrates and fish
- TDS – consists of major ions (Ca, Mg, K, Na, Cl, SO_4); Precise thresholds of effect are dependent on the combination of ions in solution and the benthic organism

Exhibit 10
WCCPROD00000946

Conclusions and Recommendations

- The large amount of variability inherent within ephemeral systems, and the low quality of habitat and benthic communities, would not provide a strong indicator of water quality impacts due to mining activity.
  - Flow and natural levels of organic matter are more likely to drive aquatic community dynamic than other factors

- Although EFAC supports aquatic life, aquatic life criteria are not met.
  - Baseline conditions are a better indicator of existing use
  - Criteria are based on different organisms not present in EFAC
- Aquatic life monitoring will likely demonstrate natural variability; unlikely to demonstrate impacts from mining

Thank You – Additional Questions?

Date: June 13, 2014

Re: Application 00184 (AM 4) – 7th Round deficiency

Discussion on which direction WECo should response to the 7th round of deficiencies, received on June 3, 2014, pertaining to the Area B-East Amendment. Chris Yde with MDEQ has requested a face to face meeting to discuss the deficiencies one on one. (planned for July 7, 2014)

Aquatic Studies –

The big question "is there aquatic life in Armell's Creek?"

Items were discussed which are written into the "IMPACT ON THE PHYSICAL ENVIRONMENT" and the "FACT SHEET FOR MAJOR MODIFICATION" sections, of the Environmental Assessment of the Rosebud Mine's Draft MPDES Permit MT0023965. These items may have basis in which WECo has grounds not to conduct aquatic studies.

"IMPACT ON THE PHYSICAL ENVIRONMENT" section

Resource	[Y/N] Potential Impacts and Mitigation Measures
2. WATER QUALITY, QUANTITY AND DISTRIBUTION: Are important surface or groundwater resources present? Is there potential for violation of ambient water quality standards, drinking water maximum contaminant levels, or degradation of water quality?	[N] All direct receiving waters are ephemeral streams that flow as a result of precipitation. Discharges to receiving waters are infrequent, short in duration, and typically occur as a result of runoff that exceeds the 10-yr, 24-hr precipitation event. All effluent imitations and monitoring requirements in the modified 2012 permit are either equal to or more stringent than those in the previous (I999) permit. Self-monitoring requirements of discharges have been increased substantially to assure compliance with permit conditions and to track levels of pollutants of concern.
5. TERRESTRIAL, AVIAN AND AQUATIC LIFE AND HABITATS: Is there substantial use of the area by imp0l1ant wildlife, birds or fish?	[N] No impacts anticipated from modification of MPDES permit.

"FACT SHEET FOR MAJOR MODIFICATION" section

C. Water Quality-based Effluent Limitations

Determining the Need for WQBELs

EPA regulations at 40 CFR I 22.44(d), which are incorporated into ARM 17.30.1344 by reference, require that all discharges be assessed by DEQ to determine the need for water quality-based effluent limits (WQBELs) in the permit. Specifically, 40 CFR 122.44(d)(l)(i) states, "Limitations must be established in permits to control all pollutants or pollutant parameters that are or may be discharged at a level that will cause, have the reasonable potential to cause, or contribute to an excursion above any state water quality standard (emphasis added by DEQ)." Often, this regulation is referred to as the "reasonable potential" regulation and the process that DEQ uses to determine whether a WQBEL is required is called a "reasonable potential analysis." Thus, a reasonable potential analysis may be used to determine whether a discharge, alone or in combination with other sources of pollutants to a water body and under some set of conditions arrived at by making a series of reasonable assumptions, could lead to an excursion above an applicable water quality standard or applicable level of nondegradation policy protection.

Nondegradation

The Montana Water Quality Act includes a nondegradation policy in 75-5-303 MCA. This policy is applied during the permit application process through a nondegradation review of any new or increased source. As described in Section 1. A. above, Outfalls 030, 127, 128, 128D, 129, 136, 137, and 139 were found to be previously permitted under different names. Therefore, these outfalls are no longer defined as new or increased sources per ARM 17.30.702(18) and are not subject to nondegradation review in the modified permit. However, Outfalls 10C, 128A, 128B, and 128C are new sources; discharge at these four outfalls is considered in DEQ's nondegradation review.

The three aspects of the State nondegradation policy parallel the three "tiers" of a federal antidegradation policy as required by USEP A in 40 CFR 131.12. These three tiers are as follows:

1. Tier 1: Existing uses of State waters and the level of water quality necessary to protect those uses must be maintained and protected (75-5-303(1));
2. Tier 2: Unless authorized by DEQ through a nondegradation analysis or exempted from review under 75-5-317 MCA, the quality of high-quality waters must be maintained (75- 5-303(2)-(7)); and
3. Tier 3: The Board may not authorize degradation of State waters classified as "outstanding resource waters" (75-5-303(8)).

Regulations at ARM 17.30.701-718 address implementation of this policy. These regulations apply when someone proposes an activity of man resulting in a new or increased Source that may cause degradation.

Tier 1: Protection of Existing Uses ARM 17.30.705(2)(a) requires that, for all State waters, existing and anticipated uses and the water quality necessary to protect those uses must be maintained. As such, when tier 1 protection is applicable, effluent limitations must be developed and numeric and narrative standards apply to protect the existing and designated beneficial uses of the receiving water.

Outfalls 10C, 128A, 128B, and 128C were not previously permitted, and are considered new or increased source outfalls for the purpose of nondegradation review. Therefore, effluent limitations in this permit are derived from and comply with applicable WQS, thus ensuring the level of water quality necessary to attain and maintain existing and anticipated uses.

Tier 2: Protection of High Quality Waters The receiving water for discharges from Outfalls 10C, 128A, 128B, and 128C is an ephemeral drainage, which is not high quality water as defined at MCA 75-5-103. Therefore, the nonsignificance determination criteria of ARM 17.30.715 do not apply.

Tier 3: Protection of Outstanding Resource Waters ARM 17.30.705(2)(c) requires that, for outstanding resource waters, no degradation and no permanent change in the quality of outstanding resources

waters resulting from a new or increased point source discharge are allowed. Receiving waters for the discharges from the facility have not been designated as outstanding resources waters. Therefore this regulation is not applicable.

Proposed Water Quality-based Effluent Limits
The receiving waters are within the Yellowstone River drainage between the Billings water supply intake and the North Dakota state line, and are classified as C-3. ARM 17.30.629 establishes the designated beneficial uses for C-3 waters and prescribes the standards to protect those designated uses. However, all permitted outfalls discharge to receiving waters that hydrologically meet the definition of ephemeral [ARM 17.30.602(12)]. ARM 17 .30.637(4) is specific to ephemeral streams of all classes and prescribes the standards applicable to protect the uses of hydrologically ephemeral streams. Pursuant to ARM 17.30.637(4), the applicable water quality standards for hydrologically ephemeral streams include the prohibitions and treatment requirements in ARM 17.30.637. Therefore, the prohibitions and treatment requirements applicable to ephemeral streams in ARM 17.30.637 will apply to the permitted discharges in addition to the applicable technology based effluent limits.

The specific water quality standards for C-3 waters found in ARM 17.30.629 do not apply to ephemeral streams pursuant to ARM 17.30.637(4). Therefore, evaluation of reasonable potential to exceed the numeric standards in DEQ-7, as adopted by ARM 17.30.629, is unnecessary.

The resulting effluent limitations are summarized in Tables 3 through 9.

Also discussed: Aquatic life studies compare themselves to themselves
Aquatic life studies should be on a regular basis
Aquatic life studies are climatic in nature

John Martin summarized his meeting with John North (MDEQ) and Dana David (MDEQ) in May 2014.

- He feels that MDEQ are trying to do the right thing
- Accessing the cumulative impacts – concerned there is material damage off the mine site and what mitigation would be used if necessary.
- Chlorine issue

Other Discussions -

- Chlorine issue - secondary standard which is aquatic life standards basis. No other livestock or wildlife basis.
- SW-75 and SW-55 are in-conclusive in nature – water quality is subjective at best
- Comparison of well vs SW site?
- Possibly drill another well?
- Water Budget – Michael Nicklin stated the preliminary work for the water budget shouldn't be adverse to the mine and the "Van Voast" evaluation was reasonable.
- Lignin Sulfate – not much information out there on how the substance breaks down – organic – tree sap – MSDS....
- TDS – specifically addressed in detail in the PHC.

Conclusions –

Draft responses should have technical and scientific data clearly demonstrating our view points

- Penny Hunter will write something up for the aquatic study response. Dicki will forward the aquatic studies to Penny.
- Wade will follow up with Michael Nicklin on the water budget.
- Dicki will follow up and find information on the lignin sulfonate.

- Dicki will write the response to the TDS section. (With help from Wade if necessary)
- Short summary of todays call and what possible issues to Mike Kegley

Comprehensive Evaluation of
Probable Hydrologic Consequences
Areas A, B and C
Western Energy Rosebud Mine

1.0 INTRODUCTION

Western Energy is proposing to expand mining in Area B of the Rosebud Mine as described in AM4 (Amendment 00184). Western Energy has operated the Rosebud Mine located near Colstrip Montana in Rosebud County since 1975 (See Figure 1). The mine is operating under five separate surface mine permits (SMP) approved and regulated by Montana Department of Environmental (DEQ); C1986003A (Area A), C1984003B (Area B), C1985003C (Area C), C1986003D (Area D), and C1981003E (Area E). Figure 2 shows a site map of the Rosebud Mine.

This PHC provides the comprehensive evaluation of probable hydrologic consequences to support the Area B AM4 (Amendment 00184) application in accordance with ARM 17.24.314(3). The mining progression for this Area B-East Revision is shown on Figure 3A.

This PHC utilizes hydrologic monitoring data from Areas A, B and C in the development and evaluation of hydrologic consequences. Data from other mine areas were not included except where deemed relevant. There is no indication that Area E is hydrogeologically separated from Area B East. However, the groundwater quality and quantity in Area E may be affected by several factors not within the scope of this PHC, such as: location adjacent to the town of Colstrip and several large impoundments and the occurrence of pre-1976 historical mining (Van Voast et al., 1977).

1.1 Background

There have been many previous investigations and evaluations conducted in the vicinity of and at the Rosebud Mine. Background reports considered in this PHC include:

- *Hydrology of Area 49, Northern Great Plains and Rocky Mountain Coal*

Provinces, Montana and Wyoming, Slagle et al, United States Geological Survey, January 1983.

- *Hydrogeologic Conditions and Projections Related to Mining Near Colstrip, Southeastern Montana*, Van Voast, Hedges, and McDermot, Montana Bureau of Mines and Geology, 1977.
- *Hydrogeologic Responses: Twenty Years of Surface Coal Mining in Southeastern Montana*, Van Voast and Reiten, Montana Bureau of Mines and Geology, 1988.
- *Final Environmental Impact Statement, Western Energy Company's Rosebud Mine, Area C, Block 1*, Montana Department of State Lands, US Office of Surface Mining, 1982.

Relevant Rosebud Mine reports include baseline monitoring and investigation reports, mining permit applications, and annual monitoring reports.

1.2 Report Objectives

The objectives of this report are to:

- Present a historical summary of analyses conducted for the Rosebud Mine.
- Provide updated information using data collected through mining operations to current.
- Present an interpretative summary of the analyses of mining impacts to date associated with the Rosebud Mine.
- Present conclusions of a Probable Hydrologic Consequence analysis addressing relevant portions of Administrative Rules of Montana (ARM 17.24.304) and Surface Mine and Reclamation Act (SMCRA - 30 CFR 780.21).
- Provide baseline information per Environmental Resources and ARM 17.24.314 Plan for Protection of the Hydrologic Balance necessary to evaluate probable hydrologic consequences in association with the proposed expansion.

Data used for this analysis are from a period extending from the early 1970s to present. Data collection activities in conjunction with the existing permit are also relevant to the proposed expansion.

1.3 Approach

Numerous previous investigations and hydrologic monitoring activities have been performed at the Rosebud Mine resulting in a very large amount of hydrologic data. Compilation, presentation, and evaluation of the available data allow for the identification and evaluation of probable hydrologic consequences beyond those developed based on baseline data.

Hydrologic consequences have been identified in previous permit applications. These are evaluated in comparison with the available hydrologic data.

The hydrologic data are condensed to statistical tables to allow identification of hydrologic impacts, including water quantities and quality as well as comparison to water quality standards. This PHC includes hydrologic data collected up to water year (WY) 2011. Data collected during WY 2012 (October 1st 2011 to September 31st, 2012) are presented in the 2012 Annual Hydrologic Report. The focus of this PHC is on hydrologic data collected within and near mine Area A, B and C permit boundaries. In addition, hydrologic data from Areas D and E were used to evaluate spoils water quality and groundwater level recovery rates.

The key hydrologic components that make up the hydrologic balance include:

- Climate
- Topography and Geology
- Erosion and Sediment Yield
- Surface Water (Stream Water)
- Springs
- Ponds
- Wetlands
- Groundwater

The key time-frames of interest include:

- Baseline (pre-mining)
- Short-term (during mining and reclamation)
- Long-term (post-mining and bond release).

1.3.1 Existing Hydrologic Consequences

Hydrologic impacts associated with surface mining in eastern Montana are generally understood. Previous permit applications for the Rosebud Mine have identified and discussed hydrologic consequences. In addition to evaluating the monitoring database for previously unforeseen impacts, this PHC compares and evaluates the existing hydrologic consequences to the monitoring data.

The identified hydrologic consequences from existing permits are summarized in the following subsections.

1.3.1.1 Surface Water

Due to mining operations, the surface water system will be impacted. More specifically, there will be impacts to the topography, surface water quantity, surface water quality, and erosional stability. Short-term impacts are expected during mining.

Surface Water Quantity

Potential Short-Term Impacts

As mining proceeds through the drainages, stream flow patterns will be disrupted by the mine pit and the construction of sediment control structures. During mining much of the surface and channelized flow will be captured in sediment control structures.

Potential Long-Term Impacts

As reclamation proceeds, the drainage system will be restored. All major drainages and stream channels will be constructed to approximate original drainage configurations. A tributary system will be designed and built to restore the pre-mining system of incised drainages that collected runoff and sediment from the uplands and conveyed them to the stream channels in the primary valleys. The post-mining channels and floodplains are designed to mimic the pre-mining channels' response to rainfall events. These measures are designed to eliminate long-term changes to the surface drainage system. As the mine area is reclaimed, long term effects on the drainage system are expected to be minimal.

Surface Water Quality

The surface water quality at the Mine is continually monitored to ensure that the surface water is protected. By continuing to monitor the surface water and enforcing the mine's hydrologic control plan, current and future impacts to the surface water will be minimized.

Potential Short-Term Impacts

The Mine will continue to enforce the hydrologic control plan as the mine pits advance. If needed, additional ponds, traps and MPDES points will be added to the plan to account for the additional area of disturbance.

Potential Long-Term Impacts

Reclamation actions, including topography, vegetation and soil qualities that resemble pre-mine conditions, will minimize long-term affects to the surface water quality at the mine.

Sediment Yields

By enforcing the Mine's hydrologic control plan, current and future impacts to the sediment yield will be minimized.

Potential Short-Term Impacts

The Mine will continue to enforce the hydrologic control plan as the mine pits advance which will prevent any additional sediment from leaving the site. If needed, additional ponds, traps and MPDES points will be added to the plan to account for the additional area of disturbance.

Potential Long-Term Impacts

By establishing vegetation and soil qualities that resemble pre-mine conditions and by developing the approved post mining topography (PMT), it is anticipated that long-term effects on the sediment yield will be minimal.

1.3.1.2 Groundwater

Mining will cause impacts to both the quantity and the quality of the groundwater in the mine area. Studies in the mine area have been performed to determine the intensity and

the duration of the impacts (See Section 4.0 and Attachment D and E). That section discusses impacts to groundwater quantity, groundwater quality, and groundwater wells in the immediate or adjacent areas.

Groundwater Quantity

Mining will remove the Rosebud coal aquifer and cause diminished water levels in this aquifer in the mine vicinity for the duration of mining (See Attachment E). Drawdown commonly extends laterally into unmined coal adjacent to mine pits. The degree of drawdown in unmined coal diminishes with distance from the mine pits, with the most extensive depression of the groundwater surface occurring down-gradient of the coal removal area.

A numerical groundwater model, designated as “The Rosebud Mine Groundwater Model” was developed to simulate and predict impacts to groundwater levels and flow from mining. The Rosebud Mine Groundwater Model (See Attachment D) represents groundwater conditions from baseline (premine) to current time (2012). This model is also used to predict the groundwater response from permitted mining into the future.

For this PHC, the model incorporates the additional mining proposed in the Area B AM4 Amendment to predict the groundwater response into the future from that activity. This model application (See Attachment E) is designated as the “Area B AM4 (Amendment Application 00184) Model” (a.k.a, “AM4 Groundwater Model”). Comparison of the future predictions from the baseline Rosebud Mine Model which represents currently permitted mining to predictions simulated by the AM4 Model allows for the evaluation of the incremental groundwater response from the AM4 expansion in Area B.

Following completion of reclamation, backfill water levels are expected to approximate pre-mining coal-seam water levels. The time required for the full recovery of groundwater in the backfill aquifer will vary mine wide and will exceed 50 years in most portions that are mined (See Attachment E). Although it could take considerable time, there is no reason to expect that the regional groundwater flow gradient will not eventually recover because recharge and discharge areas for the principal aquifer will not be affected by mining. The hydraulic characteristics of the spoils will facilitate storage and transmission of groundwater between the undisturbed up-gradient and down-gradient coal aquifers restoring the essential function of conveying groundwater from recharge to discharge areas. The rate and direction of flow should eventually

equilibrate to near pre-mine water table conditions.

During mining, some tributary surface flow is retained to manage water quality. Runoff from disturbed lands is retained in mine pits, sediment ponds and traps. The retention of this runoff impacts the infiltration of water from channels, such as the East Fork Armells Creek (EFAC), to the underlying alluvial aquifer. Some of the retained water infiltrates from sediment ponds located near the alluvium and recharges the alluvial aquifer. Runoff flows from areas up-gradient of mining and from undisturbed lands continue to recharge the alluvial aquifer.

Following mining and reclamation, the function of ephemeral runoff is restored to mimic the premine conditions and the postmine contribution of runoff to alluvial aquifers should be similar to premine conditions

Groundwater Quality

Groundwater quality, within the mine area, will be impacted. This has been the subject of considerable study throughout the Powder River Basin and elsewhere (Van Voast and others 1975, 1977, 1978, and 1988). TDS concentrations in backfill aquifers generally are greater than in the coal aquifers they replaced. Resaturation of backfill, primarily by lateral groundwater flow from the undisturbed coal aquifers, can be expected to result in temporary increases in TDS concentrations as a result of elevated levels of soluble salts, (primarily calcium, magnesium, sodium and sulfate) leached from the overburden. According to Van Voast and Reiten (1988), average TDS concentrations of groundwater in mine spoils in Decker area mines are 50 to 200 percent higher than the concentrations in the undisturbed coal aquifers. Locally, TDS values may be even higher. Similar geochemical conditions have also been simulated in the laboratory with bench scale column-leach and paste-extract leaching tests using overburden materials representative of those to be disturbed by mining at specific mines. Generally, the dissolved-solids concentrations in the backfill water reach a maximum during initial saturation and then decrease to an equilibrium level after one or more pore volumes of water pass through the backfill. A study suggests that dissolved-solids concentrations may decrease as water moves from the backfill into the un-mined, down-gradient coal (Clark 1995).

As re-saturation of the backfill continues, salt concentrations are expected to be extremely variable and peak at a concentration potentially two to three times that of the

baseline coal groundwater and then decline to some equilibrium value after being flushed by one or more pore volumes of groundwater. The impacts of mining will likely result in deterioration of groundwater quality within some areas of the mine backfill to a degree that will require at least temporary reclassification of the groundwater to a lower usage class.

1.4 Mining Progression

1.4.1 Present Mining Situation

Mining has occurred at the Rosebud Mine since 1975. Active mining at Rosebud Mine is presently occurring in Areas A, B and C. Figure 3B depicts the current permitted mining at Areas A, B and C.

Mining at Rosebud consists of a combination of topsoil removal, overburden removal, and coal removal. Topsoil is salvaged with appropriate mining equipment prior to overburden removal and stockpiled as necessary or hauled directly to regraded areas. Overburden is moved by the dragline and the coal is removed by means of a truck and loader operation.

1.4.2 Area B AM4 (Amendment Application 00184) Mining

The additional proposed mining under this application is shown on Figure 3A. This application provides for the proposed mining to occur from 2013 to 2026

1.4.3 Potential Future Mining

Additional potential future mining (See Figure 3A) includes:

- Application Area B-East AM4 Application 00184

2.0 PRECIPITATION AND CLIMATE

This section describes climatological data for the Rosebud Mine and vicinity. Data presented in earlier permitting efforts are updated and presented to provide a basis for evaluating hydrologic aspects of the project.

2.1 Climate

The climate of eastern Montana is classified as semiarid continental and is characterized by hot moderately dry summers, cool dry falls, cold dry winters and cool moist springs. Winter cold spells are often interrupted by periods of warmer weather. The passage of mid-latitude storm systems is typical of the climate of this area; day-to-day weather changes can be quite extreme because of the migrating systems.

At the mine, precipitation occurs predominantly as snow from about November to April. About one-third of the total annual precipitation is in the form of snow. Due to the prevailing westerly wind, the snow typically accumulates on the leeward slopes of drainage.

2.2 Climate Monitoring

Climate data are collected at the mine and also at the nearby climate station at Colstrip, Montana (241905). Figure 4 shows the location of the current climate monitoring sites. Climate data for the Colstrip station are available from the Western Regional Climate Center (WRCC). Given that the Rosebud Mine is adjacent to Colstrip, the climatic conditions at the mine are similar to that of the town. The period of record for the Colstrip station extends from March 1927 to December 2011.

2.3 Temperature

Table 1 provides the statistical summary of the climate at Colstrip. The average maximum and average minimum daily temperatures as measured at Colstrip are 88.1^{o} F in July and 9.6^{o} F in January respectively. The maximum and minimum temperatures ever recorded at Colstrip are 111° F (8/6/1961) and -50° F (2/15/1936).

2.4 Precipitation

The average annual precipitation at Colstrip is 15.17 inches. The annual precipitation

and monthly average precipitation are shown on Figure 5. The 30 year monthly precipitation data from the Colstrip weather station are provided in Attachment A (Table A-1).

Western Energy currently collects precipitation data from four rain loggers. The locations of the on-site precipitation stations are shown on Figure 4. Table 2 compares water year 2011 precipitation data from the Colstrip weather station to the data collected at four locations at the mine. Precipitation data collected at the mine are reasonably comparable to that from the Colstrip station. The Colstrip data are used in this PHC as they have a longer and more complete record.

Western Energy also collects precipitation data from 9 wedge rain gauges located at surface water monitoring sites (Figure 4). These data are reported in the Annual Hydrology Report for each water year.

2.5 Long-Term Climate

Figure 6 shows the departure from average (DFA) plot of the annual precipitation data. The DFA calculations are shown in Table A-2 in Attachment A. The DFA plot provides a qualitative representation of precipitation trends. Periods with negative values are indicative of lower than average precipitation (drought) and periods with positive values represent wetter than normal precipitation.

The uppermost plot on Figure 6 shows the precipitation trends for the period of record at Colstrip extending from 1927 to 2011. The lower plot shows the DFA for the time period from 1981 to 2011. As the plot shows, precipitation tended to be below average from about 1981 to 1990, and was about average from 1990 to 1999. This was followed by a drier period from 1999 to 2004 and it has been relatively wet since then until current (2011).

2.6 Evaporation

Annual pan evaporation data have been collected in the vicinity of the Rosebud Mine at the Huntley climate station for a period of record extending from 1911-2005 and at the Yellowtail Dam climate station from 1948 to 2005 (www.wrcc.dri.edu/htmlfiles/westevap.final.html). It is typical to apply a pan coefficient from about 0.7 to 0.8 to obtain an estimate closer to the actual evaporation from a surface water body. The average annual pan evaporation for Huntley and Yellowtail

Dam is 41.27 and 47.56 inches, respectively. Assuming a pan coefficient of 0.75 the approximate annual evaporation at the Rosebud Mine ranges from 30.95 to 35.67 inches. Most of the evaporation in the vicinity of Huntley occurs from April to September, whereas at Yellowtail Dam most of the evaporation occurs from May through October.

Potential evaporation at Colstrip exceeds precipitation. This condition is common and typical of semiarid areas with warm summers.

The amount of evaporation at the mine at any time is primarily dependent on the extent of the ponded surface area of the mine ponds. This varies from year to year, and seasonally and is dependent upon the amount of surface water runoff, and mine pit pumping that is necessary.

Another factor contributing to loss of moisture in an area is sublimation. Sublimation is a direct conversion of ice or snow to water vapor without passing through a water phase. Chow (1964) estimates sublimation losses in the middle latitudes during the winter season to be about 0.5 inches of water per month of snow cover. Snow normally occurs in the Colstrip area from November through March and accounts for approximately one-third of the total annual precipitation for the Colstrip area. Thus, during this period, sublimation could transfer about half of the precipitation (2.5 inches) occurring from November through March back into the atmosphere.

3.0 SURFACE WATER

3.1 Regional Setting

The Rosebud Mine is located within the Armells Creek and Rosebud Creek drainages which are tributary to the Yellowstone River drainage (Figure 7). Both Armells and Rosebud Creeks flow to the north and join the Yellowstone River roughly 27 miles from the mine.

3.2 Local Surface Water Regime

The drainage areas containing the Rosebud Mine are part of the Yellowstone River Basin. The total drainage area of the Yellowstone River Drainage is 69,083 square miles (44,226,000 acres) which includes flow from the Clark Fork of the Yellowstone, Bighorn, Tongue and Powder River basins. The nearest long-term downstream gaging station on the Yellowstone River is at Miles City, Montana (USGS 06309000). Discharge, reflecting a drainage area of 48,253 square miles at this station has been measured since 1922. This station is just downstream of and includes discharge from the Tongue River. Boysen Reservoir and the Yellowtail Dam on the Bighorn River and the Tongue River Reservoir provide for artificial regulation of flows above this station.

The USGS gaging station Yellowstone River at Forsyth (USGS 6295000) is located between the mouths of Armells and Rosebud Creeks. Discharges have been measured at this site since 1977.

Figures 8A and 8B show the period of record annual discharge and average monthly discharge for these Yellowstone River gaging stations. The highest seasonal discharges on the Yellowstone typically occur from mid-June through early July reflecting upstream higher elevation mountain snowmelt.

Surface water runoff from the Rosebud Mine discharges to the Rosebud Creek and Armells Creek Drainages (Figure 7). Both flow to the north and are tributary to the Yellowstone River. Rosebud Creek drains 1,302 square miles and discharge was measured at USGS Station 6296003 (Rosebud Creek at mouth near Rosebud, MT) from 1974 to 2006. The Armells Creek drainage is 370 square miles. Discharge at USGS 6294995 (Armells Creek near Forsyth, MT) was measured from 1974 to 1995. Figure 8B shows average monthly discharge for these measuring stations.

Table 3A shows the annual discharges for the time period 1975 to 2006 to allow comparison of Rosebud and Armells flows to those of the Yellowstone River. Table 3B shows the mean monthly discharges for the same stations.

As shown in Tables 3A and 3B, the Rosebud Mine drainages contribute relatively small discharges to the Yellowstone River (Armells Creek 0.06% and Rosebud Creek 0.25%). Therefore, activities at the mine are unlikely to have any measurable impact to the Yellowstone River.

The 10-year, 24-hour (1Q10) peak flows (McCarthy [USGS], 2004) (See Attachment B) for the key surface water stations are:

Station	Discharge (cfs)
Yellowstone River at Forsyth	69,100
Rosebud Creek near Rosebud	1,020
Armells Creek near Forsyth	981

These peak flows are indicative of the nature of the Armells and Rosebud Creeks response to intense precipitation events but again show limited potential for impacts associated with mining at Rosebud to the Yellowstone River.

3.2.1 Local Setting

The land surface at Rosebud Mine can be characterized by gentle slopes and subdued drainage divides. There are steeper slopes and narrow ridges present in the western portions of the area.

The numerous ephemeral tributaries at the mine, as shown on Figure 9, flow only during periods of snowmelt and/or after periods of significant rainfall. When rainfall or snowmelt exceeds the infiltration rate of soils, water flows overland and then to drainage channels. During runoff, alluvium underlying the ephemeral drainages may become saturated and then slowly drain.

Stream channels form via erosion processes in response to flow events. In upper

tributaries, stream channels are often not well defined as having distinct channel beds and banks. These undefined stream channels reflect sediment erosion and deposition processes.

East Fork of Armells Creek is the most significant tributary at the mine. The creek is ephemeral at the mine but becomes a perennial stream sourced by groundwater down-gradient of the project area in the vicinity of the Town of Colstrip. Recharge from the Castle Rock Lake reservoir, the Colstrip wastewater treatment plant, and the PPL treatment pond leakage significantly contributes to the flow in the creek downstream from the mine.

A recent field inspection of the East Fork Armells Creek showed three short segments of flowing water between Areas A and B (Figure 10). Six ponded sections were present. Most of the creek bed upstream from Area A was dry. The limited flow sections and ponded sections are generally expressions of the groundwater table. Progressing from west to east along the East Fork Armells Creek, the following is observed:

- The alluvium is bounded by overburden (upgradient of Area B).
- The alluvium then comes into contact with the Rosebud coal as the overburden pinches out (between Areas B and C to the west) (Figure 11).
- The alluvium then dissects into the Rosebud coal and into the upper portions of the interburden (from eastern portions of channel between Areas B and C, and in the western portion between Areas A and B)
- The alluvium eventually dissects into the McKay coal (eastern portion of channel between Areas A and B) (Figure 11).

In other words, the contribution of groundwater from the Rosebud coal to the alluvial groundwater increases progressing from west to east along the East Fork Armells Creek. At the very eastern edge of the Mine, the McKay coal groundwater also contributes to the alluvial groundwater. Note, however that most flow in the alluvium is dominated by upgradient alluvial sources of groundwater. In comparison, Rosebud coal and McKay coal contributions are small.

3.2.2 Local Drainages

Local drainages at the Rosebud Mine Areas A, B, and C include (Figure 9):

Drainage	Sub-Drainage	Mine Permit Area
Armells Creek Drainage	Upper West Fork Armells Creek	C
	East Fork Armells Creek	A, B, C
	Stocker Creek	A, C
	Donley Creek Black Hank Creek	C
Rosebud Creek Drainage	Lee Coulee	B
	Cow Creek	B

3.2.3 Stream Water

3.2.3.1 Flows

Surface water at Rosebud Mine flows in response to significant snowmelt or rainfall events as typical of local drainage basins in Eastern Montana. Flow patterns vary as they are dependent on precipitation patterns (e.g., wet vs. dry climate periods), the nature and intensity of precipitation and snow accumulation and snow melt, soil conditions (dry, wet, frozen, etc.), vegetative cover, slopes, natural storage and storage resulting from mining water management.

In practice, it has been difficult to measure these infrequent ephemeral flows. Continuous flow monitoring equipment is susceptible to equipment related operational issues. In particular, the Stevens Recorders, which plot water stage on circular paper charts, have not been reliable over extended times. Sites with Stevens Recorders were upgraded to utilize electronic pressure transducers and data loggers in Water Year 2012. Initial operation shows increased reliability, including during wintertime, and better data when compared to the Stevens Recorders. Additionally, measurable flows tend to occur during spring snowmelt and precipitation. At times, the resulting wet soil conditions from precipitation and snowmelt limit physical access to the monitoring sites.

Surface water flow monitoring sites are summarized in Table 4 and shown on Figure 12. The available surface water flow data reflect ephemeral flows based on precipitation driven runoff. Figures 13 and 14 graphically depict the available discharge data from surface water monitoring sites SW-55 (East Fork Armells Creek) and SW-65 (Stocker Creek), respectively. The data showed only three flow events exceeding five cfs at SW-55 and five events at SW-65 over a time period of about 28 years. Please note that there are missing flow data due to frozen conditions and equipment malfunction. It is likely that flow events occurred but are not reflected in the data.

The data shown on Figures 13 and 14 do not identify significant flows from about the late 1990s to 2009. The lack of observed flows in the data is likely a result of a combination of:

- Missing data
- Capture of tributary flows during mining
- Climatic factors (i.e., drought)

3.2.3.2 Water Quality

Water quality data for the East Fork Armells Creek, Cow Creek, Stocker Creek and West Fork Armells Creek drainages are summarized in Tables 5A through 5D. The tables show water quality statistics for baseline samples and other data. Baseline samples were isolated from the surface water quality dataset based on analysis of sampling location, sampling date and maps showing mining progression over time. Only samples collected before mining activities started upstream were considered baseline. All other samples, which include those taken after mining started up-gradient and samples for which only the drainage is known, were grouped together in 'other data'.

The data illustrate the extremely high variability of the surface water quality in these drainages, with the standard deviation of a given water quality parameter often higher than or similar to the average. This variability is to be expected given the ephemeral nature of flow in the drainages. Comparison of East Fork Armells Creek and Stocker Creek water quality parameter averages shows that in many cases baseline averages are lower. However, given the high variability of the data, as indicated by the standard deviations for water quality parameters, it is difficult to ascertain whether this increase is related to mining activities or other factors (e.g. the amount of precipitation and runoff).

Regional water quality statistics for trace elements from the Area 49 study (Slagle et al., 1983) are shown in Table 6. The extent of the Area 49 study area is shown on Figure 15. Comparison of baseline trace element concentrations in the Rosebud Mine vicinity and Area 49 samples, shows that in some cases the ranges observed in Rosebud Mine samples are larger. Again, this is likely due to the ephemeral nature of stream flow in the vicinity of the Rosebud Mine. Most Area 49 surface water quality samples were collected at locations with perennial stream flow, where the variability in stream water quality is expected to be lower.

Chromium, cadmium, lead and mercury concentrations in excess of DEQ-7 standards have been observed in baseline surface water samples. Nitrate plus nitrite nitrogen concentrations in excess of 10 mg/L were found in samples taken at SW-01, SW-65 and SW-66. SW-01 is located in the East Fork Armells Creek drainage downstream from the town of Colstrip. SW-65 and SW-66 are located in the Stocker Creek and Cow Creek drainages, respectively. One sample from SW-65 and SW-66 had nitrate plus nitrite nitrogen concentrations in excess of DEQ-7 standards.

Table 7 and Figure 16 identify MPDES discharge points at the Rosebud Mine. Water quality samples are collected in accordance with permit requirements and reported to DEQ in monthly discharge monitoring reports. In general, MPDES outfall samples for planned discharges meet the standards set forth in the MPDES permit. From water year 1999 through 2011, there were fewer than ten permit limitation exceedances during planned discharges. It is standard practice at Rosebud Mine to collect a water quality sample before a planned discharge to ensure the water will meet MPDES permit requirements. The majority of discharges occurring at Rosebud Mine are planned, with most unplanned discharges occurring from April through July during very wet years, e.g. 2011.

3.2.4 Surface Water Uses

Historically, the only known use of surface water in the vicinity of the mine has been for livestock watering. Livestock impoundments were constructed on drainages to retain ephemeral discharges for seasonal livestock use.

Currently, livestock water use continues and surface water is also used for dust suppression.

3.2.5 Impoundments

Surface water flows at the mine are controlled using impoundments to retain runoff for sediment control. Impoundments at the Rosebud Mine include sediment control structures and livestock watering ponds. Information about the impoundments in or around Areas A, B and C is summarized in Table 8. The locations of these impoundments are shown on Figure 17.

Impoundments are typically filled by surface runoff from snowmelt and precipitation. Some livestock water ponds are sourced by spring flows. There are a few impoundments on East Fork of Armells Creek where the bottom of the channel intercepts the underlying alluvial aquifer.

Most of the sediment control impoundments will be removed following mining, but a few may remain as permanent features (see Table 8).

Water quality statistics from samples collected at stock ponds are summarized in Table 9. The comparison of stock pond water quality to livestock water quality criteria is provided in Table 10. The water quality criteria for livestock are presented in Attachment C. Figure 18 shows the changes (e.g., time series) in TDS in impoundments over time.

3.2.5.1 Sediment Control Structures

During mining, surface water runoff and erosion control measures are implemented to capture runoff water for sediment control. Detailed information about specific runoff and erosion control measures is provided in Exhibit D (Approximate Hydrologic Control Plan) of the permit amendment (AM4) application.

Pits

Pits will be used to control runoff at active mining areas. Excess water will be managed in the pits, or pumped to sumps.

Ponds (Impoundments)

Sediment traps and ditches are designed to manage runoff (10-year 24-hour storm event) from spoils and disturbed areas away from active pits. Smaller traps and ditches will be used per provisions in the MPDES permit to control runoff from disturbed areas

during reclamation.

3.2.5.2 Livestock Ponds

Livestock ponds retain runoff in stream channels and discharge from springs. There are currently four dams in the EFAC stream channel within the Rosebud Mine, which retain runoff for livestock watering purposes (Figure 10).

3.2.6 Springs

Ninety springs have been identified in the Rosebud Mine area. Of these, 28 springs are located within or adjacent to Areas A, B and C. Table 11 lists and summarizes information about these springs and their locations are identified on Figure 19. Most of these springs are associated with the Rosebud and McKay coal or clinker; however, there are a few that originate from the overburden and spoils.

3.2.6.1 Spring Flow

The monitored springs in the vicinity of Area C typically seep over a broad area. Therefore flow is typically not measurable. With the exception of spring SP-76, all springs have been dry at times during the period of monitoring. One spring monitoring site, SP-66, has consistently been dry. Although no flow data are available, all monitored springs have at times discharged to ponds and available water depth data are presented in Figure 20. Most springs show seasonal variations with most ponding occurring in the spring time. No clear trends in the depth of ponded springs can be observed.

Two springs have developed in reclamation; SP-46A in Area C East and SP-112A in Area C North. Both springs seep out over an area that is only a few feet wide. At times these springs are ponded with water levels up to 0.3 feet.

3.2.6.2 Spring Water Quality

Spring water quality fluctuates and is variable. This variability in water quality and degree of mineralization was also reported in the hydrogeologic study conducted in the Colstrip area by Van Voast et al. (1977).

The water quality of monitored springs located in or near Area C is summarized in Table 12. There are no monitored springs in or near Areas A and B. TDS concentrations

below 1,000 mg/L have been observed at Rosebud coal springs SP-35 and SP-37 near the permit boundary of Area C West. Both of these springs discharge from coal seams. The highest TDS concentration of 3,950 mg/L is associated with spoils spring SP-112A in Area C.

Comparison of spring water quality data in Table 12 to that of their associated aquifers (Table15C) yields the following observations:

- The water quality of Rosebud coal springs is generally comparable to that of the baseline Rosebud coal groundwater. However, the average bicarbonate concentrations in spring water are higher compared to groundwater and the sodium and sulfate concentrations tend to be lower.

- The TDS concentrations in McKay coal spring SP-63 fall within the range of TDS concentrations reported for baseline McKay coal groundwater for Area C. The average bicarbonate concentration in the spring water is higher than in McKay coal groundwater, whereas the average sodium and sulfate concentrations are lower.

- The TDS concentrations in overburden springs fall within the range reported for baseline overburden groundwater in Area C.

- The average TDS concentration in the two spoils springs, SP-46A and SP-112A, is lower than the average TDS concentration in Area C spoils groundwater.

Figure 19 shows TDS time series plots for all monitored springs in the vicinity of Areas A, B and C for which more than two water quality samples are available. TDS concentrations are generally variable, with occasional spikes. One spring, SP-46A, shows a slight gradual increase in TDS levels during the 2000s. This spring is located next to the haul road in Area C East and is associated with spoils. The increase in TDS concentration is mainly due to an increase in sulfate concentrations. The water quality of this spring is similar to the spoils groundwater quality at this location. Comparison of water quality data from SP-46A and SP-112A with Area C spoils groundwater quality (Table 15C) shows that the spoils spring water has higher bicarbonate concentrations and lower sulfate and sodium concentrations. Similar differences were observed when comparing the water quality of springs issuing from coal seams to the groundwater

quality in the coal seams.

Water Quality Standards Exceedances

One spring sample taken from SP-35 on June 24th 2008 showed exceedances of Montana numeric water quality standards. Total mercury and dissolved mercury concentrations in this sample were 0.13 mg/L and 0.006 mg/L, respectively. More recent samples from this well showed mercury concentrations below detection limit.

Conclusion

Analysis of the existing spring water quantity and quality data showed no obvious direct impacts from mining activities on the flow and water quality of existing springs. The lack of historical spring water quality data combined with the generally high variability in water quality between springs and over time for a given spring makes it difficult to draw any definite conclusions at this point. Further sampling efforts are required to analyze possible hydrological impacts of future mining activities on the water quality of existing springs.

The data indicate that new springs may occur in spoils deposits. The water quality in these springs is projected to be similar to the quality of the groundwater in these deposits. In general, springs tend to have higher bicarbonate and lower sodium and sulfate concentrations compared to the groundwater in the stratum from which they are sourced.

3.3 Probable Hydrologic Consequences

3.3.1 Surface Water Quantity

3.3.1.1 Short Term Impacts – During Mining

Generally, surface water flow at the mine is ephemeral and it is dominated by short-term/episodic precipitation and snowmelt runoff events. In a few instances in EFAC, limited intermittent flow has been observed. However, such intermittent flows are typically associated with the presence of immediately up-gradient ponds or ponded conditions. Figure 10 shows that there are currently four dams on the EFAC. In effect, it is apparent that the intermittent flow conditions are artificially induced by the presence of the ponds that act to temporally store surface water runoff which in turn seeps or infiltrates into the underlying alluvium. This leads to a localized increase in the water table which in turn manifests itself in some instances as the limited intermittent flow that is sometimes observed in EFAC.

During mining, the alluvial groundwater levels may become depressed when mine dewatering occurs in the vicinity of alluvium. If those groundwater levels intercept the thalweg and lead to intermittent flow, then those intermittent flows could be affected or reduced accordingly. An example of water level changes in association with mine dewatering can be ascertained from Figure 21 which shows water level changes in selected East Fork Armells Creek alluvial wells. The figure shows that alluvial groundwater levels tend to decline when mining activities are closest to the alluvial wells. For example, mining closest to well WA-114, which is located between Area A and B, was conducted in 1984 and the graph shows a decline in water level between 1980 and 1985. Water levels in the two alluvial wells (WA-209 and WA-104) between Areas B and C show a more gradual decrease. Note also that some of the water level changes (e.g., prior to 1992) are most likely due to changes in climate.

When the Area B Permit was written in 1986, the East Fork Armells Creek was described to possess two short segments respectively within Sections 8 and 15 (T1N, R40E) which had continuous base flow during much of the year ranging from no flow to about 30 gpm. A recent field survey (Section 3.2.1) of EFAC showed no flow in Section 15. The previous PHC (WECo, 1986) described the source of the flow as alluvium with possible contribution of the Rosebud coal in Section 15. Given the decreased water levels in alluvial wells between Areas B and C, it is possible that the change in flow is a

result of mine related dewatering. With regard to Section 8, alluvium in that vicinity is bounded by overburden and this alluvium is most likely hydraulically isolated from the Rosebud coal being mined. Hence, it is deemed as unlikely that any declination of flow in EFAC at this location is a result of mining. Rather, it is associated with presence or absence of stored surface water in the rather sizeable pond observed in Section 8 which captures water from the ephemeral runoff events.

Ephemeral flow from lateral tributaries into the EFAC will be affected by mining as flow from such tributaries is detained by sediment control ponds. Hence, some temporal flow will not reach to the EFAC alluvium. As a result, recharge in the alluvium will be reduced. However, there would be some recharge in the vicinity of the sediment control ponds. The degree that "natural" recharge would be offset by recharge from the sediment ponds cannot be quantified.

Another mining-induced factor affecting alluvial groundwater levels, which in turn may affect surface water flows, is associated with the Mine's MPDES discharges. Mine staff report that even relatively large discharges are observed to infiltrate from the channel to the alluvium over relatively short distances and time periods. Hence, this infiltration acts to recharge the underlying alluvial groundwater which in turn causes increased water levels.

Given that there are non-mining factors affecting the alluvial water level observations (e.g., climate and pre-existing ponds), it is sometimes difficult to differentiate mining induced observations from those associated with non-mine factors. Climatic factors such as periods of drought and high precipitation influence alluvial groundwater levels, which in turn may impact surface water flows. In general, groundwater levels decline in response to drought and then increase upon wetter climate. The groundwater levels changes in WA-118 upstream from Area B and C (Figure 21) are most likely in response to climatic factors.

3.3.1.2 Long Term Impacts – After Mining

No long term impacts on surface water flow are expected to result from mining activities. Following mining, the disturbed lands are reclaimed and tributary surface runoff is no longer detained. As the main-stem channels (e.g., EFAC) are not significantly physically disturbed (e.g., not mined out), runoff reaching the channel will infiltrate to the alluvium similar to premine conditions.

Tributary drainages will be restored during reclamation and flow patterns reestablished, including incised drainages that collect runoff and sediment from uplands and transport these to the primary drainages. Reclamation revegetation will mimic premine conditions and provide for similar surface runoff rates and volumes.

The tables presented in Attachment G compare the pre and postmine geomorphology, drainage basin characteristics, and runoff. These evaluations demonstrate that the postmine surface water flows will be essentially the same when compared to premine, as the reclamation will result in similar geomorphic and hydraulic characteristics.

Ephemeral flows, which are infrequent and occur in response to precipitation events and snowmelt, are mainly influenced by climate. More specifically, the ephemeral flows reflect the nature of the snow accumulation and melt and higher intensity precipitation events. These factors are independent of mining activities and these surface water flows should be essentially the same as premine upon completion of reclamation.

Following mining, it is projected that alluvial groundwater will return to pre-mine levels. This is demonstrated by referring to Figure 21 which illustrates that alluvial groundwater levels between Areas A and B are recovering as mining moves further away. In the case of well P-04, which has the longest period of record, and wells WA-101, WA-128 and WA-124, water levels have increased slightly above initial measurement levels. This may be a result of the previously described factors (e.g., MPDES discharges) that led to increasing alluvial groundwater during mining.

Given that the alluvial groundwater levels will recover, the pre-mine conditions that led to the intermittent flow reaches before mining commenced will be re-established.

3.3.2 Surface Water Quality

As noted previously, tributary flows are intercepted during mining. Implementation of the hydrologic control plan as mining progresses will minimize current and future impacts to surface water.

During mining, sediment control measures, including pits, sediment ponds, etc. will protect water quality at the primary drainages such as East Fork Armells Creek. Planned and unplanned discharges will occur in compliance with mine MPDES discharge permit requirements.

Long-term surface water quality will return essentially to pre-mine conditions. Reclamation revegetation will control erosion and protect water quality.

The comparison of premine to postmine geomorphology, drainage basins, and runoff provided in Attachment G shows that the postmine hydrology is essentially the same as premine. When combined with reclamation revegetation, the postmine water quality will be similar to premine.

Generally, the quality of the surface water at the Mine is highly variable, due to the nature of the flows. As such, statistically significant correlations of changes in surface water quality to mining were not observed. It should be noted that continued monitoring, data collection and evaluation will allow identification of trends should they occur.

As discussed in the Section 4.0 (Groundwater), the alluvial groundwater quality shows potential impacts from mining. Changes in alluvial groundwater quality have potential to negatively impact surface water quality.

3.3.3 Springs

Evaluation of spring monitoring data does not result in the identification of changes in water quality or water quantity associated with mining. Continued monitoring will allow ongoing evaluation of changes to spring water quality and quantity.

Observations show new springs may develop in reclaimed areas. The water quality of these springs is similar to the spoils water quality at that location.

3.3.4 Erosion and Sediment Yield

Water quality is protected by the implementation of hydrologic control plans to intercept and treat storm water discharges. The comparison of premine to postmine geomorphology, drainage basins, and runoff that is provided in Attachment G shows that postmine hydrologic function will be very similar to premine. When combined with the revegetation of disturbed lands, the mine reclamation will result in similar erosion and sediment yield to premine conditions.

4.0 GROUNDWATER

4.1 Regional Setting

The Rosebud Mine is located in the northern portion of the Powder River Basin. Regional hydrology is reported in the USGS Area 49 Hydrologic Investigation (USGS, Slagle et al., 1983).

4.1.1 Regional Hydrogeology

Principal geologic units include the Fort Union Formation, Hell Creek Formation, Fox Hills Sandstone and Bearpaw Shale., Coal beds are generally found in the Tongue River Member of the Fort Union Formation. On a regional basis, the majority of water use is from alluvium and Tongue River consolidated deposits. The alluvial groundwater tends to flow in relation to surface topography towards streams and drainages. In deeper aquifers, groundwater tends to flow to the north and towards the Yellowstone River.

4.1.2 Regional Water Quality

Slagle (1983) reports that groundwater at depths greater than 200 feet is generally dominated by sodium and bicarbonate with TDS concentrations ranging from 400 to 5,700 mg/L (average of 1,400 mg/L).

Shallower water from recharge areas is characterized by higher TDS concentrations with averages ranging from about 1,500 to 2,000 mg/L.

Generally, these concentrations result in the classification of the groundwater as Class II or Class III, which may limit use for human consumption and some irrigation.

4.2 Mine Area Hydrogeology

4.2.1 Geology

The Tongue River Member of the Fort Union consists of fine-grained sandstone with thinner interbeds of yellowish brown, orange, or tan siltstone; light-colored mudstone, and clay; and coal beds. The sandstone tends to be massive or cross-bedded. The main coal beds and adjacent consolidated strata of interest for the given project are part of this member.

The specific hydrogeologic units include components of the Tongue River Member and these units are designated as:

- overburden
- clinker (generally contiguous with coal strata)
- Rosebud coal
- interburden
- McKay coal
- sub-McKay

Another key geologic feature found within the footprint and the vicinity of the Rosebud Mine includes unconsolidated alluvium.

Figure 11 illustrates the key hydrogeologic units and the mining process.

4.2.2 Local Hydrogeology

Groundwater at the Rosebud mine occurs in shallow alluvial and colluvial deposits found in drainage bottoms and in Fort Union Formation consolidated deposits as discussed below:

4.2.2.1 Alluvium

The unconsolidated geologic deposits of main hydrologic interest in the immediate vicinity of the Rosebud Mine are of Quaternary age and consist of alluvium and colluvium. The main water-bearing unit is the alluvium which can vary widely in thickness being generally less than 15 feet but it can be up to 35 feet in some areas (Vuke, et al 2001). Water-bearing alluvial deposits are present in the main drainages transecting the Rosebud Mine area which includes East Fork Armells Creek and its tributaries (refer to Figure 9). The most transmissive alluvial aquifer sequence adjacent to the Rosebud Mine is likely contained in the main stem of East Fork Armells Creek where it is bounded by Area C to the north and Areas B and B-extension to the south.

Water bearing zones of interest in the permit area are the Rosebud overburden and Rosebud coal. The alluvial aquifer associated with East Fork Armells Creek will be disturbed by mining along a short distance of the upper terrace parallel to East Fork

Armells Creek in Sections 10 and 15 (T1N, R40E). Major changes in ground water storage in the East Fork Armells Creek alluvium, however, are not expected and will not be considered here. Mining will disturb the West Fork Armells and Stocker channels in the upper reaches of the watershed. During mining, infiltration and discharge from sedimentation ponds and mine pits should mitigate the disruption of the headwater drainages. Impacts of disrupting the thin and discontinuous alluvium in Upper West Fork Armells and Stocker Creeks will have little effect on alluvial water levels downstream of the mining areas.

4.2.2.2 Clinker

Clinker deposits are red, pink, orange, black, and yellow, very resistant metamorphosed sandstone, siltstone, and shale of the Fort Union Formation. Bedrock was baked by natural burning of underlying coal, and collapsed into voids created by the burning. Clinker thickness ranges from as little as 10 feet up to 300 feet (Vuke, et al, 2001). From a hydrogeologic perspective these deposits are very permeable. Generally, the saturated thickness of clinker deposits at the Rosebud Mine is very limited. Groundwater that is present in these deposits at the Rosebud Mine tends to be perched water which is generally hydraulically isolated from the underlying strata.

Clinker is also relevant as portions of it are present in alluvial deposits. Owing to the relatively coarse nature of this clinker, the transmissivity of the alluvial deposits tends to be much higher when compared to the consolidated stratum that bounds the alluvium.

4.2.2.3 Rosebud Coal/Interburden/McKay Coal

The overburden, Rosebud Coal, interburden, and the McKay Coal (and sub-McKay) are all strata from the Tongue River Member of the Fort Union Formation. The Tongue River Member can be as thick as 540 feet. These units yield low quantities of water but at sufficient rates to provide domestic and stock well water supplies. Low yield springs also occur at outcrops from these deposits and they are frequently used for stock water supply purposes.

In the immediate vicinity of the mine, the alluvium, overburden and the Rosebud Coal are the strata most directly affected by the mining process.

4.2.3 Hydraulic Properties

Groundwater levels have been monitored at Rosebud since 1974. Table 13 lists and Figure 22 shows the locations of groundwater monitoring sites in Areas A, B and C. Monitoring wells are classified according to hydrostratigraphic units including:

- Alluvium
- Overburden
- Spoils
- Rosebud Coal
- Interburden
- McKay Coal
- Sub McKay

Figure 23A depicts simulated groundwater levels prior to mining in Areas A, B, and C. Figure 23B shows an interpretive potentiometric map based on current monitoring well data.

Hydrographs for Rosebud Mine monitoring wells are shown in Figures 5 through 14 of the Rosebud Mine Ground-Water Model Report found in Attachment D. The report contains a detailed review of well water level data collected by Western Energy up to 2011. The following is a summary of the analysis of well hydrographs in the Rosebud Mine area:

- Alluvial well water levels seem to be influenced mainly by climatic factors. Some wells in the East Fork Armells Creek alluvium appear to have responded to dewatering/mining activities in nearby areas.
- The majority of overburden wells have not been responsive to nearby mining activities. Wells that have responded are located very near active high walls.
- The response of Rosebud Coal wells to nearby mining has been variable. Wells that are most responsive are located relatively near mine pit high walls.
- The majority of interburden and McKay Coal wells have not responded to nearby mining activities. Exceptions are wells located very near active high walls.
- In general, water levels in most non-dry spoil wells have been increasing, with

the most dramatic increases in wells in the vicinity of the East Fork Armells Creek.

- The radius of influence of mining activities on water levels seems to be relatively greater in areas south of Area B and Area B extension. This observation can be explained by the degree of confinement of the Rosebud Coal and underlying strata. Southern portions of the mine tend to be more confined than the northern portions.

Figure 24 shows example hydrographs from the Montana's Groundwater Information Center (GWIC). The hydrographs illustrate drawdown in the Rosebud and McKay Coal wells, recovery in the spoils wells and seasonal influences in alluvial wells. A more in depth discussion of the predicted magnitude of the drawdown response to mining is presented in section 4.3.1.

4.2.4 Groundwater Quality

4.2.4.1 General Water Quality Evaluation

The 1983 Slagle Area 49 study provides some regional baseline groundwater quality data. Slagle data are summarized in Table 14 and provide a reference to pre-mine conditions.

Table 13 summarizes and Figure 22 shows the locations of groundwater monitoring points at Rosebud Mine. Tables 15A, 15B, and 15C provide statistical summaries of groundwater quality by hydrogeologic unit for mine Areas A, B and C, respectively. A sample is considered to represent baseline conditions if it was collected before mining approached within 0.5 miles. There were only three overburden samples (in Area A) and no interburden and sub-McKay samples meeting this criterion, as mining started in 1975. Table 16 shows the statistical water quality summary of the alluvium.

Review of the data shows that the groundwater quality varies significantly depending on mine area and geologic stratum. An example of this is the groundwater in the overburden and Rosebud coal in Area C as compared to Areas A and B. The average TDS and sulfate concentrations are lower in the Areas A and B overburden and Rosebud coal.

In Area A, with the exception of sodium, the average major ion concentrations and the TDS concentration in the spoils is higher than in the overburden after mining. The

standard deviations and range between minimum and maximum values in Area A is high, with exception of those of the sub-McKay samples.

In Area B, the average major ion concentrations and the TDS concentration in the spoils is higher than in the overburden baseline. Initial comparison of baseline average data with average after mining data indicates that interburden, McKay and sub-McKay groundwater quality is not affected by mining. Rosebud groundwater quality may be affected. Additional analysis is performed below to better characterize the nature of potential impacts.

In Area C, the average major ion concentrations and the TDS concentration in the spoils is higher than in the overburden baseline. Comparison of baseline average data with average after mining data indicates that McKay and sub-McKay groundwater quality is not affected by mining. Rosebud coal and interburden groundwater quality may be affected. Additional analysis is performed below to better characterize the nature of potential impacts.

4.2.4.2 Detailed Groundwater Quality Evaluation

Total Dissolved Solids

To evaluate changes in water quality over time, time series graphs of total dissolved solids concentration (TDS) were created for all wells in Areas A, B and C for which more than two data points are available and for all Area D and E spoils wells. The concentration of TDS was used as an indicator compound for water quality.

TDS is the main water quality indicator parameter used in several hydrogeological studies in the area (Van Voast et al. 1988, Van Voast et al. 1977). The TDS concentration is an indicator of the degree of mineralization of the water. The major chemical constituents in the groundwater in the Fort Union Formation and other shallow aquifers in southeastern Montana are: calcium, magnesium, sodium, sulfate and bicarbonate. They comprise typically more than 97% of all dissolved constituents in the groundwater. Carbonate, potassium and chloride are also common, but usually in very low concentrations (Van Voast et al., 1988).

The quality of groundwater in the Colstrip area is a product of salt dissolution and, to a lesser degree, cation exchange. Salts are produced in recharge areas by weathering and oxidation and are then dissolved by percolating groundwater. Groundwater in

recharge areas is characterized by relatively higher calcium, magnesium and bicarbonate concentrations (see also Area 49 report). Salt dissolution in the Colstrip area typically results in increased sulfate concentrations as groundwater percolates, whereas cation exchange in the Colstrip area can increase sodium concentrations with depth (Van Voast et al., 1988).

TDS is generally linearly correlated to the specific conductivity (SC) of the water. Figure 25 shows a plot of TDS versus SC and illustrates this linear correlation. Specific conductivity is also used for classification of the groundwater in beneficial use classes (Table 17).

The analyte TDS is the main indicator of water quality. Time series for the other major ions concentrations listed in Tables 15A through 15C and Table 16 were created when upward trends in TDS were observed. TDS time series graphs for different hydrogeologic units are presented in the following figures:

- Figure 26: selected overburden, McKay coal and sub-McKay wells
- Figures 27A through 27E: Area A, B and C Rosebud coal wells
- Figures 28A through 28E: Area A, B and C interburden wells
- Figures 29A and 29B : Area A, B, C, D and E spoils wells
- Figures 30A through 30C : East Fork Armells Creek alluvial wells
- Figure 31: Stocker Creek alluvial wells
- Figures 32A and 32B : West Fork Armells Creek alluvial wells

The following sections provide a detailed discussion of changes in water quality for each hydrogeologic unit, using TDS as the indicator parameter.

Overburden

TDS time series graphs for all Area A, B and C overburden wells were generated using the Rosebud Mine Water Monitoring Database. Well locations in relation to mining progression over time were analyzed when the time series graph showed increasing TDS concentrations. This evaluation showed that, in general, the water quality in overburden wells has not been impacted by mining. Two exceptions are (see Figure 26):

- WO-162, located south of mining activities in Area B, shows increased TDS

concentrations in recent years. The increase in TDS concentration is mainly due to increased sulfate concentrations. The hydrograph for this well shows decreasing water levels starting in 1998. At this time mining was occurring about 0.25 miles from this well. The recent change in TDS concentrations in this well may be influenced by water level changes as a result of nearby mining activities.

- WO-165, located in Area C, showed an increase in TDS concentrations before it was mined out in 1999. The increase in TDS concentration was mainly due to increases in sulfate, magnesium and bicarbonate concentrations. The hydrograph for this well shows decreasing water levels starting in 1993. The changes in TDS concentrations in this well may be attributable to changing water levels as a result of nearby mining activities.

The evaluation of water quality time series of overburden wells generally shows that overburden water quality has not been impacted by mining.

Rosebud Coal

Figures 27A through 27E show time series graphs for TDS in Rosebud coal wells in Areas A, B and C.

Area A

Time series for wells WR-110, WR-111, WR-105 and WR-130 show no trends in TDS concentrations. Well WR-104 shows slightly elevated TDS concentrations for the most recent sampling years. This could be explained by the proximity of WR-104 to a mining pit and the relatively high precipitation during these latter sampling years.

TDS concentrations in well WR-127 are relatively higher than for the other Rosebud coal wells and show a gradual increase over the sampling period. The increase in TDS concentrations is due to an increase in all major ions concentrations. The well is located about 250 feet south of Area A spoils in close proximity to spoils well WS-113. TDS concentrations in spoils well WS-113 have increased from 3,500 to about 4,500 mg/L (Figure 29A). TDS concentrations in WR-127 increased from about 2,500 to about 4,000 mg/L. It is possible that the increase in TDS concentrations in the Rosebud Coal well is a result of spoils groundwater flowing into the coal at this location.

Area B

The TDS concentrations in about half of the wells in Area B have remained constant. The following wells show variable TDS concentrations:

- Well WR-124 shows a spike in 1985 and higher TDS concentrations in the two most recent samples. Since mining closest to this well occurred in the late 1990s, the spike is most likely not related to mining. Since the well is up-gradient from mining activities, the more recent increase is likely due to natural causes not related to mining.
- Well WR-116 shows a spike in TDS concentration in 1983. Since mining in the vicinity of this well did not start until the mid-1990s, the spike is most likely not related to mining.
- Well WR-164 shows an increase of TDS concentrations from 1987 to 1997. Since mining up-gradient from this well did not start until 1999 this increase is most likely not related to mining.
- Well WR-160 shows an increase in TDS concentrations from about 1980 to 1990. This increase occurred for all major ion concentrations with the exception of chloride. Mining north of the well occurred in the early 1980s and more recently since 2004. The hydrograph of this well shows a decrease in water level for both periods of mining, with a recovery period in between. It is likely that the groundwater quality in this well is influenced by changes in water level as a result of mining.
- Wells WR-205 and WR-207 are located adjacent to Area B spoils dating from the early 1980s. Well WR-205 shows variable TDS concentrations ranging from about 2,000 to about 3,000 mg/L. The limited data available for well WR-207 show slightly higher TDS concentrations. Hydrographs for both wells show seasonal variations of water levels for both wells. Spoils groundwater sampled from well WS-184, located about 400 feet from well WR-207 shows TDS concentrations ranging from about 1,500 mg/L to 2,500 mg/L (Figure 29A). Alluvial wells in the vicinity (WA-101 and WA-139) show highly variable TDS concentrations between about 350 and 2,500 mg/L (Figure 30B). Variable TDS concentrations in these Rosebud Coal wells could be influenced by TDS concentrations in both alluvial and spoils groundwater, however the variability of TDS concentrations suggests that alluvial groundwater may be more responsible.

Area C

With a few exceptions the TDS concentrations in Rosebud coal wells in Area C are relatively constant. The following wells have variable TDS concentrations:

- Well WR-103 is located up-gradient from mining activities near the East Fork Armells Creek. TDS concentrations in this well have generally decreased from about 6,500 and 3,500 mg/L. Because of its location, this change in TDS concentration is not likely related to mining activities.
- Well WR-121 shows a gradual increase in TDS concentrations from about 1980 to 1990, followed by a gradual decrease from 1997 to 2006. Mining northwest of this well started in 2000 and has progressed closer since then. A hydrograph of the well shows the water level has decreased in this well since 2000, likely as a result of the dewatering associated with mining activities. It is possible that the recent change in TDS concentrations is influenced by the change in groundwater levels associated with mining.
- Well WR-126 shows a considerable increase in TDS concentrations from about 2,000 to over 8,000 mg/L. The increase in TDS is caused by an increase in all major ion concentrations. Mining immediately up-gradient from this well occurred from about 1984 onward. No spoils groundwater quality data are available in the vicinity of this well, however since a potentiometric map (Figure 23B) shows that the well is located downstream from the spoils, the increased TDS concentration might be due to spoils groundwater flowing into the Rosebud coal aquifer.
- Well WR-169 shows a sharp drop in TDS concentrations in 1990, followed by a gradual increase in TDS until the well was mined out in 2000. Mining in the vicinity of the well started in 1990. A hydrograph of the well shows a drop in water level due to dewatering associated with mining starting around 1990, followed by a partial recovery as mining activities progressed further away. As was the case for WR-121, the decrease in water level was associated with a drop in TDS concentrations. Similarly, the partial recovery occurred at the same time as the gradual increase in TDS concentration.

Interburden

Figures 28A through 28E show time series graphs for TDS in interburden wells in Areas A, B and C.

Area A

Two wells in Area A show increases of TDS concentration in the interburden groundwater:

- The TDS concentration in well WI-111 decreased in the early 1980s and then increased again to the same level in the late 1990s. Mining south of the well occurred in the late seventies and mining west of the well occurred from the late 1980s to 2000. The hydrograph shows increasing water levels from about 1985 to 2000. It is likely that the changes in TDS concentrations in this well are a result of changes in water level. However, it is not clear if changes in water level are due to climate or a result of mining activities.
- Well WI-102 shows a gradual increase in TDS concentrations from about 2,000 to about 3,000 mg/L, with spikes around 3,500 mg/L. This increase in TDS is a result of increases of all major ion concentrations. The well is located at the edge of Area A spoils adjacent to spoils well WS-106. The TDS concentrations in spoils groundwater from WS-106 have remained relatively constant at about 3,000 mg/L (Figure 29A). It is likely that the increase in TDS concentrations in well WI-102 groundwater is influenced by TDS concentrations in spoils groundwater. However given the relatively constant TDS concentration measured at WS-106, it is not expected that the TDS concentrations at WI-102 will continue to increase.

Area B

The following wells in Area B show increases in TDS concentrations in the interburden groundwater:

- Well WI-157 is located in Area B spoils and adjacent to spoils well WS-157. TDS concentrations in the interburden groundwater from this well show a slight increase from 1,300 to about 2,000 mg/L. This increase in TDS concentration is due to increases in calcium, magnesium and bicarbonate concentrations. As discussed earlier, higher concentrations of these ions are typically associated with recharge areas. TDS concentrations in the spoils groundwater at this location have remained relatively constant at 2,500 mg/L and the average TDS concentration in the closest alluvial well (WA-125) is 2,245 mg/L. The hydrograph for well WI-157 shows a gradual water level increase of over 30 feet at this well during the sampling period. Comparison of water levels in this well to those in the closest alluvial well shows that the interburden is likely being recharged by the alluvial groundwater in this area.

The increase in TDS concentrations in the interburden groundwater at this location is likely largely due to inflow of alluvial groundwater and possibly to a lesser extent the overlying spoils groundwater.

- WI-159 is located in Area B spoils adjacent to spoils well WS-159. TDS concentrations in the interburden groundwater from this well have increased from about 2,500 to 4,500 mg/L. The increase in TDS concentration in this well is mainly due to increases in sulfate and magnesium concentrations. The TDS concentration in the spoils groundwater at this location has increased from about 3,800 to 4,300 mg/L. It is possible that the increase in TDS concentrations in the interburden groundwater at this location is influenced by TDS concentrations in the overlying spoils.
- Well WI-160 is located south of Area B spoils and adjacent to Rosebud coal well WR-160. TDS concentrations in interburden groundwater at this location increased slightly from the early 1980s to the early 1990s and have remained relatively constant since then. A similar increase was seen for the adjacent Rosebud coal well WR-160. The hydrograph of WI-160 shows decreases in water level for two periods of mining, with a recovery period in between. It is likely that the groundwater quality in this well is influenced by changes in water level as a result of mining.
- Well WI-184 is located in Area B spoils adjacent to spoils well WS-184. TDS concentrations in both the interburden and spoils groundwater at this location have increased from about 1,500 to about 2,350 mg/L. The increased TDS concentration is due to an increase in all major ion concentrations with the exception of bicarbonate. It is likely that TDS concentrations in the interburden groundwater at this location are influenced by TDS concentrations in the overlying spoils.
- Well WI-164 is located adjacent to Rosebud coal well WR-164 and south of current mining activities. Comparison of time series graphs for both wells show that TDS concentrations in WI-164 are very similar to TDS concentrations in WR-164. As was discussed earlier these changes are not likely related to mining activities.

Area C

The following wells in Area C show increases in TDS concentration in the interburden groundwater:

- Well WI-153 is located adjacent to Rosebud coal well WR-126 and north of

Area C spoils. No water quality data are available for WS-122; the closest spoils well located about 600 feet south of WI-153. TDS concentrations in interburden groundwater at this location increased from about 1,500 mg/L to about 2,500 mg/L in the 1980's when mining activities were occurring in the vicinity of the well. This increase was observed for all major ion concentrations with the exception of bicarbonate. Since this increase, TDS concentrations have remained relatively constant. It is possible that the increase in TDS in the 1980's is related to mining activities occurring up-gradient from this well.

- Well WI-181 is located adjacent to Rosebud coal well WR-181. The two most recent interburden groundwater samples at this location showed an increased TDS concentration. Since this well is located up-gradient from mining activities, this increase is not likely related to mining activities.
- Well WI-186 is located in Area C spoils adjacent to spoils well WS-186. No spoils water quality data are available in the vicinity of this well. From 1995 to 2007 the TDS concentration in the interburden groundwater at this location increased considerably from about 500 to 4,670 mg/L (2007). This change is due to increased concentrations of chloride, sulfate, magnesium and calcium. Mining in the immediate vicinity of this well started in 1984. It is possible that the increase in TDS concentrations in this well is due to infiltration from spoils groundwater.
- Well WI-180 is located in the western corner of the permit boundary in Area C and shows considerable variations in TDS concentration. Since mining activities in this area did not start until 2008, these variations are likely caused by natural processes not related to mining.

McKay coal

TDS time series graphs for all Area A, B and C McKay coal wells were generated using the Rosebud Mine Water Monitoring Database. Well locations in relation to mining progression over time and well logs were analyzed when the time series graph showed increasing TDS concentrations. This evaluation showed that, in general, the water quality in McKay coal is not impacted by mining. However, there are a few instances in which McKay coal wells showed upward trends in TDS that could be related to nearby mining activities (see Figure 26):

- Groundwater from WM-106, located in Area B, showed an increase in TDS concentrations before the well was mined out. The increase in TDS in the

McKay groundwater at this location may be influenced by upgradient mining activities. The log for well WO-106 indicates that the interburden at this location is relatively thin at approximately 17 feet.

- WM-157 is located in Area B spoils just south of the EFAC and is paired with WI-157 discussed earlier. TDS concentrations in this well increased slightly before it was abandoned. The log for this well shows an interburden thickness of 16 feet. It appears that the increase in TDS concentration in McKay groundwater at this location is due to flow through the interburden.

- Groundwater from WM-161, located in Area B, showed an increase in TDS concentrations before the well was mined out in 2002. The increase in TDS in the McKay groundwater at this location may be influenced by upgradient mining activities. The log for well WM-161 indicates that the interburden at this location is relatively thin, at approximately 20 feet.

- WM-184 is screened in the McKay coal beneath Area B spoils just south of the EFAC alluvium and is paired with interburden well WI-184 discussed previously. In recent years the TDS concentration in the McKay groundwater at this location has increased to about 1,500 mg/L. The log for this well indicates an interburden thickness of 40 feet at this location. However, the interburden just north of this well may be truncated by alluvium, resulting in a smaller effective thickness of the interburden in proximity of WI-184. It appears that the recent increase in TDS concentrations in WM-184 is due to infiltration from the interburden groundwater at this location.

- WM-186 is screened in the McKay coal beneath Area C spoils and is paired with spoils well WS-186 and interburden well WI-186. The TDS concentration in the McKay groundwater at this location has increased to from about 500 mg/L to a maximum value of about 2,500 mg/L. The log for this well indicates an interburden thickness of about 24 feet at this location. It appears that the increase in TDS concentrations at this location is due to infiltration from interburden groundwater at this location.

The detailed evaluation of water quality time series of McKay coal wells shows that, in general, McKay coal groundwater quality has not been impacted by mining activities.

Exceptions seem to occur in areas where the thickness of interburden separating the Rosebud coal or spoils and McKay coal is thin. In these areas the McKay coal groundwater seems to be more vulnerable to impacts from mining.

Sub-McKay

TDS time series graphs for all Area A, B and C sub-McKay coal wells were generated using the Rosebud Mine Water Monitoring Database. Well locations in relation to mining progression over time and well logs were analyzed when the time series graph showed increasing TDS concentrations. In general, there are no changes in sub-McKay groundwater quality as a result of mining activities. The analysis isolated one well showing an increasing TDS trend that could be due to by nearby mining (see Figure 26). Well WD-186 is paired with McKay coal well WM-186 discussed above. Both wells show similar increases in TDS concentrations. It is likely that the same geologic factors increasing the vulnerability of McKay groundwater to impacts from mining also contribute to the vulnerability of sub-McKay groundwater.

Spoils

Time series graphs for TDS concentrations in spoils wells are shown on Figures 29A and 29B. With a few exceptions, spoils groundwater contains substantially higher TDS concentrations than does groundwater in undisturbed aquifers. Tables 15A through 15C show that the constituents that comprise most of the changes are sodium, calcium, magnesium and sulfate. Figures 29A and 29B show that the water quality in the new mine spoils is highly diverse with TDS concentrations between 1,000 and 9,000 mg/L.

Time series graphs show that TDS concentrations in most spoils wells vary over time. This attests to the newness of the spoils and their poor chemical equilibrium with recharge water (Van Voast, 1988). Figures 29A and 29B show the following types of time series graphs:

- Decreasing trend (e.g. WS-112), which occurs when salts are leached by groundwater more rapidly than they are replenished by recharge.
- Increasing trend (e.g. WS-100), which occurs when soluble weathering products are introduced more rapidly than they can be flushed from the system.
- Variable (e.g., WS-114), which can occur when TDS varies as a result of water level changes. This is more likely to happen when the groundwater flow rate

is slower and if recharge rates are less.

- Stable (e.g. WS-106), which may attest to the establishment of some degree of equilibrium.

Alluvium

East Fork Armells Creek Alluvium

Within the Rosebud mine the East Fork Armells Creek bed is located between mine Areas A and B, and B and C. The alluvium in this area consists of sand and gravel beds overlain by beds of silt and clay. The thickness of the alluvium can be as high as 40 feet. Groundwater flow in the alluvium of the East Fork Armells Creek is almost parallel to the watercourse. Recharge of the alluvium occurs vertically by streamflow and precipitation and laterally from other aquifers (Van Voast et al., 1977).

Between Areas A and B, near alluvial wells P-03, P-04 and P-05, the alluvial gravel cuts into the McKay coal, and as a result, the gravel in this area is recharged directly by the McKay coal (see also Section 3.2.1). Before mining started in this area, the alluvial groundwater at this location was chemically very similar to the McKay coal groundwater. Alluvium is also recharged indirectly by water from the Rosebud coal subcrop and the stream channel (Van Voast et al., 1977). Nearby mining activities which are usually associated with dewatering can temporarily cause the recharge from the Rosebud coal to cease. After mining activities have ceased and groundwater levels reach equilibrium, indirect recharge from the spoils might impact alluvial groundwater quality at this location.

Between Areas B and C, in the vicinity of alluvial well WA-122, the alluvial gravel lies on top of the Rosebud coal. Upstream from this location, the alluvium is isolated from the Rosebud coal by the overburden. Recharge from the overburden, which is characterized by much lower hydraulic conductivities compared to the Rosebud coal, is expected to be relatively small in these areas. As a result, it is expected that mining activities will not impact the water quality of the alluvial groundwater at this location.

Between the two cross sections described above, the potential impact of mining activities on the alluvial water quality is expected to increase gradually moving downstream along the East Fork Armells Creek alluvium.

Figures 30A, 30B and 30C show TDS concentrations for alluvial wells along the East

Fork Armells Creek. Table 16 gives an overview of the water quality statistics for the drainages of concern. Water quality statistics for East Fork Armells Creek are separated by location: upstream, between Areas B and C, between Areas A and B, and downstream from the mine. TDS concentrations in wells up-gradient from mining activities are relatively constant with an average value of 1,864 mg/L. Within the mine area, TDS concentrations area are more variable, with average TDS concentrations of 2,544 and 2,784 mg/L, between Areas A and B, and B and C, respectively. The highest TDS concentrations are observed in alluvial groundwater near the town of Colstrip. The average TDS concentration downstream from the mine is 4,084 mg/L. Evaluation of water quality in wells around Colstrip is outside the scope of this PHC.

General analysis of the available TDS time series and well hydrographs shows that alluvial water quality is likely impacted by mining activities. Examples of processes that might cause TDS concentrations in alluvial groundwater to change are explained below.

- After conclusion of mining activities, overburden material is backfilled and spoils water levels typically show a gradual increase until they reach equilibrium. If alluvial water levels in the vicinity of the spoils are lower than the spoils groundwater levels, spoils groundwater could be flowing into the alluvial groundwater. Since spoils groundwater typically has higher TDS concentrations, this could cause an increase in TDS concentration in the alluvial groundwater. Comparison of groundwater levels at alluvial well WA-131 and WS-113 indicates that this might be happening at well WA-131.

- Mining activities are usually associated with some form of dewatering. If mining occurs near the alluvium, these dewatering activities can cause alluvial groundwater to flow towards the active mining and influence the quality of Rosebud Coal or interburden groundwater. This type of alluvial recharge would likely continue until active mining moves further away and water levels in the spoils increase enough to cause the direction of groundwater flow to reverse again. Comparison of groundwater levels at alluvial well WA-125 and interburden and spoils wells WI-157 and WS-157 shows that the alluvium is likely recharging the interburden and spoils at this location.

- The decrease in water levels in the alluvium as a result of dewatering activities in one nearby mine area might cause groundwater from other mining areas to flow towards the alluvium. If that groundwater originates in the spoils, this

might cause TDS concentrations in the alluvium to increase even if groundwater flows from the alluvium towards the closest mining activities. Comparison of groundwater levels in alluvial well WA-128, with those of spoils wells WS-114, WS-106 and WS-118 shows that this might be happening at this location.

Stocker Creek Alluvium

The Stocker Creek alluvium is located in Area C and north of mine Areas A and C. Time series graphs for TDS concentrations are shown on Figure 31. Table 16 gives water quality statistics for the Stocker Creek drainage. The average TDS concentration in the Stocker Creek alluvial groundwater is 2,719 mg/L. TDS concentrations for the alluvial wells in Area C are between 1,500 and 3,500 mg/L (WA-110, WA-111 and WA-217). Groundwater in wells WA-164 through WA-170 has generally higher TDS concentrations between 2,200 and 6,040 mg/L. The earliest mining up-gradient from these wells occurred in 1984, therefore any TDS concentrations measured before that time can be considered baseline values. The TDS concentrations in wells WA-169 and WA-170 seem to be impacted by changes in precipitation, as is illustrated by higher TDS concentrations measured during relatively wetter years.

The time series graphs do not show any long term upward trends in TDS concentrations. Possible exceptions are wells WA-108, WA-109 and WA-167. Given the distance of these wells from the Rosebud coal outcrop to the south, it is highly unlikely that the increase is related to mining activities.

West Fork Armells Creek

The West Fork Armells Creek alluvium is located north of the western portion of Area C. Mining at this location did not start until 2008, so any groundwater samples taken before this date can be considered baseline. Figures 32A and 32B show time series graphs for TDS concentrations in the West Fork Armells Creek drainage and Table 16 summarizes water quality statistics for the drainage. The average TDS concentration in the alluvial groundwater is 3,372 mg/L, which is higher than measured in the Stocker Creek alluvium and the East Fork Armells Creek alluvium within the mine. TDS time series do not show any long term increasing trends for the groundwater in the West Fork Armells Creek alluvium.

Other Major Ions

Comparison of averages of baseline and after mining major ion concentrations shows that the chloride concentration in the Rosebud coal in Area A increased disproportionally compared to TDS. Similarly, comparison of average upstream major ion concentrations for East Fork Armells Creek alluvial groundwater with average major ion concentrations in the alluvium between Areas B and C and between Areas A and B shows that the chloride concentration between Areas A and B increased disproportionally compared to TDS. Chloride time series for all active alluvial monitoring wells between Areas A and B and Rosebud wells in Area A are presented in Figure 33. Note that Area A Rosebud coal well WR-130 is not shown on the figure as it is located in the central part of Area A. Chloride concentrations in this well have remained relatively constant.

The wells showing increases in chloride are located in the vicinity of the facilities area in Area A. The highest chloride concentrations are observed in alluvial wells P-03 through P-05. The chloride concentrations in these wells exceed those in the nearest upgradient spoils well WS-115, in which a maximum chloride concentration of 50 mg/L has been observed. The highest chloride concentration in Area A spoils groundwater is 79.9 mg/L (Table 15A) at WS-114. This indicates that the increase in chloride in this area cannot be explained solely by infiltration from spoils groundwater. A potential source of chloride is magnesium chloride which was used until recently for dust control purposes at Rosebud Mine. A portion of the chloride may have entered the shallow groundwater via runoff from the road bed and possibly from infiltration through the road bed. All wells with elevated chloride concentrations in Figure 33 are located in close proximity to a road. The aerial photograph of this area also shows the presence of several small sediment impoundments or traps next to the main haul roads. Although no recent water quality data are available for these ponds, collection of runoff water from the road followed by evaporation could increase the chloride concentrations in these ponds. The use of magnesium chloride as a dust suppressant has been discontinued at Rosebud Mine. Assuming magnesium chloride is responsible for the disproportionate increases in chloride concentrations, it is expected that elevated chloride concentrations will slowly attenuate with time.

4.2.4.3 Water Quality Standard Exceedances

Table 18 shows exceedances of Circular DEQ-7 (Montana Numeric Water Quality

Standards [October 2012 edition]) Human Health Standards for groundwater. The WECo water quality database contains data for a total of 3,853 groundwater samples, with sampling dates ranging from 1975 to 2011.

The following DEQ-7 (October 2012 edition) water quality standards were evaluated:

Element / Chemical Compound	DEQ-7 Human Health Standard (mg/L)
Arsenic (As)	0.01
Cadmium (Cd)	0.005
Chromium (Cr)	0.1
Copper (Cu)	1.3
Fluoride (F)	4
Lead (Pb)	0.015
Mercury (Hg)	0.002
Nitrate Nitrogen (NO_3-N)	10
Nitrate plus Nitrite Nitrogen (NO_3-N + NO_2-N)	10
Selenium (Se)	0.052
Zinc (Zn)	2

DEQ-7 standards for arsenic, cadmium, fluoride, lead, nitrate plus nitrite and nitrate nitrogen, selenium, and zinc concentrations in groundwater in the Rosebud Mine area have been exceeded. The number of exceedances and the maximum concentration is given in the table below:

Standard	Max Value (mg/L)	Number of Exceedances
Arsenic (As)	0.1	12
Cadmium (Cd)	0.24	63
Fluoride (F)	801	3

Lead (Pb)	0.67	74
Nitrate Nitrogen (NO_3-N)	12	1
Nitrate plus Nitrite Nitrogen	351	24
Selenium (Se)	0.18	3
Zinc (Zn)	8.61	33

There are two wells with more than one sample containing arsenic concentrations higher than the DEQ-7 (October 2012 edition) standard: sub-McKay Coal well WD-195 and interburden well WI-153. The arsenic concentrations in WD-195 range from 0.013 to 0.019 mg/L. Since these samples were taken before mining activities started within 0.5 mile of the well, the concentrations are considered baseline. The arsenic concentrations in well WI-153 range from 0.0089 to 0.018 mg/L and show no persistent trend.

Sixty-eight percent of cadmium exceedances occurred in alluvial groundwater, however cadmium concentrations in excess of DEQ-7 (October 2012 edition) standards were found in groundwater obtained from all geologic strata. Van Voast et al. (1977) reported cadmium concentrations in the groundwater from Colstrip area of 0.01 mg/L or lower. Table 18 shows that 13 samples have cadmium concentrations higher than 0.01 mg/L. No long term trends are observed for any of the wells with more than one sample containing cadmium concentrations in excess of DEQ-7 (October 2012 edition) standards.

The exceptionally high fluoride concentration of 801 mg/L was detected in well WA-118 in 2004. Since the 13 other samples taken from this well contain fluoride concentrations below DEQ-7 (October 2012) standards, it is likely that this high value is due to a laboratory quantification error. The second highest fluoride concentration was 13 mg/L, which was found in groundwater sampled from interburden well WI-102.

The lead exceedances occur in all geologic strata. The Van Voast report from 1977 mentions that higher lead concentrations do occur naturally in the area, but states that the waters associated with the mine spoils might contain higher concentrations and that the lead concentrations could be more diverse in the mined area water. Thebaseline lead concentrations reported by Van Voast et al. range from less than 0.05 to 0.11 mg/L. Lead concentrations in mined areas ranged between less than 0.05 to 0.21 mg/L.

The highest baseline lead concentration in samples collected by WECo is 0.18 mg/L (WI-166). Groundwater samples from McKay coal well WM-158, interburden well WI-162 and alluvial WA-204 contained a lead concentration higher than this baseline value. None of these wells show a persistent trend in lead concentrations.

Nitrate plus nitrite nitrogen exceedances were found mostly in alluvium along the EFAC and spoils wells. The maximum value of 351 mg/L was detected in a sample from alluvial well WA-113. The most recent samples from this well contain nitrate plus nitrite nitrogen concentrations below the DEQ-7 (October 2012 edition) standard. The highest nitrate plus nitrite nitrogen concentration measured in spoils wells is 50 mg/L. High nitrate plus nitrite nitrogen in spoils could possibly be due to dissolved residuals from ammonium-nitrate explosives used in blasting coal and overburden.

Two exceedances of the DEQ-7 (October 2012 edition) standard for selenium were found in alluvial wells and one sub-McKay well. The highest selenium concentration of 0.18 mg/L was measured in a sample taken from alluvial well WA-119. Since the closest mining was occurring at least two miles down-gradient from this well when this sample was taken, it is highly unlikely that this selenium concentration is related to mining activities.

Zinc exceedances were found mostly in coal strata and interburden wells. The highest baseline zinc concentration found in samples collected by WECo is 5.45 mg/L (WD-179). No samples contained zinc concentrations in excess of this baseline value.

4.2.5 Groundwater Use

A comprehensive list of all groundwater users within an area three miles downgradient and one mile upgradient from Areas A, B and C is included in Attachment F. The list was composed using the Montana Groundwater Information Center (GWIC) dataset and the National Resource Information System (NRIS) water rights dataset. Wells owned by WECo and wells mined out before 2013 are not included in the list.

Most of the groundwater users in this list are monitoring wells or wells owned by industrial users (Montana Power Co., Northern Pacific Railway Co., Peabody and Big Sky Coal Co., PPL Montana, B.N.S.F.). The main uses for the remaining groundwater wells are livestock watering and domestic use. Some wells may be removed during mining and will be replaced during reclamation.

4.3 Probable Hydrologic Consequences

Mining impacts of hydrological importance that can occur are destruction of horizontal continuity in the overburden strata and mixture of the overburden strata in the backfilled pits creating a more isotropic media. During this process, some geological materials that are saturated are intermixed with materials that are unsaturated. In addition, a variety of lithologies are mixed including siltstones, sandstones and shales. The mining process substantially increases the surface area of excavated materials exposed to air and water. During the mining process, soil structure is altered, vegetation is removed, and the replaced subsoil and topsoil probably has a slightly increased bulk density.

The dragline removes overburden material by pulling the bucket upward from near the base of the cut toward the top. This material is then "cast" into spoil ridges in the preceding cut. As the stripped overburden material is cast, it is spread over a relatively large area, as much as perhaps 150 meters by 50 meters horizontally and 20 to 30 meters vertically. During this process, the materials are thoroughly mixed, and blocks of geologic materials tumble down steep spoil pile slopes and form a "rubble layer" at the base of the replaced spoil (Van Voast et al., 1988). Moran et al. (1979) conclude that the rubble zone is probably thin but has a substantially higher permeability than the original materials. Backfilled spoils have a higher porosity than the original strata and these spoils probably have a higher vertical percolation rate since the materials when backfilled are more isotropic. Most sedimentary materials exhibit a strong preferential horizontal permeability.

4.3.1 Groundwater Flow

The Rosebud Mine Groundwater Model Report (Attachment D) gives a detailed description of the development of a regional steady-state groundwater model for the Rosebud Mine area. This steady state model was used as the basis for a series of transient groundwater models simulating the mining process from 1975 to current (2012). For a detailed description of the model development, application and results, refer to Attachment D.

The Rosebud Model is used as the starting point to evaluate the groundwater response to the AM4 Amendment mining. This application of the model is designated as the “Area B AM4 Model”. Please refer to the report of this application provided in Attachment E for the discussion of the model development, application and results.

Model simulations predict groundwater drawdowns in the Rosebud and McKay coals at the end of mining and fifty years following the end of mining for both the current permitted mining and the proposed AM4 Amendment. This allows evaluation of the incremental response to the AM4 Amendment. In summary, the AM4 Amendment is predicted to result in an additional 40 feet increase in drawdown at the end of mining when compared to the current permitted mining. At fifty years past, the model simulates a net increase of 15 feet of drawdown in the Rosebud, again when compared to the current permit.

Comparison of the simulated pre-mine and current permitted mine conditions (2012) shows that dewatering of the Rosebud coal will lead to a decline in groundwater levels within Areas A, B and C of the mine and in the immediate vicinity of the mine. Outside of the permit boundary, the projected drawdown is more significant south of Areas B and B extension as compared to other directions. This can be explained by the higher degree of confinement of the Rosebud coal and underlying strata in the southern portions of the mine as compared to the northern mine portion. Another significant factor is that the structural base of the Rosebud coal decreases southward in this portion of the mine. Simulated drawdown for life-of-mine was highest in the Rosebud Coal and neighboring strata.

Mine dewatering discharge rates increase as a result of the proposed AM4 Amendment. Annual and cumulative average mine discharge rates are presented in Table E-1 of Attachment E.

4.3.2 Re-Establishment of Groundwater Levels

A postmine model simulation was run to predict groundwater levels in the Rosebud Mine and its vicinity at 50 years after the cessation of mining (Attachment E). The simulation results show that following mining, water levels should show a gradual recovery. However, substantial residual drawdown is projected to remain fifty years following mining.

Table 19 summarizes water level recovery observed in spoils wells in mine areas A, B, C, D and E to date. A rate of recovery was calculated for each recovering spoils well with a period of record of ten years or more. The average rate of recovery for all Rosebud Mine areas is seven inches/year. The average rate of recovery in Area A is lower at about four inches/year. All of the Area A spoils wells in Table 19 are located in

the southeastern portion of Area A which was mined from 1975 through 1979. The lower recovery rate could be a result of limited lateral inflow from bounding strata. The average rate of recovery in Area B East spoils wells is eleven inches/year. Possible factors influencing this higher rate are lateral inflow from bounding strata and inflow from standing water in mine pits in Area B East. Most Area C spoils wells have been dry to date and only one well had sufficient data to calculate a recovery rate of four inches/year. It is likely that ongoing mining activities in Areas A, B and C are impacting the rate of recovery of spoils groundwater. It is expected that the rate will stabilize after mining activities in the vicinity have been completed. The average recovery rate in Area E, where mining was completed in 1986, is eight inches per year.

As expected, the extension of mining by six years as proposed in the AM4 Amendment delays the groundwater level recovery accordingly. At 50 years past mining, the incremental maximum drawdrown is projected to be about 15 feet greater when compared to current permitted mining.

Outside of the mine permit boundary, at the end of mining (2026), the maximum residual drawdown of 80 feet is predicted to occur in the Rosebud Coal. After 50 years the projected maximum residual drawdown is about 40 feet. Figures showing the drawdowns for these time periods are provided in Attachment E.

4.3.3 Groundwater Quality

The TDS concentration of groundwater in spoils will be higher than the TDS concentration in pre-mine overburden groundwater. At the Rosebud Mine TDS concentrations in spoils groundwater in Areas A, B and C have ranged from 860 to 8,750 mg/L. Average TDS concentrations in Area A, B and C spoils groundwater are 3,103, 3,378 and 5,582 mg/L, respectively. The range of specific conductivity values observed in spoils groundwater categorizes it as Class II or Class III groundwater, which is similar to premine conditions.

In areas where spoils groundwater flows into adjoining strata, it can lead to increased TDS concentrations in those strata. Time series of TDS concentrations in Area A, B and C wells show that this has likely occurred in some areas of the Rosebud Mine. More specifically, inflow of spoils groundwater could be a factor in the increased TDS concentrations that were observed for:

- Selected East Fork Armells Creek alluvial wells between Areas A and B
- Selected Rosebud Coal wells in Areas A and C
- Selected interburden wells in Areas A, B and C

Section 4.2.4.2. - East Fork Armells Creek Alluvium describes some instances where mining activities may have temporarily reversed the direction of alluvial groundwater flow. As a result there are instances where the Rosebud coal, spoils and interburden groundwater between Areas A and B may be influenced by recharge from alluvial groundwater. This type of alluvial recharge is expected to be a temporary result of nearby mining and dewatering activities. As mining moves further away from the alluvium and water levels in the nearby spoils increase, the direction of groundwater is expected to reverse again.

In addition to changes in water quality in the adjoining strata, TDS time series analysis showed that specific geologic conditions, namely thin interburden thickness, may contribute to the vulnerability of the McKay coal and sub-McKay groundwater to changes in water quality. More specifically, possible mining related water quality changes were observed in McKay coal wells in the eastern half of Area B and near the northern permit boundary of Area C and in one sub-McKay well in Area C.

Furthermore, analysis of TDS time series of groundwater in Areas A, B and C shows that the changes in water level associated with nearby dewatering activities likely result in variable TDS concentrations in those wells.

4.3.4 Groundwater Use

The potential hydrological impact from mining in Areas A, B and C on the private wells and water supply wells within a one to three mile radius of the permit boundary is determined by the location of the well with respect to mining and the stratum in which it is completed.

To evaluate potential impacts to private wells, the comprehensive list of groundwater users presented in Attachment F was narrowed down as follows:

- All monitoring wells were removed from the list: MBMG, USGS, Hydrometrics and MBMG wells and wells drilled by Haz Tech Drilling and Maxim Technologies.

- Industrial users were removed from the list: Montana Power Co., Northern Pacific Railway Co., Peabody and Big Sky Coal Co., PPL Montana, B.N.S.F.

- Simulated 5-foot drawdown contours were created for Rosebud coal, McKay coal and sub-McKay at the end of mining in Area B (2026).

Table 20 and Figure 34 present the remaining wells within the maximum extent of the simulated five-foot drawdown contours. The likelihood of these groundwater users being impacted was evaluated based on available static water levels and well log data. This analysis identified four wells that could potentially be impacted by mining:

- GWIC 307: located in Area A, likely mined out
- GWIC 11982: located west of Area B, this overburden well may be impacted by mining, depending on the elevation of the pump in the well.
- GWIC 12002: located in Area B, this well might have been abandoned or mined out

In addition, two wells in Area C will be mined out: WR 42KJ183300 00 and 42KJ 106451 00.

Potential impacts were not evaluated for wells for which no well logs and static water level data are available. In general, the likelihood of impact is dependent on the location of the well with respect to mining and the stratum in which it is completed.

Drawdown maps generated by the Rosebud Groundwater Model show that that wells in the immediate vicinity and to the south of the Area B have the highest potential to be impacted. Alluvial wells to the north and west of Areas A and C and to the west of Area B are not expected to be impacted.

Wells are not likely to be adversely impacted unless the water level in the well is drawn down to the point that the required pumping column for the well cannot be maintained. The required minimum water column is well-specific. Wells that become impacted can be replaced with deeper wells as needed.

5.0 SUMMARY

The general hydrologic consequences as discussed in Section 1.3.1 can be summarized as:

1) Interception of tributary surface flows during mining.
2) Diminished alluvial aquifer recharge from the reduced surface flows during mining.
3) Groundwater level drawdowns resulting from mine dewatering.
4) Changes in groundwater quality as the mined coal is backfilled with spoils.
5) Changes in groundwater quality in the alluvial aquifer associated with spoils.
6) Changes in surface water quality as a result of changes in alluvial groundwater quality.

This comprehensive PHC evaluation compared these hydrologic consequences to the hydrologic monitoring data collected at the Rosebud Mine since 1975. The evaluation generally validates those hydrologic consequences as applicable and identified data limitations and potential future monitoring issues.

Following mining and reclamation, surface water flows and quality should return to pre-mine conditions. Groundwater levels will recover over many years. There is potential for impacts to private wells located near the mine until groundwater levels recover. These impacts can be mitigated. Wells located at distance from the mine should not be impacted. It is anticipated that groundwater quality will reestablish geochemical equilibrium over time. Changes in groundwater quality are not expected to negatively affect existing uses. Future monitoring should focus on spoils water quality and impacts to the alluvial aquifer.

Notes

(a) CG = Crest Gauge, SW = Surface Water

(b) Drainages
EFAC = East Fork Armells Creek
WFAC = West Fork Armells Creek
RC = Rosebud Creek
SC = Stocker Creek (EFAC tributary)
CC = Cow Creek (RC tributary)
PC = Pony Creek (RC tributary)
HC = Hay Coulee (RC tributary)
LC = Lee Coulee (RC tributary)

(c) Status as documented in 2011 Annual Hydrological Report

(d) Only surface water sites in drainages to which Areas A, B and C contribute are shown.

Notes

(a) Values below detection limit were substituted with the detection limit to calculate statistics. No statistics were calculated if 50 % or more than half of the values were below detection limit or if less than 5 samples were available.

(b) Only samples collected upstream from mining and samples collected before mining started upstream from sampling location were considered baseline.

Bicarbonate	mg/L	409	473.5	0.605	852	210	46	0
Carbonate	mg/L			ND	118		45	29
Chloride	mg/L	10	9	0.5	35	7	51	4
Sulfate	mg/L	877	696	5	3220	725	51	0
Nitrate and Nitrite N	mg/L	0.19	0.025	0.005	4.03	0.63	46	24
Fluoride	mg/L	0.34	0.25	0.03	1.4	0.30	51	3
Orthophosphate	mg/L	0.02	0.006	ND	0.188	0.03	51	9

Notes
ND = Value below detection limit.
To calculate statistics, values below detection limit were substituted with half the detection limit.
Carbonate concentrations were below detection limit in the majority of samples, so only minimum and maximum values are given.

Notes

(a) Livestock standards - see Attachment C (lowest of two standards was used).
There were no exceedances of the lifestock standards for akalinity, chloride, cadmium, chromium, copper, fluoride, lead, nitrate+nitrite-N, oil and grease, selenium, vanadium and zinc.
Dissolved constituents concentrations and standards are in mg/L.

Notes
(1) Data collected up to, and including, water year 2011.
(2) Aquifer designation was made based on analysis of outcrop maps, topographical data and information provided by WECo.
(3) This spring could possibly be associated with Rosebud coal
(4) The 2005 aerial photograph shows this spring is located in disturbance area, WECo mapping shows that it is located outside the mined out area. It is designated as a spoils spring, but might be issuing from remaining Rosebud Coal at this location.

ND = Value below detection limit
TDS = Total Dissolved Solids
SC = Specific Conductivity
NC = No statistics were calculated for carbonate concentrations due to high percentage of ND values
Nitrate and nitrate nitrogen statistics were calculated by setting ND values equal to half the detection limit.

Notes

Table contains all Area A, B and C monitoring wells and Area D and E spoils wells.

(a) ***Strata***
OB = Overburden
RCL = Rosebud Clinker
RC = Rosebud Coal
IB = Interburden
SMK = SubMcKay

(b) ***Drainage***
EFAC = East Fork Armells Creek
WFAC = West Fork Armells Creek
SC = Stocker Creek
SpC = Spring Creek
CC = Cow Creek
PC = Pony Creek

(c) **TDS Trend**
Trend designation is based on examination of TDS graphs. All wells for which 2 or more TDS concentrations are available were designated a TDS trend.
Italics - only 2 or 3 data points available

Table 14

		Minimum	1
		Maximum	460
		# Samples	516

Notes
ND - Non-Detect
Source - Area 49 concentrations from Slagle et al. (1983). Groundwater quality data are both from wells > 200 ft deep and < 200 ft deep. No specific aquifer distinction is made in the report.

Notes
ND = value below detection limit.
Baseline samples are samples obtained before mining started within 0.5 miles radius of the well.
(a) Overburden wells 'after mining' are wells located on the periphery of mining activities.
Only two chloride samples were below detection limit. The ND values were not included in the statistics calculation.
Potassium concentrations below detection limit were set to zero to calculate statistics.
All Carbonate concentrations were <= 1 mg/L in all samples.

Notes
ND = value below detection limit
Baseline samples are samples obtained before mining started within 0.5 miles radius of the well.
(a) Overburden wells 'after mining' are wells located on the periphery of mining activities.

Eleven samples out of 475 had chloride concentrations below detection limit. The ND values were not included in the statistics calculation
Potassium concentrations below detection limit were set to zero to calculate statistics.
All Carbonate concentrations were <= 11 mg/L in all samples.

Notes
ND = value below detection limit
Baseline samples are samples obtained before mining started within 0.5 mile radius of the well.
(a) Overburden wells 'after mining' are wells located on the periphery of mining activities.

Potassium concentrations below detection limit were set to zero to calculate statistics.
All Carbonate concentrations were <= 13 mg/L in all samples.

Notes
All carbonate concentrations were <5 mg/L
One sample (EFAC - Downstream) had a chloride concentration below detection limit. This sample was not included in statistics calculation.
Fifty samples had potassium concentrations below detection limit. Statistics were calculated by substituting these concentrations with zero.

Table 17
Montana Groundwater Classification Summary

Classification	Use	Specific Conductance microSiemens/cm @ 25C
Class I	public and private water supplies, culinary and food processing purposes, irrigation drinking water for livestock and wildlife, commercial and industrial purposes	<= 1,000
Class II	public and private water supplies, culinary and food processing purposes, irrigation of some agricultural crops, drinking water for livestock and wildlife, and most commercial and industrial purposes	1,000 to 2,500
Class III	irrigation of some salt tolerant crops, some commercial and industrial purposes, drinking water for some livestock and wildlife, and drinking, culinary, and food processing purposes where the specific conductance is less than 7,000 microSiemens/cm at 25ºC	2,500 to 15,000
Class IV	some industrial and commercial uses	> 15,000

Notes

(a) Samples from wells in Area A, B and C and spoils wells in Area D and E.
Circular DEQ-7, Montana Numeric Water Quality Standards, October 2012 edition.

(b) ***Drainages***
EFAC = East Fork Armells Creek
WFAC = West Fork Armells Creek
RC = Rosebud Creek
SC = Stocker Creek (EFAC tributary)
SpC = Spring Creek (RC tributary)
CC = Cow Creek (RC tributary)
PC = Pony Creek (RC tributary)
CoC = Corral Creek (EFAC tributary)

(c) Baseline samples are samples obtained before mining started within 0.5 mile radius of the well.

Notes

Other factors may contribute to the rate of recovery in these wells as there are ongoing mining activities in Areas A, B and C.
Wells exhibiting recovery and for which more than 10 years of water level data are available are shown.

Notes

(a) Non-industrial groundwater users within 2026 five foot drawdown contour (incl. Rosebud coal, McKay coal and subMcKay).

(b) Types
D = Domestic
I/C = Industrial or Commercial
M = Municipal
P/O = Private or Other
S = Stock

(c) Two public datasets from the National Resource Information System (NRIS) were consulted: GWIC wells and Water Rights Data
Mined out wells were removed from the selection. When enough data was available (well depth and completion/priority date) duplicate entries were merged.

(d) Potential impact: Y = yes, N = no, U = unknown, not enough information availabel to draw conclusion

Exhibit 8

06295000 Yellowstone River at Forsyth, Mont.
Site Number 182

LOCATION.--Lat 46°15'58", long 106°41'24" (NAD 27), in NE¼NW¼NW¼ sec.23, T.6 N., R.40 E., Rosebud County, Hydrologic Unit 10100001, on right bank 0.3 mi downstream from U.S. Highway 12 bridge, at Forsyth, and at river mile 238.2.

DRAINAGE AREA.--40,146 mi^2.

PERIOD OF RECORD.--July 16, 1921, to September 30, 1923 (no winter records), October 1977 to current year (2002). Miscellaneous discharge measurements were made in 1974 to 1976 and are available in files of U.S. Geological Survey Montana District Office.

GAGE.--Water-stage recorder. Altitude of gage is 2,504.62 ft (NGVD 29), from nearby elevation determined by City of Forsyth. July 1921 to March 1922, nonrecording gage on discontinued highway bridge 10 ft downstream from gage at different datum. March 1922 to September 1923, nonrecording gage on discontinued highway bridge 10 ft downstream from gage at datum 2 ft higher.

REMARKS.--Diversions for irrigation of about 838,000 acres upstream from station. Flow regulated to some extent by Bighorn Lake, usable capacity, 1,312,000 acre-ft, on Bighorn River. Small diversion dam about 4,200 ft downstream from station. Bureau of Reclamation satellite telemeter at station.

Magnitude and probability of annual low flow

Exhibit 8

06296003 Rosebud Creek at mouth, near Rosebud, Mont.
Site Number 185

LOCATION.--Lat 46°15'53", long 106°28'30" (NAD 27), in SW¼NW¼NE¼ sec.21, T.6 N., R.42 E., Rosebud County, Hydrologic Unit 10100003, on left bank 0.4 mi upstream from bridge on Interstate Highway 94, 0.8 mi upstream from mouth, and 1.6 mi southwest of Rosebud.
DRAINAGE AREA.--1,302 mi^2.
PERIOD OF RECORD.--October 1974 to current year (2002).
GAGE.--Water-stage recorder. Altitude of gage is 2,480 ft (NGVD 29).
REMARKS.--Diversions for irrigation of about 2,000 acres upstream from station.

Magnitude and probability of annual low flow based on 27 years of record

Rosebud Mine Groundwater Model
Western Energy Company

1.0 INTRODUCTION

1.1 Background

Western Energy Company - Rosebud Mine (WECo) has requested that Nicklin Earth & Water, Inc. (NE&W) conduct a hydrologic/hydrogeologic evaluation and then perform a groundwater modeling effort focusing on projected responses to mining associated with existing permits. Note that the Rosebud Mine Groundwater Model (GM) encompasses mining efforts specifically to permitted mining for Areas A, B, and C. Data from other areas are included in the baseline model, including data from Area E, additional monitoring sites outside the permit areas, and data collected at the Big Sky Mine.

1.2 Groundwater Modeling Objectives

The following are the modeling objectives:

- Objective 1: To summarize the conceptual understanding of the hydrogeologic regime at the Rosebud Mine for purposes of constructing a groundwater model focusing on existing permits.

- Objective 2: To develop a calibrated model with reliable predictive capability.

- Objective 3: To predict temporal and long-term hydraulic/hydrologic responses associated with existing and proposed permits.

Objective 1 is achieved through the baseline studies of the mine area hydrology, and the existing Probable Hydrologic Consequences (PHC) assessment. A combination of

these efforts provides substantial information for formation of a numeric simulation model which can be used to emulate the existing system responses to date, and then used to predict future system responses to mining activity. The last two objectives are achieved via the modeling effort described herein.

1.3 Modeling Approach

The groundwater modeling (modeling) effort includes the following:

- Element 1 - Development of the conceptual groundwater model.
- Element 2 - Definition of model structure and model calibration.
- Element 3 - Utilization of the calibrated model to evaluate hydraulic responses related to mining at the Rosebud Mine.

The following activities were performed:

- Developed model structure including model domain extent, steady-state model boundary conditions, and steady-state model stresses.
- Conducted steady-state model calibration.
- Completed steady-state sensitivity analysis.
- Ran transient simulations through the period of record to test the reliability of the steady-state calibration effort. A focus was placed on evaluating storativity.
- Conducted the following applications:
  - Simulated groundwater level changes over time.
  - Simulated water budget changes associated with mining.

1.4 Overview of Conceptual Model

1.4.1 Project Location

A map of the Rosebud Mine and the surrounding area is given in Figure GM-1**.**

1.4.2 Climate

The climate of eastern Montana is classified as semiarid continental and is characterized by hot moderately dry summers, cool dry falls, cold dry winters and cool moist springs typical of southeastern Montana. Winter cold spells are often interrupted by periods of warmer weather. The passage of mid-latitude storm systems is typical of the climate of this area; day-to-day weather changes can be extreme because of the migrating systems.

At the mine, precipitation occurs predominantly as snow from about November to April. About one-third of the total annual precipitation is in the form of snow. Due to the prevailing westerly wind, the snow typically accumulates on the leeward slopes of drainages. The average annual precipitation at Colstrip is 15.17 inches.

The average maximum and average minimum daily temperatures as measured at Colstrip are 88.1^{o} F in July and 9.6^{o} F in January respectively. The maximum and minimum temperatures ever recorded at Colstrip are 111° F (August 6, 1961) and -50° F (February 15, 1936).

1.4.3 Geology

General Stratigraphy

The Rosebud Mine lies entirely within the outcrop of the Fort Union Formation (Paleocene Age). Consolidated sedimentary rocks ranging in age from Cambrian to Cretaceous underlie the Fort Union Formation.

The Fort Union Formation is subdivided into three primary members that are designated as follows (see Figure GM-2):

- Tongue River Member;
- Lebo Member (or Lebo Shale); and

- Tullock Member.

The primary coal-bearing formation of the Fort Union is the Tongue River Member. Figure GM-3 provides a geologic outcrop map of the region surrounding the Rosebud Mine.

Tongue River Member

The Tongue River Member is the upper-most consolidated rock unit found in the immediate vicinity of the Rosebud Mine. The Tongue River Member can be as thick as 540 feet. This member outcrops throughout the Colstrip vicinity, except, where covered by alluvium or colluvium.

The Tongue River Member consists of fine-grained sandstone with thinner inter-beds of yellowish brown, orange, or tan siltstone; light-colored to dark-colored mudstone and clay; and coal beds. The sandstone tends to be massive or cross-bedded. Given that the Tongue River Member was deposited in a fluvial environment, it typically exhibits rapid vertical and lateral transitions in lithology. Although sandstone units occur, they are rarely laterally continuous, but more likely exist as isolated lenses. The coal beds tend to be much more laterally continuous than other lithologic units found in the Tongue River Member. In some instances, these coals burned near outcrops or in areas where the coal was present at relatively shallow depths. Any immediately overlying sandstones, mudstones, shale, and/or claystone were baked forming clinker. Note that local residents often apply the name “scoria” to this clinker. The clinker tends to be very resistant to erosion and it often leads to ridges forming where it is present.

Immediately underlying most of these coal beds is “under-clay” which is referred to in some portions of the country as “fire clay.” This under-clay tends to possess extremely low permeability. There are multiple coal beds in the Tongue River Member ranging from less than one foot to relatively greater thicknesses, such as the Rosebud coal. Given that these under-clays typically appear in concert with the coal seams, they are

also relatively more laterally extensive than other lithologic units present in the Tongue River Member. These under-clays and mudstones have significant implications as they substantially impede the vertical flow of groundwater. This impedance leads to the substantial vertical hydraulic gradients, and the significant potentiometric head separation, observed moving downward through the Tongue River stratigraphic sequence.

The specific consolidated hydrogeologic units within the Tongue River Member considered in the modeling effort are condensed to the following:

- Overburden (consists of multiple stratigraphic units and may contain clinker associated with shallower burned coal beds);
- Rosebud coal (often directly in contact with clinker);
- Interburden (Tongue River between Rosebud coal and McKay coal; and consists of multiple stratigraphic units);
- McKay coal
- Sub-McKay (Tongue River below McKay coal and consists of multiple stratigraphic units), which is in some instances referred to as sub-McKay sands.

In some portions of the coal beds, partings are present so that even individual coal beds could be considered multi-layered.

Lebo Member

The Lebo Member (Lebo shale) is the middle unit of the Fort Union sequence. This member is dominated by gray, smectitic shale and mudstone containing lenses of gray and yellow, very fine- to medium-grained sandstone, ironstone concretion zones from 1 to 12 inches thick, and a few thin coal beds (Vuke, et al, 2001). The thickness of the Lebo shale ranges from 95 to 200 feet in the region of the Rosebud mine. The Lebo shale is a confining unit in the area of the Rosebud Mine. It acts to retard groundwater flow much more significantly than does either the Tongue River or the Tullock members

of the Fort Union. The Lebo shale does not produce water except in relatively rare circumstances where localized sandstones exist. This Lebo shale outcrops/sub-crops north, east and west of the Rosebud Mine as seen in Figure GM-3.

Tullock Member

The Tullock Member of the Fort Union is the lowermost unit and is a light-yellow to light-brown, planar-bedded, fine-grained to medium-grained sandstone containing minor amounts of gray shale. Its thickness is about 240 to 260 feet. Sandstones of this member commonly provide water to wells at sufficient rates for domestic use and stock watering purposes.

Alluvium

The unconsolidated geologic deposits of main hydrologic interest in the immediate vicinity of the Rosebud Mine are of Quaternary age and consist of alluvium and colluvium. The main water-bearing unit when it is saturated is alluvium. Alluvium can vary widely in thickness, being generally less than 15 feet but it can be up to 35 feet in some areas (Vuke, et al, 2001).

1.4.4 Hydrogeologic/Hydraulic Properties

The water-bearing properties of the overburden, Rosebud coal, interburden, McKay coal, sub-McKay (underburden) and alluvium are discussed below.

Overburden

Again, the overburden above the Rosebud coal is comprised of interbedded sandstone, siltstone, mudstone, claystone, clinker, and coals. It appears in reviewing exploration logs, and then comparing those logs to observation well logs, that an alternative designation by some is to identify this mudstone as shale. Upper relatively shallower and elevated portions of the overburden above the Rosebud coal are more likely to be

unsaturated, except, in instances where perched groundwater is present. The perching is typically due to presence of mudstone (often coal under-clays) and claystone. In effect, the mudstone and claystone act to significantly retard the rate of flow through this overburden (and through the interburden and Sub-McKay as well) leading to perching of groundwater. Personal communications with Mr. Glenn Miller, geologist with Pronghorn Geologic Services (2013) indicate that the dark grey mudstones possess “extremely low permeability.” Similarly, Mr. Charlie Speake, mining engineer with WECo describes the prevalence of under-clays beneath the mine coal seams.

Again, the presence of mudstones intermixed with more permeable strata (e.g., sandstone or coal) leads to perching conditions, or otherwise, substantial impedance of vertical flow in the Tongue River strata. The significance of this issue is illustrated in Figure GM-4 and Figure GM-5. Figure GM-4 provides a conceptual cross-section of vertical flow. Figure GM-5 provides a sample calculation using principles of hydraulic conductivity as it is affected by anisotropy in multi-layered systems. Note that the effective vertical hydraulic conductivity is dominated by the magnitude of the conductivity of the low permeability units, in this instance, mudstone. Yet, the effective horizontal conductivity is dominated by the magnitude of the conductivity of the high permeability unit, in this case, the sandstones. The net effect of the multilayered systems of the Tongue River is to yield very large horizontal to vertical conductivity ratios or very low leakances. The hydraulic properties of the overburden vary widely as seen in Figure GM-6.

Clinker

Clinker deposits are red, pink, orange, black, and yellow, very resistant, thermally metamorphosed sandstone, siltstone, and shale of the Fort Union Formation. This clinker formed due to burning of the underlying coal followed by the collapse into the burned coal void space. Thicknesses of clinker range from as little as 10 feet up to 300 feet (Vuke, et al 2001). From a hydrogeologic perspective, these deposits are extremely permeable. They typically possess hydraulic conductivities several orders of

magnitude higher than other strata of the Tongue River member. Generally, the saturated thickness of clinker at the Rosebud Mine ranges from dry to a few feet in those instances when water is perched. Clinker is important from a recharge perspective. This clinker tends to be near the surface. Hence, given its very high permeability, greater recharge rates occur as well. Although this water tends to perch on low-permeability strata beneath the former coal, this perched water acts as a long-term source of seepage passing through any formation weakness, such as fractures and/or joints that are present.

An example of the relevance of clinker deposits as a recharge source occasionally occurs at the Stocker Creek flow measurement station SW-65. Stocker Creek is an ephemeral drainage, or a creek that is typically dry during normal years. Measurement station SW-65 is close to the headwaters of Stocker Creek. After a major precipitation or snowmelt event, flow may begin and then continue at this station for extended periods. For instance, a rare 10-inch precipitation event occurred in May 2011. After that event, flow was present at SW-65 until that flow ceased in early June 2012. It remained dry thereafter until late February of 2013. The best explanation for this sustained flow after the major recharge events is the presence of a substantial amount of clinker bounding Stocker Creek. Significant recharge occurred from the May 2011 event and was temporally stored in the clinker. Seepage from the clinker then sustained flow in Stocker Creek for an extended period. Hence, given that clinker is relatively abundant around the Rosebud mine, its presence is a significant source of recharge in the mine vicinity.

Some portions of eroded clinker also serve as gravel in the alluvial deposits, leading to a very permeable substrate. The alluvial clinker tends to concentrated in lower portions of the alluvium, which acts as the primary conduit for aquifer flow in the alluvial drainages.

Rosebud Coal/Interburden/McKay Coal

The Rosebud coal is the target of mining operations. This coal is typically about 26 feet thick at the Rosebud Mine. The water yielding capacity of this coal is limited, owing to the relatively low transmissivities in that coal. Transmissivity information for the Rosebud coal is provided in Figure GM-6. If this coal is sufficiently confined, it can supply water to provide limited sources of well water for both domestic and stock water users in the region. Nearer the coal outcrops, this coal is unconfined. In more southerly and up-gradient portions of the Rosebud Mine, and away from active coal mining, the Rosebud coal is semi-confined. In a few instances, where this coal outcrops, low flow springs or seeps occur (e.g., SP-35, SP-26, Spring 7). For spring locations refer to Figure GM-7.

The interburden is a convenient term used to define the stratigraphic sequence of the Tongue River Member between the Rosebud coal and the McKay coal. Its properties are similar to that of the overburden, i.e., it is a multilayered sequence. The thickness of the interburden varies substantially ranging from a few feet in some instances to well over one-hundred feet in other instances. The interburden typically possesses very low hydraulic conductivities and transmissivities (Figure GM-6).

The McKay coal underlies the interburden. In some portions of the region, this coal nearly merges with the Rosebud coal (as the interburden thins). The McKay coal is not a mining target for the Rosebud Mine. From a hydrogeologic perspective, it does not possess sufficient transmissivity to provide a reliable source of groundwater to wells. On the other hand, there is sufficient groundwater to yield low-flow springs and seeps in some instances at the outcrop/subcrop of this coal (e.g., SP-27, SP-63 and Spring 2). Figure GM-6 provides representative values of transmissivity for the McKay coal.

Alluvium

The most transmissive water-bearing alluvial deposits are present in the main drainages transecting the Rosebud Mine area, or in lower portions of the East Fork Armells Creek (E. Armells Creek) drainage (refer to Figure GM-1). The most transmissive alluvial aquifer sequence adjacent to the Rosebud Mine is likely the main stem of E. Armells Creek between Areas A and C to the North, and Areas B and B-extension to the south. The saturated thicknesses are up to as much as approximately 30 feet in this portion of E. Armells Creek (e.g., well P-05). Figure GM-6 provides a summary of the range of hydraulic properties for alluvium found at the Rosebud Mine.

Other Factors (Faults)

A potential factor affecting groundwater flow in the Rosebud Mine vicinity is the presence of faults. Several faults have been identified in the area by the MBMG and the USGS. In addition, an evaluation of exploratory logs indicates that another fault may be present at the western edge of the model domain (near Robbie Creek). Figure GM-8 identifies the existing faults and potential fault alignments.

The faults may act in different manners as they affect the local flow of groundwater. One way they may affect flow is if they truncate a given water-bearing stratum, effectively creating a local boundary to impede groundwater flow. These faults may also be associated with increased fracturing which could increase local transmissivity, flow, and/or local recharge to underlying strata. Based upon communications with mine staff, they have not observed a tendency for the Rosebud coal to be offset to the degree that the coal is truncated. Rather, the Rosebud coal beds tend to “bend” locally so that they remain connected, at least in areas that have been mined. However, given that the McKay is thinner, it is possible for this coal to be offset to the degree that it is truncated leading to a “no-flow” or “low-flow” boundary.

1.4.5 Observation Well Network and Well Hydrograph Summary

The monitoring well network for the vicinity of Rosebud Mine is subdivided into the primary formations of interest, for purposes of evaluation:

- Overburden
- Rosebud coal
- Interburden
- McKay coal
- Sub-Mckay (underburden)
- Alluvium
- Spoils

Well water level data that have been collected to date by WECo were compiled and evaluated by NE&W. Wells with sufficient data to develop hydrographs were plotted in Figures GM-9 through GM-17. All the well hydrographs are plotted at the same relative scale, except where noted, so that differences in variability can be compared. The relatively large scale for the ordinate shown on these figures makes it possible to account for the range of water level changes observed, and to provide the same relative perspective for comparing well responses to mining.

A summary of hydrograph observations is presented below.

Overburden Well Summary

Refer to Figure GM-9 (page 1), Figure GM-11 (page 1), Figure GM-12 (page 1), Figure GM-13, Figure GM-14 and Figure GM-17 (page 1) for overburden well hydrographs.

A majority of the overburden wells have been non-responsive to mining activities demonstrating that most of the overburden strata are hydraulically isolated from the underlying Rosebud coal. This observation is consistent with the conceptual model described previously. The presence of low permeability strata such as mudstones and claystones, and, under-clay associated with shallower coal seams, impedes flow downward to the Rosebud coal.

Examples of wells showing some response to nearby mining include:

- WO-101 and WO-173 (Area B-extension - Figure GM-11, page 1) – observed water level decline of about 6 to 9 feet [note that some caution is warranted here as an extended drought also could explain portions of any declines that are observed].
- WO-103 (Area C east - Figure GM-12, page 1) - observed decline of about 8 to 9 feet.
- WO-154 (Area C east - Figure GM-12, page 1) - observed decline of about 16 to 17 feet.
- WO-165 (Area C east - Figure GM-12, page 1) - observed decline of about 14 feet.

Again, some caution is warranted here in concluding that the changes in water level described above are entirely mining related. An extended drought may have been a factor for explaining portions of groundwater level declines in the overburden. With respect to declines in the overburden, it is probable that portions of the decline are directly caused by overburden removal during the mining process, and not by dewatering of the Rosebud coal. In other words, there is some question as to the degree of direct hydraulic communication between the overburden and the Rosebud coal. This is because some overburden wells may be measuring perched groundwater, rather than water connected directly/hydraulically to the Rosebud coal.

In summary, overburden wells have generally not been that responsive to mining activity with a few exceptions involving wells that are located very near active high walls. In essence, the observation data demonstrate that the radius of influence of mining activities on the overburden water levels is very limited.

Rosebud Coal Observation Well Summary

Refer to Figure GM-9 (page 1), Figure GM-10 (page 1), Figure GM-11 (page 2), Figure GM-12 (page 2), Figure GM-13, Figure GM-14 and Figure GM-17 (page 2) for a summary of Rosebud coal well hydrographs.

The response of Rosebud coal wells to mining has been variable. Some wells responded to nearby mining whereas other wells have not. Examples of wells showing response to mine dewatering include:

- WR-101 (Area B - Figure GM-10, page 1) - observed drawdown of about 58 feet.
- WR-161 (Area B - Figure GM-10, page 1) - observed drawdown of about 62 feet.
- WR-162 (Area B extension Figure GM-11, page 2) - observed drawdown of about 13 feet.
- WR-117 (Area C east - Figure GM-12, page 2) - observed drawdown of about 27 feet.

The radius of influence of mining on Rosebud coal water levels appears to be limited mainly to areas relatively near the mine pit high walls, especially during active mining.

Interburden Observation Well Summary

Interburden well hydrographs are provided on Figure GM-9 (page 2), Figure GM-10 (page 2), Figure GM-11 (page 3), Figure GM-12 (page 3), Figure GM-13 and Figure GM-14.

The response of interburden wells to mining has been variable. Some wells have responded to nearby mining whereas other wells have not. Examples of wells deemed responsive to mine dewatering include:

- WI-103 (Area B - Figure GM-10, page 2) - observed decline of about 73 feet.
- WI-157 (Area B - Figure GM-10, page 2) - observed increase in water level of about 39 feet. Well is near E. Armells Creek alluvium.
- WI-164 (Area B extension - Figure GM-11, page 3) - observed decline of about 21 feet.

In summary, a majority of interburden wells have not responded to mining activity with a few exceptions involving wells located very near the active high walls. In some instances, water levels in interburden wells have increased (e.g., WI-157). One potential factor responsible for these increases may be regional joints and faults that transect the area. Another likely factor affecting some wells is their relative proximity to E. Armells Creek alluvium.

The radius of influence of mining activity on interburden water levels is considered limited.

McKay Coal Observation Well Summary

McKay coal well hydrographs are provided Figure GM-9 (page 2), Figure GM-10 (page 3), Figure GM-11 (page 4), Figure GM-12 (page 4), Figure GM-13 and Figure GM-14 and Figure GM-17 (page 3).

The response of McKay coal wells to mining has been variable. Most wells have not responded to nearby mining. Examples of wells responding to mining include the following:

- WM-104 (Area A - Figure GM-9, page 2) - observed decline of about 20 feet.
- WM-157 (Area B - Figure GM-10, page 3) - water level increase of about 29 feet.
- WM-161 (Area B - Figure GM-10, page 3) - observed decline of about 57 feet.
- WM-164 (Area B extension - Figure GM-11, page 4) – observed decline of about 20 feet.

In summary, a majority of McKay coal wells have not responded to mining activity with the few exceptions being wells located very near the active high walls. In some instances, water levels in McKay coal wells have increased (e.g., WM-157). One potential factor responsible for these increases may be regional joints and faults that transect the area. Another factor may be the relative proximity of wells to the E. Armells Creek alluvium.

Underburden (Sub-McKay) Observation Well Summary

Sub-McKay well hydrographs are provided on Figure GM-10 (page 4), Figure GM-11 (page 5), Figure GM-12 (page 5) and Figure GM-17 (page 4).

The majority of sub-McKay wells have not responded to nearby mining activity. One possible exception is WD-100 in Area B (Figure GM-10, page 4), in which a decline in water levels of about 45 feet was observed.

Alluvial Observation Well Summary

Representative hydrographs from alluvial wells located between Areas A and B, and between Areas B and C are presented in Figure GM-15.

A review of the well hydrographs indicates that climatic factors dominate alluvial well water levels at/near the Rosebud Mine. However, some alluvial wells in the immediate vicinity of E. Fork Armells Creek appear to have shown effects of dewatering when mining/dewatering was performed in nearby areas (e.g., WA-211, WA-212, WA-213, WA-209) [refer to page 2 of Figure GM-15]. Other alluvial wells have not responded. Again, some observed responses are due to non-mining factors such as drought conditions. In some instances it is difficult to ascertain the primary factor (mining or climate-related) responsible for the changes that are observed (e.g., WA-127, WA-131).

In general, with the exception of the temporal dewatering observed when mining occurred adjacent to the E. Fork Armells Creek alluvium, most of the alluvial well responses in the Rosebud Mine area (both decreases and increases) correlate to climate as opposed to being mining induced.

2.0 MODEL DEVELOPMENT

2.1 Model Code Selection

The modeling effort was conducted using the program entitled MODFLOW: “A modular three-dimensional finite difference groundwater flow model developed by the United States Geological Survey” (McDonald and Harbaugh, 1988). MODFLOW 88/96 was used for model simulation efforts.

The three-dimensional movement of groundwater of constant density through porous earth material may be described using the following partial differential equation:

$$\frac{\partial}{\partial x}\left(K_{xx}\frac{\partial h}{\partial x}\right)+\frac{\partial}{\partial y}\left(K_{yy}\frac{\partial h}{\partial y}\right)+\frac{\partial}{\partial z}\left(K_{zz}\frac{\partial h}{\partial z}\right)-W=S_s\frac{\partial h}{\partial t}$$

K_{xx}, K_{yy} and K_{zz} are values of hydraulic conductivity along the x, y, and z coordinate axes; h is the potentiometric head; W is volumetric flux; S_s is the specific storage; and t is time.

2.1.1 Rationale for Using MODFLOW

MODFLOW is a three-dimensional finite difference numerical simulation tool used to solve the above equation for a variety of complex conditions. MODFLOW, which is a public domain code, is the most widely used groundwater flow code. The code has been validated and most groundwater hydrologists/hydrogeologists are familiar with MODFLOW.

2.1.2 MODFLOW Packages

MODFLOW consists of a main program that applies a series of highly independent subroutines called “modules.” These modules are grouped into packages. The

packages may be combined to simulate a variety of groundwater flow conditions. In a sense, the manner that these packages may be pieced together is akin to “à la carte” dependent upon the situation. Some of these packages are required while others may be used for site-specific circumstances.

The following are packages which have been developed for MODFLOW. Parentheses () indicate if a package is required or discretionary. Brackets [ ] identify packages which were employed in the Rosebud Mine model.

- Basic Package (required) ***[BAS1 used]***.
- Block Centered Flow Package ***[BCF used]***
- Solver Package (one of these is required):
    - Strongly Implicit Procedure (SIP1)
    - Pre-Conditioned Conjugate Gradient (PCG1, PCG2, PCG3) ***[PCG2 used]***
    - Slice Successive Overrelaxation (SOR1)
- Recharge Package (discretionary) ***[RCH used]***
- Evapotranspiration (discretionary)
- Drain Package (discretionary) ***[DRN used]***
- River Package (discretionary)
- General Head Boundary Package (discretionary)
- Well Package (discretionary) ***[WEL used]***
- Horizontal Flow Barrier (discretionary)
- Stream Package (discretionary)
- Time Variant Specified Head (discretionary).

The packages that were employed in the Rosebud Mine model are briefly reviewed below.

Basic Package

The basic package serves as the administrator for MODFLOW. It has the following purposes:

- Identifies all the other packages which are to be incorporated into the model;
- Defines the active portions and grid characteristics of the model (that portion of the model domain which is included in the simulation process);
- Establishes initial conditions (e.g., starting heads);
- Defines stress periods and stress period lengths (e.g., the length of time, and the manner the time in each model run is subdivided);
- Computes the volumetric budget for entire model (e.g., summarizes all the inflows, outflows and changes in water storage in the model domain); and
- Defines the output control (portions of the modeling information that will be printed to output files).

Block Centered Flow Package

The Block Centered Flow Package is used to perform the following tasks:

- Defines whether the simulation is to be steady-state or transient;
- Develops the row and column sizes;
- Describes the layer type (confined or unconfined);
- Defines the storage properties;
- Defines model layer parameters;
- Transforms the input parameters to coefficients for the numerical matrices; and
- Determines the rate that flow moves into and out of storage at each model cell.

Solver Package

There are several numerical tools for solving the model's mathematical structure once it has been created to represent the groundwater flow system. As stated before, there are

three classes of solvers commonly employed with MODFLOW. The choice of the appropriate solver varies from application to application as one solver may work well for one problem, but not work so well on another. The PCG2 solver worked the best for this model simulation effort.

Recharge Package

The Recharge Package (RCH) is designed to simulate areal recharge over a model domain. For the Rosebud Mine area, this package was used to represent the net recharge less any direct abstractions such as evaporation and evapotranspiration. All water added over areal portions of the model domain is via the recharge package.

Drain Package

The purpose of the Drain Package is to simulate the effect that certain types of sinks, such as agricultural drains, have on groundwater systems. An inherent assumption in using the drain package is that drains can only remove water from a groundwater system. In essence, the groundwater potentiometric head must be above the base of the drain for it to remove water. When simulated heads are below the drain, no flow exits from a model cell used to emulate a drain.

The rate that flow passes from a drain is also directly proportional to the conductance of the drain. In essence, the Drain Package applies a numerical form of Darcy's Law in accounting for the rate that water leaves the subsurface via a drain.

The Drain Package was used to represent some of the larger channel, coulee, gully and/or ephemeral stream features in the mine vicinity.

The Drain Package was used as well to represent the hydraulic sinks associated with the mining process during the transient modeling phases.

Well Package

In one instance, the well package was used to represent a stock well. Refer to Section 2.1.4 for more details.

Graphical User Interfaces/Automatic Parameterization

Graphical User Interfaces (GUIs) were applied extensively in the Rosebud Mine modeling effort. The GUIs were used to:

- Compile all relevant hydrologic/hydrogeologic information into a relational database and into a visual format.
- Assist in creation of initial model structure and input files;
- Revise the model structure as necessary during the course of the modeling effort;
- Create and modify parametric zones;
- Modify parameters within zones during calibration;
- Provide calibration statistics during model calibration; and
- Develop presentation graphics for exhibiting simulation results.

ARCVIEW was used to develop model background images. In addition, drawing files from WECo were used to define mine progression over time.

Groundwater Vistas (GV), developed by Environmental Simulations, Inc. of Herndon, Virginia, served as the numerical interface for conducting groundwater simulations via MODFLOW. The GV interface served as both a pre-processor and post-processor for purposes developing the model input files, evaluating the simulation results, and for conducting sensitivity analysis.

For additional details about GV, the documentation associated with GV should be consulted.

In addition to using both ARCGIS and GV, Golden Software Surfer was used for developing illustrations from simulation results exported from GV. This included development of the potentiometric surfaces and drawdown for both steady-state and transient simulation efforts.

2.1.3 Model Construction/Calibration/Application Approach

The primary steps used to construct the groundwater model were the following:

- Step 1: The ARCVIEW database was constructed using a combination of the data available in Montana's Natural Resource Inventory System (NRIS) [coordinates were in NAD-83 State-Plane, feet].
- Step 2: Relevant graphical files were exported from ARCVIEW and then imported into Groundwater Vistas to assist in defining the following components of the model structure with the following general attributes:
    - Model domain was defined. The approximate model dimensions are about 27 miles (N-S) by 36 miles (E-W).
    - A variable spaced grid was used. However, a uniform grid density was applied to areas of permitted mining.
    - Five model layers were defined.
- Step 3: Initial model transmissivity and hydraulic conductivity values were assigned values similar in magnitude to those quantified in the Environmental Impact Statement (State of Montana, 1982) [refer to Figure GM-7].
- Step 4: Recharge values were initially distributed uniformly assigning a value of 0.25 inches per year.
- Step 5: The following model parameters were defined and modified area-wise as necessary to achieve as reasonable an approximation to potentiometric head as feasible:

  - Transmissivity
  - Recharge
  - Leakance (represents relative ease with which water may flow vertically).
- Step 6: A steady-state model calibration effort was first completed using the calibration targets presented in Table GM-1. The focus of target selection was to use water level data collected before the impacts of mine disturbance were significant. In some instances, mining had occurred prior to the collection of groundwater level data. Emphasis was placed on using data from wells deemed as representative of actual conditions. More information on the target selection process is given in Attachment GM-A. In areas of multiple well clusters of the same aquifer unit, one representative well was defined to reduce calibration bias. The steady-state calibration effort included modifying transmissivity, recharge, and leakance using a combination of the following:
  - Trial and error variation of parameters;
  - Use of the auto-sensitivity run feature of GV which allowed multiple simulations to be run automatically; and
  - PEST (Model-Independent Parameter Estimation, Doherty (2005)).
- Step 7: A series of sequential transient models representing each year of the mining process starting 1975 and ending in 2011 were constructed for conducting the simulations used to represent the extraction of groundwater during mining.
- Step 8: Sensitivity analysis was conducted focusing on storativity for the various hydrogeologic units to determine reasonable values of this parameter.
- Step 9: Transient model simulations were conducted for permitted mining extending to 2020 for Areas A, B, and C.

For Step 9, it is likely that actual mining timing set forth for future dates will vary from the projected dates depending upon coal demand, etc.

2.1.4 Summary of Model Construction

The areal domain of the groundwater model relative to the Rosebud Mine is shown in Figure GM-18. The domain varies by layer.

Vertical Discretization

The hydrogeology was represented in the model using a five-layer model. All layers were assumed to possess constant saturated thickness (confined). A limiting factor in selecting the most applicable criterion (confined versus unconfined) is the fact that some areas of the aquifer system in the vicinity of simulated area may be confined and others may be unconfined. Furthermore, even individual stratigraphic units can vary geographically from confined in one instance to unconfined in other cases (e.g., nearer outcrops).

The model layers were assigned as follows below (pre-mine conditions):

- Layer 1: Overburden and alluvium.
- Layer 2: Rosebud coal and alluvium
- Layer 3: Interburden and alluvium
- Layer 4: McKay coal
- Layer 5: Shallow Underburden or sub-McKay (confined)

The model layer thicknesses assigned to compute this transmissivity were as follows:

- Layer 1: 30 feet
- Layer 2: 26 feet
- Layer 3: 50 feet
- Layer 4: 8 feet
- Layer 5: 50 feet

Note that since the model is transmissivity based the thickness is not directly used in the simulation model of MODFLOW. The main purpose of assigning thicknesses was to calculate transmissivity. However, in the case of the Rosebud coal and McKay coal, the model layer thicknesses of 26 feet and 8 feet are deemed to be representative of the approximate thickness of these coals.
There are certain advantages and limitations in assuming that each of the modeled water bearing units is confined when compared to the potential for unconfined conditions when using MODFLOW. These include the following:

Advantages:

- The model construction process is greatly simplified. For instance, the elevation of specific stratigraphic features, or the elevation of specific model layer components, must be known throughout the model domain in order to define the structure of the unconfined model. This is generally an impractical requirement except in the immediate vicinity of the mine itself. Outside the immediate mine area the structure information is not known in detail, nor can it be practically defined.

- Numerical convergence problems often arise when numerous model cells may vary between unsaturated and saturated conditions during the simulation process using MODFLOW. Such problems are especially likely to occur when certain layers or portions of the model are “thinly” saturated. Convergence problems are usually not as significant with the utilization of constant thickness layers or transmissivity based models when using MODFLOW.

Limitations in assuming transmissivity based models for aquifer conditions when an unconfined assumption may be more appropriate include the following:

- There is a tendency to over-predict drawdown; and

- There is a tendency to over-predict the rate of flow from imposed boundary conditions such as drains or rivers.

In essence, the use of a confined aquifer assumption versus an unconfined assumption generally leads to more conservative results for purposes of estimating the amount of dewatering, and also projecting water level changes associated with coal mining.

Again, portions of the shallower strata, especially in the northern portions of the mine are unsaturated.

Horizontal Discretization

The model grid structure consists of 259 rows and 464 columns and it is variably spaced. The model cells are uniformly gridded over Rosebud Mine Areas A, B, C and E. This spacing is 250 feet. Those model cells on the periphery of the model domain possess larger spacing up to 2,500 feet. The maximum aspect for the rows (delta-y) is 10. The maximum aspect ratio for the columns (delta-x) is also 10. The aspect ratio represents the overall maximum dimension to minimum dimension for a given model cell. Generally, it is desirable to keep the aspect ratio less than 10 to ensure accuracy during the numerical simulation process. Outside the mine permit areas described above the cell dimensions are gradually increased. No aspect ratio of one cell adjacent to another exceeds a value of 1.5 which is in conformance with requirements of MODFLOW. This again, ensures accuracy will be maintained in the model simulation effort.

Boundary Conditions

The following were the primary boundary condition modules used:

- A majority of the model perimeter is along intermittent or ephemeral streams and/or Rosebud Creek. The goal here is to assign boundary condition water

levels deemed reasonably consistent with natural conditions. The remoteness of these boundaries eliminates any undue influence of artificial boundary conditions on the model calibration and model application efforts. For additional details, see Figure GM-18.

- All stream features are represented using the drain package. It should be emphasized that the “streams” in the vicinity of the Rosebud Mine are ephemeral and rarely flow. The lone exception is Rosebud Creek as it does possess perennial flow. Note that drain cells were assigned relatively low conductance which varies by model cell depending upon the length of the reach within a given cell. For smaller ephemeral drainages, for modeling purposes, the drain width was assigned as 4 feet, thickness as 2 feet, and the hydraulic conductivity as 5 ft/d. For larger drainages, the drain width was assigned as 8 feet, thickness as 2 feet and the hydraulic conductivity as 10 feet. Given that many of these drains represent dry alluvium and dry stream reaches, there was no attempt to calibrate drain conductances. A cross-reference to drain assignments is given at the end of Model Attachment GM-C.

As stated before, drains represent sinks associated with mining progress (e.g., mine passes) over time. For model simulation purposes, the drain width was assigned as 50 feet, the drain thickness as 2 feet and the hydraulic conductivity was set at 1 feet per day.

In one instance, site reconnaissance activity indicated that a livestock well is pumped continuously on a seasonal basis (from May through December) near alluvial observation well WR-231. Hence, in this instance, a well boundary condition is used to represent this pumping well.

2.1.5 Areal Sources/Sinks

Again, the source of flux into the model was application of water via the recharge package (RCH). The actual overall rate of recharge is very low as most precipitation is

low. Certain fractions of this precipitation are also lost to the evapotranspiration. Other fractions outflow at shallow springs from perched zones in the overburden. Hence, such water does not become deeper recharge to the lower portions of the overburden, or to underlying strata.

Therefore, the focus of this model is to define “net recharge” as that flow that ultimately reaches the hydrogeologic units of interest, namely the deeper overburden, Rosebud coal, interburden, McKay coal and sub-McKay. This rate and amount of “net recharge” ultimately reaching the underlying hydrogeologic stratum, on average, is very low.

The rate of recharge varies substantially in the area of the mine. It is likely that much greater recharge occurs at clinker zones (Heffern and Coates, 1999). Similarly, flows along drainages also act to provide greater recharge. Recharge may also be relatively higher in the immediate vicinity of major faults, or in areas of historic mining disturbance. Locally, higher recharge may also occur beneath stock ponds and mine sediment control ponds. In some instances, where relatively more permeable strata outcrop, recharge rates may be relatively higher as well.

There were no additional areal sources or sinks included in the model structure other than those defined previously.

3.0 MODEL CALIBRATION PROCESS

The model calibration process included using the statistical evaluation packages contained in GV. Two hundred and seventeen wells served as steady-state calibration targets (see Table GM-1).

3.1 Results

3.1.1 Statistical Summary

Table GM-2 provides a summary of the calibration results. Table GM-3 provides a layer-by-layer calibration summary. The following are the basic statistics presented in th Table GM-2:

- Residual mean is 0.19 feet. A residual is the difference between the observed potentiometric head (well water level) and the computed potentiometric head. The residual mean is the average of the residuals for all observation points. This mean represents the tendency of the model to either over-predict or under-predict water levels. Since the residual mean is very small (positive), there is very-slight tendency to under-predict observed well water levels when the steady-state model simulation results and data are evaluated as a whole.
- Residual standard deviation is 11.75 feet. This statistic is simply the standard deviation representing the dispersion of model residuals computed.
- The sum of squares is 29977.27. The sum of squares is the sum of each residual squared. In effect, the smaller this value the better the model fit. The size of this value is also dependent upon the number of observation points.
- Absolute residual mean is 9.03 feet. The absolute residual mean represents the magnitude of the difference between the measured water levels and the simulated water levels. The absolute residual mean was the primary statistic employed during the model calibration process and the goal was to minimize the value of this statistic.

- The minimum residual is -36.88 feet (negative implies over prediction) at WO-184. In effect, it states that actual water level (target) is 36.88 feet lower than the simulated value.
- The maximum residual was 30.11 feet at WM-121. This is the equivalent of stating that the actual water level (target) is 30.11 feet higher than the simulated value. Note that this well is not in the immediate vicinity of the area of interest.
- The scaled absolute residual mean is 0.017. This statistic assists in determining if the calibration is adequate. According to James Rumbaugh, developer of Groundwater Vistas, a typical modeling effort should obtain a value less than 0.1. Based upon this criterium, the model provides an excellent fit to the observation data.

Note that the relative ability to obtain a calibration fit is constrained significantly by the high degree of vertical head differences, including at the local scale, between the various hydrostratigraphic units.

Figure GM-19 provides the simulated potentiometric heads for each model layer. . Plates GM-B1 and GM-B2 given in Attachment GM-B provide comparisons between interpretative water level contours and simulated contours for the Rosebud and McKay coals respectively. Figures GM-20 and GM-21 provide graphical comparisons between observed and simulated water level observations. Figure GM-20 presents all the calibration data on one plot. Figure GM-21 presents the calibration results on a layer-by-layer basis. The upper plots compare the observed potentiometric head values with the simulated potentiometric heads. These plots demonstrate that the model reasonably represents the observed potentiometric heads.

The lower plots of Figures GM-20 and GM-21 compare the residuals to the observed potentiometric heads. If such a plot indicates a trend in the residuals, then it may indicate possible areas for model improvements. Since the residuals are randomly

distributed, there is little basis for substantively changing the model to improve the model calibration.

Figure GM-22 provides an area-wide depiction of residuals for each model layer.

Upon evaluating area-wide residuals, one of the more difficult areas for matching existing water levels extended was at the west edge of Area B, and at/near the southwestern and west portions of Area Cfor model layer 4 (representing the McKay coal). The tendency in this area was to over-predict groundwater levels in layer 4. The magnitude of this impact was reduced somewhat by decreasing the transmissivity of the McKay coal to the southwest of Areas B and C, yet, the tendency to over-predict for the McKay coal in this area could not be fully eliminated. The same trend for over-prediction in this portion of the mine was not observed in model layers 1 through 3. One possible explanation for this issue being primarily isolated to the McKay coal is the presence of faults in this area of the Rosebud Mine. Given that the McKay coal is thinner (~8 feet) than the Rosebud coal (~26 feet), it is possible that the McKay has been offset to the degree that the lateral hydraulic communication along this hydrogeologic unit is more likely affected for a given fault. As the Rosebud coal is thicker, hydraulic communication along the Rosebud may not be affected. However, the actual physical factor(s) that could explain the anomaly for water levels in this portion of the model for the McKay coal is (are) unknown.

The model also produces results which are reasonably representative of the vertical hydraulic gradients that are present in the strata at and near the Rosebud Mine. This is evident via the layer-by-layer statistics presented in Figure GM-21. Furthermore, Table GM-5 provides comparisons of vertical water levels at several well groups. In some instances, the model over-predicts the vertical differences and in other cases it under-predicts the vertical differences. A comparison of the average differences at the end of Table GM-5 indicates that the average difference from the upper simulated unit

compared to the lower simulated unit shows a slight underprediction of the vertical gradient with the simulation model. However, much of this difference is attributable to two clustered well series. One of these is the series WR-173, WI-173 and WM-173 while the other is the series WO-178, WR-121, WI-178, and WM-178. In general, it is deemed that the simulation model provides a reasonable depiction of the vertical gradients when the mine area is considered as a whole.

Based upon Tables GM-3 and GM-5 and Figures GM -20 through GM-22, the calibrated model provides a reasonable depiction of hydrogeologic conditions for Areas A, B and C. of the Rosebud Mine area.

3.1.2 Model Parameter Zonation

Figure GM-23 provides calibrated transmissivity and leakance estimates for the vicinity of the Rosebud Mine. Generally, the calibrated transmissivity values for the Rosebud mine model are reasonably consistent with the data collected during the 1982 EIS (see Figure GM-8).

Figure GM-24 presents recharge estimates applied in the modeling effort. Note that consistent with the conceptual model, and research of others, relatively higher recharge rates were applied in areas of mapped clinker deposits, and along the Little Wolf Mountain drainage divide, and in the base of drainages. Generally, relatively greater precipitation occurs in elevated areas along the Little Wolf Mountains. In addition, these ridges tend to be capped with clinker. Hence, it is rational to assume that greater recharge would occur in areas where greater precipitation occurs and where clinker is present. It is also rational to assume that runoff events would lead to recharge in the drainages. Another area where relatively higher recharges are applied includes Area E, which represents a historically mined area. The logic of this assumption is that the presence of low permeability layers does not exist, allowing more infiltration and vertical seepage to underlying strata. Given that the historic mining occurred in much of Area E

in the 1950s, it is assumed that groundwater levels have nearly fully recovered in those portions that were mined historically.

3.1.3 Volumetric Budget

Model Domain

Table GM-4 presents the mass balance results from the MODFLOW simulation. A low mass balance difference of 0.0024 percent was obtained. For the model simulation, the model fluxes for the aquifer system were quantified to be the following:

- Recharge (represents areal recharge) [10.42 cubic feet per second (cfs)]; and

- Drain Flux (from drain cells representing ephemeral drainages creeks, alluvial deposits in such drainages, etc.) [10.42 cfs]. Stock well (GWIC ID 1056) was at 0.01 cfs.

3.1.4 Steady-State Model Sensitivity Analysis

The steady-state model sensitivity analysis is provided in Attachment GM-C. The following summarizes the conclusions of that sensitivity analysis:

- The steady-state model is sensitive to transmissivity for the viable range of this parameter in the model domain.
- The model is sensitive to changes in recharge.
- The model is sensitive to changes to vertical leakance, and, in effect, the composited vertical hydraulic conductivity.
- The model shows low sensitivity to drain conductance.

It is noted as well, that in conducting the sensitivity analysis, some limited improvements in the calibration statistics could be obtained in some instances. However, it is deemed

that none of these would result in any substantive improvement in overall predictive capability.

4.0 MODEL APPLICATION PROCEDURE/TRANSIENT EVALUATION AND RESULTS

A conceptual representation of the transient representation of the mining process is given in Figure GM-25. The simplified mining progression in Area A, B and C for the 1975 through 2020 existing permits is presented in Figure GM-26.

Following the completion of the steady-state model calibration process, a series or cascade of MODFLOW models was created in order to represent the following mining phases:

- Past mining from 1975 through 2011. (Areas A, B, and C)
- Future mining - in Areas A, B and C from 2012 through 2020 as specified in the existing permits.

For simulations representing mining activity, the focus of the transient simulations was on the relative changes in water levels and the projected formation dewatering rates.

A transient evaluation was performed by varying storativity and comparing simulated drawdown results with observed drawdown results at selected wells at the mine. Subsequently, representative storativity values were applied to project future mining system response.

4.1.1 Procedure

The impacts of the mine dewatering process were represented using the Drain Package of MODFLOW. The drains were added sequentially to represent the effect of mining passes. Following a given mine pass, the drains were removed.

The parameters of the model cells used to represent spoils were adjusted to values representative of mine spoils. In essence, a series of BCF modules were created with

the only difference being the updated formation parameters in accordance with the mining activity progress (see Figure I-26). The updated parameters representing the spoils were as follows:

- Transmissivity was assigned to 13 ft^2/day.
- Vertical leakance was not changed between the layer representing the spoils and the underlying model layer under the assumption that the primary factor leading to impedance of vertical leakage from the coals and spoils was due to the underlying mudstone/under-clays which are typically of low to extremely low permeability.
- The initial storativity was assumed to be 0.01 for all layers of the model except for the spoils which was assigned a storativity of 0.1.
- Recharge in the spoils was assigned as 0.00005 ft/day or 0.22 inches per year. This is a conservative recharge rate for projecting future water level recovery rates.

In addition, model layer 1 was inactivated at the end of each mine pass since the overburden and Rosebud coal were removed (two layers) and replaced by mine spoils (one layer).

4.1.2 Storativity Analysis

One of the factors influencing the model's drawdown predictions is the storage coefficient or storativity (S) associated with each model layer. The storativity is defined as the volume of water that is released or taken into storage per unit surface area, per unit of head change (Todd, 1980). Storativity typically decreases as conditions become more confined.

The Rosebud Mine model focused on testing a limited range of storativities for historic observations (1975-2011) via the following scenarios:

- Scenario 1 – Storativities were set to:
    - S of layer 1 through 5 was set to 0.01
    - S of spoils in layer 2 was set to 0.1
- Scenario 2: Storativities were set to:
    - S of layer 1 was set to 0.01
    - S of layer 2 through 5 was set to 0.001
    - S of spoils in layer 2 set to 0.1

Figure GM-27 (page 1 and 2) presents observed and simulated drawdown for both scenarios in selected Rosebud coal and McKay coal wells throughout Rosebud Mine. As expected, the results show that decreasing S from 0.01 to 0.001 for layers 2 through 5 increased the predicted drawdown for the given layer. This resulted in a slightly better fit for most McKay coal wells, but generally led to a poorer fit for the Rosebud wells when compared to Scenario 1. Thus, it is demonstrated that assigning a storativity of 0.01 to model layer 2 yields more representative drawdown for the Rosebud Coal. Figure GM-27 (page 1) shows that Scenario 1 generally approximates observed drawdown values within 5 to 10 feet.

Another means of comparison is provided in Table GM-6. This table shows a comparison or the difference between observed and simulated drawdown at the selected Rosebud and McKay coal wells defined above. Note the following:

- Scenario 1 assumptions underpredicted the drawdown by an average of 3.95 feet.
- Scenario 2 assumptions overpredicted the drawdown by an average of 3.45 feet.
- Scenario 3 assumptions overpredicted the drawdown by an average of 1.42 feet.

It is deemed that Scenario 3 is the most representative of the three scenarios that were evaluated. It is also provides for conservative results as it slightly over-predicts

observed drawdown at the mine. Subsequently, the following storativities (Scenario 3) are used in the Rosebud Mine groundwater model:

- S = 0.1, assigned to alluvium (layer 2) and spoils (layer 2)
- S = 0.01, assigned to overburden (layer 1) and Rosebud coal (layer 2)
- S = 0.001, assigned to interburden (layer 3), McKay coal (layer 4) and sub-McKay (layer 5).

The model simulation results using the above parameters are provided in Figure GM-27 (pages 3 and 4). As this figure demonstrates, the model simulations reasonably represent observed drawdown for the Rosebud coal (see page 3).

One primary factor that may explain why a storativity of 0.01 produces representative drawdown results in the Rosebud coal is given by Van Voast and Reiten (1988, page 11) as quoted below:

> "The presence of thick sand beds in the Rosebud overburden supports the possibility of greater storage coefficients for a combined coal and sand-bed aquifer at that locale."

Note that the locale under reference is at the southern edge of Area B. In other words, the Rosebud coal in this portion of the mine tends to be unconfined due to the presence of the sandstone overlying this coal. Observation wells WR-162 and WR-164, more recently installed, also show the presence of siltstone/sandstone overlying the coal. Hence, Van Voast and Reiten were insightful in their assessment of the possibility of higher storativities for the Rosebud coal simply because substantial portions of the strata immediately overlying this coal are not true confining layers.

All storativity tests conducted using the prior model and the existing model lead to under prediction of drawdown for the McKay coal in some southern portions of Area B. For instance, refer to wells WM-161, WM-162 and WM-164 (Figure GM-27, page 4). It

should be noted that assigning lower storativities (e.g., 0.0001) to layers 3 through 5 was tested in an attempt to improve the fit for this area of the model. This assignment did not lead to any substantive improvement in simulating drawdown for the McKay coal in this area. It may be that some portion of drawdown can be attributed to Big Sky Mine operations (ceased in December, 2003) which are just south of Area B. On the other hand, the model tends to over-predict drawdown in some other portions of the mine for the McKay coal (e.g., WM-168 and WM-153).

A simulated rate of recovery was calculated for recovering spoils wells in Areas A, B and C. For a list of these wells refer to Table 19 of the PHC. The simulated average rate of recovery for spoils wells in Areas A and B was three and six inches/year, respectively. The model does not predict any recovery in Area C spoils well WS-121 for the period of record. The observed average rate of recovery for Areas A and B is 4 and 11 inches/year, respectively. Hence, the projected rate of recovery using the model is reasonably similar to that of the observations for Area A. Note that some standing water in the Area high-wall pits likely leads to the slightly higher observed recovery rate of 4 inches in the spoils compared to the simulated recovery of 3 inches per year.

The recovery rate in the vicinity of Area B is much higher than is predicted by the model. Much of the reason for this difference is believed to be a combination of historically leaky PPL ponds and standing water in high-wall pits. Note that each of these contributions cannot be practically accounted for without more information.

It is expected that as mining concludes, the simulated and observed recovery rates will become more similar with time.

In summary, based upon the information to date, the model simulations tend to produce conservative results in terms of groundwater level recovery.

4.1.3 Flow Evaluation

Area A, B, and C

In order for the model to be representative of the hydrogeologic media and the mining process, it should also provide reasonable predictions of discharge. Conversations with Rosebud Mine staff have yielded opinions that discharges from the geologic media in the main mine area tend to be about 100 gallons per minute in given active mine areas. Much higher flow rates were observed when WECo mined near the E. Fork Armells Creek alluvium. The amount of water that needs to be managed is a function of the total length of the active mine passes as well.

Table GM-7 provides a summary of the simulated groundwater extractions due to mining in Areas A, B and C. Review of Table GM-7 shows:

- Mining in Area A is projected to yield the smallest discharges with annual average mining discharge ranging from 4 to 103 gallons per minute (gpm). The simulated cumulative average is 39 gpm.
- Mining in Area B is projected to yield the largest discharges ranging with annual average mining discharge ranging from 25 to 422 gpm. The simulated cumulative average is 143 gpm.
- Mining in Area C is projected to yield annual average mining discharges ranging from 2 to 229 gpm. The simulated cumulative average is 107 gpm.

The following is noted with respect to these simulated flow rates:

- Actual instantaneous and longer-term flow rates will vary depending upon how the mine manages the water that enters the pits. In some instances, water may be pumped from one pit to another.
- Discharge rates during actual pumping may be much higher, and last for relatively shorter durations than a year.
- Some portion of the discharge likely enters the spoils during the mining process.
- There are likely to be anomalies, such as the presence of the alluvium or faults bounding, or in the proximity of mine passes.

- There are climatic factors as well, including evaporation, and impacts of major precipitation/runoff events which can add water to these pits.

In effect, it is possible that locally higher temporal discharges will be encountered in areas of the mine that bound the alluvium that are not apparent in the simulation results set forth in Table GM-7. These locally higher temporal discharges are likely to more apparent during initial mining activity in those areas bounding alluvium.

4.1.4 Projected Changes in Water Level

The following figures present simulated potentiometric heads in Rosebud coal (page 1) and McKay coal (page 2):

- Figure GM-28: simulated potentiometric head at the end of 2011.
- Figure GM-30: simulated potentiometric head as a result of existing permit mining activities in Areas A, B and C, at the end of 2020.

Simulated drawdown in the Rosebud coal (page 1) and McKay coal (page 2) is presented in the following figures:

- Figure GM-29: simulated drawdown at the end of 2011.
- Figure GM-31: simulated drawdown as a result of existing permit mining in Areas A, B and C, at the end of 2020.

5.0 SUMMARY AND CONCLUSIONS

The following summarize the results of this groundwater modeling effort:

- The model provides a conservative and consistent basis for comparing the hydrologic response of the relative impacts to the groundwater associated with mining in the proposed disturbance area.

- The steady-state calibrated model utilizes hydraulic parameters, namely transmissivity values, that are consistent with data defined in the EIS (1982).

- The model is sensitive to changes in transmissivity over the likely range of values for this parameter in the mine vicinity. The model is most sensitive to leakance (or vertical hydraulic conductivity) and recharge. Low values of leakance and low rates of recharge were generally required to match both discharge rates and water levels.

- The model consistently represents water level observations over time. In addition, transient simulations demonstrated that the model provided discharge rates reasonably consistent with observations.

- The Rosebud Mine model predicts that a majority of the impacts will arise in the within the permit boundary. Impacts to the water levels in areas outside the mine boundary are projected to be much smaller. The most significant drawdowns outside the mine are projected to occur near southern portions of Area B.

6.0 LIMITING ASSUMPTIONS OF THE MODELING EFFORT

There are limiting assumptions that should be noted when applying this flow model including the following:

- Models are predictive tools and they represent simplifications of complex systems.

- The model assumes each saturated zone for all layers is of constant thickness. The actual saturated zones are of variable thickness spatially and temporally.

- The mine stress periods assume a stress is instantaneously applied at each drain used to represent mine passes. In reality, the mine passes develop more gradually over time.

- There is uncertainty about the magnitude of various formation parameters including hydraulic conductivity (transmissivity), leakance, storativity, porosity and recharge rates.

- There is no unique modeling solution to a complex natural system. In essence, there are alternative conceptual and hydraulic models which could be applied to Rosebud Mine area.

AVERAGE ALL TARGETS		**-3.95**	**3.45**	**1.42**

Notes

(a) If this difference is positive, the model overpredicts drawdown. If the difference is negative the model underpredicts drawdown.

(b) Scenario 1: storativity in all layers was set to 0.01.
Scenario 2: storativity was kept at 0.01 in layer 1 and set to 0.001 in layers 2-5.
Final model: storativity in was set to 0.01 layer 1 and 2 and 0.001 in layer 3 through 5.
The storativity of the spoils in all cases was set to 0.1.

Exhibit 8

LEGEND

Fort Union Formation - Sandstone
Predominantly light yellow-brown where weathered to grey and light grey where unweathered. Fine to very fine grained silty sandstones. Frequently massive where numerous crossbedded channel sequences are stacked and interbedded. May contain pyrite or hematite concretions and disseminated pyrite.

Fort Union Formation - Mudstone with Thin Sandy Interbeds
Predominantly sandy mudstone with thin bands to lenses of intercolated very fine sand material representing transition from lower energy to higher energy deposits.

Fort Union Formation - Mudstone
Predominately grey to dark grey, silty to sandy claystone with sparse to moderate carbonaceous content. Commonly includes dark to very dark carbonaceous clay intervals with notable pyrite content.

Fort Union Formation - Coal (Rosebud and McKay Beds)
Predominantly hard, brittle, dull, subbituminous coal with some mudstone bands and laminations. Sparse to abundant secondary pyrite, most common near top and bottom contacts with enclosing sediments. "Where burned near outcrops forms baked and fused material in overlying units." Often poor and soft where exposed to oxidation by near surface weathering.

Adapted from EXHIBIT_Q3_GEO_XSEC_200111026 for conceptual illustration purposes, i.e., the potentiometric heads and perched zones should be considered conceptual only.

A- *Recharge at surface.*
B- *Infiltration/percolation to lower strata.*
C- *Potential perched zones*
D- *Potentiometric head, Rosebud coal (RC).*
E- *RC potentially locally confined by overlying mudstone*
F- *RC potentially locally unconfined by presence of overlying sandstone.*
G- *Potentiometric head, McKay coal.*

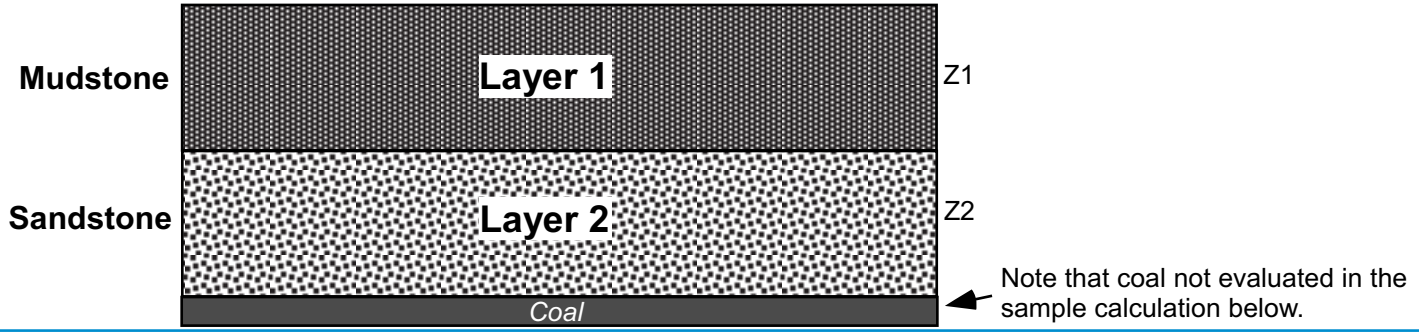
Conceptualization of Vertical Groundwater Leakage Overburden to Rosebud Coal

Figure GM-4

Exhibit 8

A

Conceptual two layer model with layers of identical thickness ($z_1 = z_2$).



Assume that $K_v = 0.1K_h$ **B**

Furthermore, assume that K of mudstone is about the same as shale. According to Delft Design Manual (Hydrology Project, Government of the Netherlands (2003)), a representative value of hydraulic conductivity for shale is 10^{-7} m/day or 3.28×10^{-7} ft/day.

Applying these assumptions yields the following vertical and horizontal conductivity values.

$K_{x1} = 3.28 \times 10^{-7}$ ft/d; ***$K_{z1} = 3.28 \times 10^{-7}$*** ft/d (note that no vertical anisotropy is assumed for the mudstone).

$K_{x2} = 3$ ft/d; ***$K_{z2} = 0.3$*** (note that the vertical to horizontal anisotropy ratio for the sandstone is assumed as 0.1).

According to Todd (1980), a classic groundwater hydraulics reference, the equivalent horizontal hydraulic conductivity of n layer system can be defined as follows:

$$Kx = \frac{K_1z_1 + K_2z_2 + \ldots . K_nz_n}{z_1 + z_2 + \ldots .+ z_n}$$ **C**

Furthermore, according to Todd, the equivalent horizontal hydraulic conductivity of n layer system can be defined as follows:

$$Kz = \frac{z_1 + z_2 + \ldots .+ z_n}{z_1/K_1 + z_2/K_2 + \ldots .+ z_n/K_n}$$ **D**

E===>

For the example above, and assuming a two layer model and applying the relationships from Todd (**C** and **D**), this would yield the following respective effective horizontal and vertical hydraulic conductivities:

K_x = 1.50 feet per day (the effective horizontal hydraulic conductivity of the two-layer system)

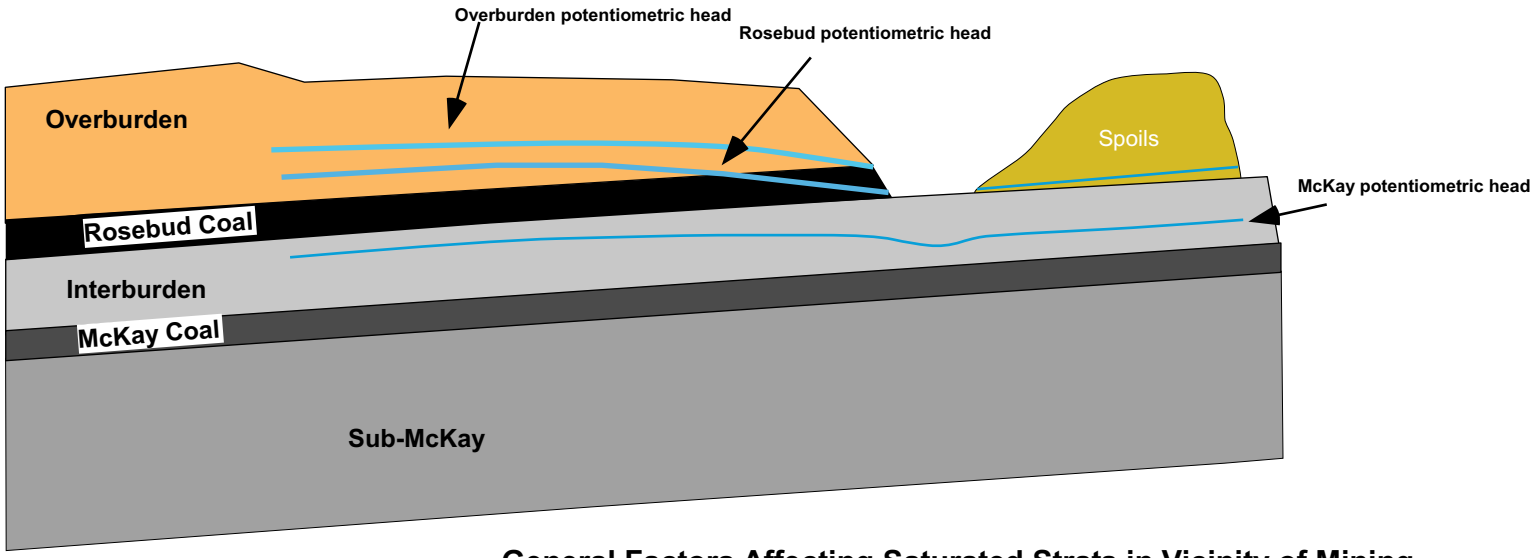
$K_z = 6.56 \times 10^{-7}$ feet per day (the effective vertical hydraulic conductivity of the two-layer system)

or the effective vertical anistropy ratio (K_z/K_x) is 4.37×10^{-7}.

Note that in the event if either of the vertical to horizontal anisotropy ratios exhibited in **A** and **B** were smaller, then each of the latter two values would be smaller accordingly.

Date: April 23, 2013 d://figure GM-5 By: MEN Issued for Western Energy	NICKLIN EARTH & WATER, INC.	**Conceptual Illustration Defining Effective Hydraulic Conductivities and Vertical Anisotropy Ratio Multilayer Geologic Unit**	Figure GM-5

Exhibit 8



General Factors Affecting Saturated Strata in Vicinity of Mining

1. Saturated portions of Overburden and Rosebud Coal are dewatered during mining. Hence, ground-water levels for exposed strata near the mine pass decline.
2. Some change in potentiometric head may be induced in the underlying McKay coal.
3. Any such change is dependent upon the degree of vertical hydraulic conductivity of the interburden which defines the connectivity between the Rosebud Coal and the McKay Coal.
4. Ground-water levels will begin to recover in the remaining spoils after mining proceeds onward.

Hydrogeologic Unit	Discharge Capacity	Transmissivity (ft^2/d)				Storage Coefficient
		Low	High	Mean	Median	
Alluvium (Armells Creek)	Moderate yields	0.8	10,000	1,680	1,324	[0.1 to 0.3]
Overburden	Low to very low yields	0.13	10,600	1,200	7.6	[.006 to 0.03]
Rosebud Coal	Low to very low yields	0.4	1,700	70	4	[0.000015; inapplicable for gravity drainage].
Interburden	Low to very low yields	0.13	28	5.75	0.94	[no data in EIS]
McKay Overburden		30.8	348	201	76	[no data in EIS]
McKay Coal	Low yields	0.13	74.9	19.65	13.9	[no data in EIS]
Sub-McKay	Low yields	12	428	115	62.3	[no data in EIS]
Spoils	Low to very low yields	0.2	3,130	267	8.2	[no data in EIS, assume from 0.1 to 03.]

Parameter values in table adapted from Environmental Impact Statement for Area C, Block I Mine (Montana Department of State Lands, August 2, 1982).

Steady-State Calibration Targets - Rationale of Individual Target
Rosebud Mine

Name	Layer	Observed	Date	Rationale
AAL51	1	3220.00		*
AOVM73	1	3309.00		*
BOV1012	1	3256.80		*
BOV112	1	3373.20		*
BOV1712	1	3257.00		*
BOV212	1	3363.50		*
BOV512	1	3318.50		*
BOV612	1	3313.00		*
WA-103	1	3389.20	7/25/1979	Selected as representative of series WA-102 through WA-106
WA-116	1	3273.40	22-May-80	First readings predated mining.
WA-117	1	3276.00	22-May-80	First readings predated mining.
WA-118	1	3648.59	22-Aug-85	Remote from mining - representative of WA-119 through WA-121
WA-122	1	3472.80	4-Dec-80	Early water levels stable until mining encroached nearer area.
WA-123	1	3474.40	4-Dec-80	Early water levels stable until mining encroached nearer area.
WA-171	1	3530.21	1-Sep-82	Well is drought responsive. Has not responded to mining and is upgradient from mining. Likely vertically isolated from Rosebud coal with underlying overburden strata.
WA-209	1	3456.55	21-Mar-88	Early record is pre-date mining. Mining began in area in 1992 and the well responded to this mining.
WA-210	1	3455.56	22-Sep-88	Early record is pre-date mining. Mining began in area in 1992 and the well responded to this mining.
WA-214	1	3524.91	26-Jul-85	Outside vicinity of mining. Dramatic increase in water levels observed in response to 2011 major precipitation event. Note that initial modeling pre-dated the later observations.
WA-216	1	3543.83	8/5/1985	Observations pre-date mining. Could have selected WA-215 as an alternative target as has longer period of record, or could have employed both.
WA-224	1	3558.56	12/21/2012	New well. Far from any mining activity. Added after initial modeling effort.
WA-226	1	3511.97	12/21/2012	New well. Far from any mining activity. Added after initial modeling effort.
WA-227	1	3472.21	12/21/2012	New well. Far from any mining activity. Added after initial modeling effort.
WO-101	1	3386.60	22-May-80	Water level data before any mining in area of this well.
WO-103	1	3462.95	22-May-80	Water levels showing some decline before mining in area but not as pronounced as WO-102.
WO-107	1	3463.79	5-Aug-85	Water levels predate mining in the vicinity of this well.
WO-108	1	3464.33	5-Aug-85	Water levels predate mining in the vicinity of this well.
WO-155	1	3450.85	24-Nov-81	Water levels showing some limited decline before mining in area occurred.
WO-156	1	3457.27	23-Nov-81	Water levels stable before mining in vicinity.
WO-162	1	3385.90	1-Sep-82	First water levels predate mining in vicinity. This observation well appears to have responded to mining indicating that it is hydraulically connected to the Rosebud coal.
WO-164	1	3403.05	15-Dec-90	First water levels predate mining in vicinity. This observation well appears to have responded to mining indicating that it is hydraulically connected to the Rosebud coal.
WO-165	1	3469.84	1-Sep-82	First water levels predate mining in vicinity. This observation well appears to have responded to mining indicating that it is hydraulically connected to the Rosebud coal.
WO-166	1	3472.81	1-Sep-82	First water levels predate mining in vicinity. This observation well appears to have responded to mining indicating that it is hydraulically connected to the Rosebud coal.
WO-168	1	3483.15	1-Sep-82	First water levels predate mining in vicinity. This observation well appears to have responded to mining indicating that it is hydraulically connected to the Rosebud coal.
WO-169	1	3462.97	1-Sep-82	First water levels predate mining in vicinity. This observation well appears to have responded to mining indicating that it is hydraulically connected to the Rosebud coal.
WO-172	1	3495.25	1-Sep-82	First water levels predate mining activity. This well may be drought responsive as long term declines observed before mining in vicinity.
WO-176	1	3456.47	5-Mar-84	Well stable and nonresponsive to mining.
WO-178	1	3510.84	5-Mar-84	Early readings showed slight increasing trend over time. This may indicate a very low yield well. Water levels stablized just above 3510 as time progressed.
WO-179	1	3467.40	2-Mar-84	First water levels predate mining activity. This well may be drought responsive.
WO-181	1	3483.20	2-Mar-84	First water levels predate mining activity. This well has been unresponsive to mining to date.
WO-184	1	3482.23	15-Jan-05	First readings predate mining in area. Dramatic increase in water level in association with 2011 precipitation, runoff and recharge event.
WO-185	1	3535.27	14-Feb-05	First readings predate mining in area. Slight increase in water level in association with 2011 precipitation event.
WO-186	1	3542.34	12-Jan-05	No mining in area. Well showed some response to 2011 precipitation event.
WO-187	1	3507.58	15-Jan-05	No mining in area.

WR-101	2	3304.40	30-Jun-79	First readings before mining in this well's vicinity. First value is highly anomalous.
WR-102	2	3319.80	21-Dec-79	First readings before mining in Area B. Showed seasonal variation in association with E. Fork Armell's Creek alluvium.
WR-103	2	3490.30	13-Jul-81	First readings before mining in vicinity. Readings beginning just after 2000 may be indicating a resonse to mining in Area C and Area B.
WR-112	2	3434.98	29-Sep-88	Observations predate mining in area. Well appears to be drought responsive.
WR-113	2	3440.88	30-Aug-84	Observations predate mining in area. Well appears to be drought responsive.
WR-115	2	3465.80	4-Dec-80	Observations predate mining in area.
WR-116	2	3401.10	5-Oct-79	Observations predate mining in area.
WR-117	2	3457.00	5-Oct-79	Observations predate mining in area.
WR-121	2	3470.91	28-Apr-82	Drought responsive well. Many wells in thsi portion of the system are drought responsive.
WR-122	2	3444.79	28-Sep-87	Observations predate mining in area. Well appears to be drought responsive.
WR-124	2	3499.28	3-Sep-91	Observations predate mining in area. Well appears to be drought responsive.
WR-125	2	3494.15	22-Sep-92	Observations predate mining in area and well about one mile upgradient of any current mining. Well appears to be drought responsive.
WR-126	2	3449.10	21-Oct-80	First observations predate mining in area and well about one mile upgradient of any current mining. Well appears to be drought responsive.
WR-154	2	3465.06	24-Nov-81	Very first observations predate mining in area.
WR-156	2	3450.62	23-Nov-81	Very first observations predate mining in area.
WR-161	2	3333.54	27-Aug-82	Very first observations predate mining in area.
WR-162	2	3384.34	30-Aug-82	Very first observations predate mining in area.
WR-164	2	3404.05	1-Sep-82	Very first observations predate mining in area.
WR-168	2	3483.01	8-Apr-85	Revaluate the target value for this well. More representative values may be from about 1985.
WR-169	2	3459.82	1-Sep-82	First observations predate mining in area.
WR-173	2	3480.83	1-Sep-82	Observations predate mining in area and well about one mile upgradient of any current mining. Well appears to be drought responsive. Re-evaluate target value in future modeling.
WR-181	2	3457.91	25-Sep-87	First observations predate mining in area.
WR-205	2	3286.33	26-Jan-83	Mining commenced near this well after first readings. Possible some very limited drawdown from mining to the east of this well.
WR-208	2	3292.44	26-Jan-83	Mining commenced near this well after first readings. Possible some very limited drawdown from mining to the east of this well.
WR-215	2	3296.33	26-Jan-83	Mining commenced after very first observations at this well.
WR-227	2	3316.26	25-Jan-83	Very first observations predate mining in Area B.
WR-229	2	3453.01	4-Sep-02	Observations predate mining in Area.
WR-231	2	3458.94	15-Jan-05	No mining in area at time of construction. Later readings may be responding to mining in Area C.
WR-233	2	3505.42	15-Jan-05	No mining in area. Well appears to be drought responsive. Reacts significantly to major precipitation/runoff events.
WR-234	2	3496.44	15-Jan-05	No mining in area. Well appears to be drought responsive. More recent data indicate an increase in water levels with increase in precipitation.
WR-236	2	3517.06	15-Jan-05	No mining in area. Well appears to be drought responsive. More recent data indicate an increase in water levels with increase in precipitation. Well adjacent to model no-flow boundary
WR-237	2	3477.61	14-Feb-05	No mining in area. Well appears to be drought responsive. More recent data indicate an increase in water levels with increase in precipitation. Well adjacent to model no-flow boundary
WR-239	2	3525.66	15-Jan-05	No mining in area. Well appears to be drought responsive. Reacts significantly to major precipitation/runoff events.

Steady-State Calibration Targets - Rationale of Individual Target
Rosebud Mine

Name	Layer	Observed	Date	Rationale
BIN517	3	3318.00		*
BIN617	3	3296.50		*
BIN717	3	3241.50		*
WA-192	3	3370.66	5-Mar-84	Well is remote from mining. It is likely that this well is drought responsive. Representative of Wel WA-191.
WA-194	3	3353.16	2-Mar-84	Well is remote from mining. It is likely that this well is drought responsive. Representative of wells WA-193 through WA-196 and WA-218.
WA-204	3	3333.85	31-Jul-84	Well is remote from early mining. Did not respond to mining in later period of observations. Representative of WA-205 which possesses a shorter period of record.
WI-104	3	3444.60	22-May-80	Mining began near this well about two years after mining began.
WI-107	3	3239.54	07/07/88	East of Area E. No obvious overall upward or downward trend.
WI-153	3	3449.13	18-Dec-81	First observations before mining began in 1984. Very first reading appears to be anomalous.
WI-154	3	3461.68	18-Dec-81	First observations before mining began in area. Very first reading appears to be anomalous.
WI-155	3	3421.17	22-Dec-81	First observations before mining began in area. Very two readings appear to be anomalous.
WI-156	3	3444.55	23-Nov-81	First observations before mining began in area.
WI-161	3	3331.27	~~30-Aug-82~~	Early readings pre-date mining.
WI-162	3	3386.64	1-Sep-82	Early readings pre-date mining.
WI-163	3	3399.98	1-Sep-82	Early readings pre-date mining in this vicinity of Area B.
WI-164	3	3409.22	1-Sep-82	Early readings pre-date mining in this vicinity of Area B.
WI-165	3	3451.81	1-Sep-82	Early readings pre-date mining in this vicinity of Area C.
WI-166	3	3437.18	1-Sep-82	Early readings pre-date mining in this vicinity of Area B.
WI-167	3	3435.36	1-Sep-82	Early readings pre-date mining in this vicinity of Area C.
WI-168	3	3444.27	1-Sep-82	Early readings pre-date mining in this vicinity of Area C.
WI-169	3	3436.38	1-Sep-82	Early readings pre-date mining in this vicinity of Area C.
WI-172	3	3458.82	1-Sep-82	Early readings pre-date mining in Area C and Area B. Long trem decline especially beginning in late 1980s a concern in using this well as a target. Re-evaluate in future model simulations.
WI-173	3	3464.41	1-Sep-82	Early readings pre-date mining in Area B to the north. Long-term declines for all wells in this cluster. Potentially drought responsive series.
WI-176	3	3419.40	5-Mar-84	Unresponsive to mining.
WI-177	3	3423.92	2-Mar-84	Monitored well before any mining in vicinity.
WI-178	3	3435.88	5-Mar-84	Monitored well before any mining in vicinity. Possibly a drought responsive well.
WI-179	3	3433.78	03/02/84	Monitored well before any mining in vicinity.
WI-180	3	3426.58	03/02/84	Monitored well before any mining in vicinity.
WI-181	3	3452.41	2-Mar-84	Monitored well before any mining in vicinity. Possibly a drought responsive well.

WA-220	4	3404.58	1/12/2005	New well. Far from any mining activity. Added after initial modeling effort.
WM-100	4	3364.80	30-Jun-79	First observations predate mining.
WM-102	4	3319.40	19-May-79	Well predates mining in general vicinity. Well also exhibits a "dampened" correlation to changing water levels in E. Fork Armells Creek alluvium (see WA-101).
WM-106	4	3281.20	19-May-79	First observations predate mining.
WM-108	4	3429.00	19-May-79	First observations predate mining. Alternative steady state target values could be employed.
WM-109	4	3417.22	24-Oct-84	First observations predate mining. Alternative steady state target values could be employed. Note that first values appear as anomalous and hence not used as target value.
WM-111	4	3423.30	5-Oct-79	First observations pre-date mining. Well appears to be drought responsive.
WM-113	4	3438.40	22-Aug-95	First observations pre-date mining. It is reasonable to use a higher target, say 3438.40 associated with August 22. 1985.
WM-114	4	3430.90	17-Nov-79	First observations predate mining.
WM-122	4	3208.50	11-Jun-09	Mining before well installed. Distance to well greater so post-mine recovery is very limited and also indicates a limited radius of influence to Area E mining. Re-evaluate in future simulations.

Steady-State Calibration Targets - Rationale of Individual Target
Rosebud Mine

Name	Layer	Observed	Date	Rationale
WM-127	4	3226.35	8/16/1995	Historic mining before well installed. Assumed recovery is full.
WM-136	4	3228.12	28-Aug-85	Near mined area but well seemed to have recovered by mid to late 1980s. Adjusted to slightly higher target value.
WM-138	4	3226.58	8/16/1995	Historic mining before well installed. Assumed recovery is full.
WM-153	4	3432.91	18-Dec-81	First two years of readings predate mining in Area.
WM-154	4	3433.78	18-Dec-81	First two years of readings predate mining in Area. First two readings anomalous
WM-155	4	3418.82	22-Dec-81	First observations predate mining in well vicinity. Note that first observation is anomalous.
WM-156	4	3421.90	23-Nov-81	First two years of readings predate mining in Area.
WM-161	4	3314.20	30-Aug-82	Very first observations predate mining in this portion of Area B.
WM-162	4	3386.70	1-Sep-82	Very first observations predate mining in this portion of Area B.
WM-163	4	3399.86	1-Sep-82	First observations predate mining.
WM-164	4	3408.15	1-Sep-82	First observations predate mining. Possible combined effects of drawdown associated with mining Area B and Peabody coal.
WM-165	4	3442.91	28-Sep-82	First observations predate mining in vicinity. First observation anomalous and readings in 1987 and 1988 anomalously high.
WM-167	4	3419.89	1-Sep-82	First observations predate mining in Area.
WM-168	4	3440.85	28-Sep-82	First observations predate mining in Area.
WM-169	4	3424.11	1-Sep-82	First observations predate mining in Area.
WM-173	4	3420.61	1-Sep-82	First observations predate mining in Area.
WM-176	4	3399.09	20-Apr-94	Most observations predate mining in Area.
WM-178	4	3409.06	5-Mar-84	Most observations predate mining in Area.
WM-179	4	3411.36	2-Mar-84	First observations predate mining in Area.

WA-109	5	3218.60	26-Sep-79	Selected as representative of series WA-107 through WA-109
WA-135	5	3149.30	21-Apr-81	Target is remote and in Cow Creek drainage
WA-142	5	3166.74	28-Jan-83	Target is remote and in Cow Creek drainage
WA-145	5	3187.50	17-Sep-82	Target is remote and in Cow Creek drainage
WA-152	5	3202.05	25-Aug-82	Water level is stable - outside of immediate mining area - representative of wells WA-149 through WA-152.
WA-153	5	3145.08	25-Aug-82	Water level is stable - outside of immediate mining area. Redundant well is WA-154.
WA-156	5	3127.44	27-Sep-82	Water level is stable - outside of immediate mining area - representative of wells WA-155 through WA-158.
WA-161	5	3171.63	25-Aug-82	Early water levels stable - outside immediate mining area - representative of wells WA-159 through WA-161.
WA-165	5	3272.37	5-Oct-83	Well is drought responsive - outside of mining area for early readings - possible response to mining beginning in late 1980s. Represents WA-164 through WA-166.
WA-168	5	3295.64	27-Jul-84	Well is drought responseive. Outside of mining for early readings. Representative of response at WA-167 which has a much shorter period of record.
WA-169	5	3373.07	30-Aug-82	Well is drought responsive. Response of nearby well WA-170 is nearly identical with shorter period of record.
WA-183	5	3229.78	2-Mar-84	Early readings relatively steady. Likely a drought responsive well. Representative of wells WA-182 through WA-188.
WA-198	5	3132.60	2-Mar-84	Well was remote from mining during observation period. It is likley that this well is drought responsive. Representative of wells WA-197 through WA-201.
WA-219	5	3357.40	5/31/2005	New well. Far from any mining activity. Added after initial modeling effort.
WA-221	5	3377.71	1/12/2005	New well. Far from any mining activity. Added after initial modeling effort.

Steady-State Calibration Targets - Rationale of Individual Target
Rosebud Mine

Name	Layer	Observed	Date	Rationale
WA-225	5	3357.97	12/20/2012	New well. Far from any mining activity. Added after initial modeling effort.
WD-100	5	3262.00	19-May-79	Water level data before mining in area. Responded to mining - fault may be a factor.
WD-104	5	3175.30	15-May-80	Well appears to be unresponsive to mining in Area E. It is possible that later readings are showing signs of recovery. Re-evaluate in future model simulations.
WD-174	5	3202.35	28-Sep-01	Later value used assuming nearly full recovery. Revaluate for future model simulations.
WD-189	5	3449.39	15-Jan-05	Water levels show slight increasing trend, especially after major precipitation event in 2011.
WD-192	5	3439.87	15-Jan-05	Well remote from mining activity. Considered pre-mine well.
WD-193	5	3427.62	15-Jan-05	Well remote from mining activity. Considered pre-mine well.
WD-194	5	3385.77	15-Jan-05	Well remote from mining activity for first observations. Considered pre-mine well.
WA-131		3262.41	13-Sep-05	Later water level used assuming recovery. Re-evaluate this well for future simulations.
WA-141		3286.83	3-Dec-81	Well assumed as unresponsive to mining. Re-evaluate this well for future simulations for potential of mining impacts.
WD-185		3314.61	29-Aug-85	Installed after historic mining. Revaluate this well for future simulations for potential of mining impacts.
WD-186		3344.97	29-Sep-85	Installed after historic mining. Revaluate this well for future simulations.
WI-106		3226.86	3-Jun-09	Later value used assuming nearly full recovery. Revaluate for future model simulations.
WI-117		3286.87	06/11/09	Used a later value assuming nearly full recovery. Revaluate with future modeling efforts.
WI-174		3244.50	24-Nov-82	Earliest readings pre-date permitted mining in Area E. Re-evaluate for future model simulation efforts.
WI-182		3232.96	12-Dec-08	Used a later value assuming nearly full recovery. Revaluate with future modeling efforts.
WM-120		3225.34	30-Jun-09	Used a later value assuming nearly full recovery. Revaluate with future modeling efforts.
WM-121		3248.30	30-Jun-09	Used a later value assuming nearly full recovery. Revaluate with future modeling efforts.
WM-184		3278.68	24-Jan-00	Mining before well installed. Note that a later value used after hydrograph stabilized indicating recovery had occurred. Re-evaluate with future modeling efforts.
WR-100		3277.50	19-Mar-79	Well sceened just above Rosebud Coal in sandstone. Re-evaluate will in future model simulations.

1.0 INTRODUCTION

1.1 Background

The Rosebud Mine in southeastern Montana has been in operation since 1975 (Figure E-1). Western Energy Coal Company (WECo) is proposing an expansion of the existing mining permit in the eastern portion of Area B, designated as AM4 (Amendment Application 00184). Figure E-2 presents the historical and projected timing of the mine passes for both the existing permit and the proposed amendment. The figure shows that mining within the existing permit of Area B is projected to conclude in 2020. The proposed AM4 mining cuts are anticipated to be mined from 2013 to 2026. This report presents the results of a groundwater modeling effort to evaluate potential changes in groundwater quantity associated with the AM4 Amendment.

In 2011, Nicklin Earth & Water developed a regional groundwater model for the Rosebud Mine area. The model was updated and revised in 2013 and is hereafter designated as the "Rosebud Mine Groundwater Model". A brief overview of the model is given below; however, refer to the Rosebud Mine Groundwater Model Report, provided as Attachment D, for a detailed description of model development, calibration and structure, as well as the hydrologic, geologic and hydrogeologic data used to develop the model.

The current modeling effort makes use of the regional Rosebud Mine model to simulate historical and planned mining within the existing permit in Areas A, B and C. More specifically, mining progression is simulated using a set of cascading transient models for which the regional Rosebud Mine model is the basis.

1.2 Model Overview

The Rosebud Mine groundwater model was developed using MODFLOW: "A modular three-dimensional finite difference ground-water flow model developed by the United States Geological Survey [USGS]" (McDonald and Harbaugh, 1988).

The model domain encompasses an area of approximately 27 miles (N-S) by 36 miles (E-W). The model uses a variable spaced grid, however, a uniform grid density was applied to areas of permitted mining.

The hydrogeology was represented in the model using five layers assigned a constant saturated thickness. The model layers generally represent the following geologic strata:

- Layer 1: Alluvium and overburden
- Layer 2: Rosebud coal
- Layer 3: Interburden
- Layer 4: McKay coal
- Layer 5: SubMcKay

The model parameters (transmissivity, recharge and leakance) were modified areally during calibration to achieve as reasonable an approximation to pre-mining potentiometric head as feasible. Generally, the calibrated transmissivity values for the Rosebud mine model are reasonably consistent with data collected during the EIS (1982). For a detailed overview of steady-state model parameters, refer to the Rosebud Mine Groundwater Model Report.

1.3 Model Application Procedure / Transient Evaluation

The calibrated steady-state model described above was used as the basis of a series of cascading, annual MODFLOW models. The series of models was developed to represent the following mining phases in Areas A, B and C:

- Historic mining from 1975 through 2012 for Areas A, B and C. These models were created as part of the Rosebud Mine Groundwater Model (Attachment D).
- Scenario 1: existing permits

  - Future mining of the existing permits for Areas A, B and C, starting with the year 2013 through 2026. Mining of the existing permit in Area B is projected to conclude in 2020.

  - Post mining starting at the end of mining in 2026 and extending to 2076. This post-mine model simulation was run to 50 years in the future to evaluate the long-term response following mining completion.

- Scenario 2: proposed permit

  - Future mining of the proposed permit from 2013 through 2026. The proposed permit consists of mining of the AM4 Amendment passes in addition to the existing permits for Areas A, B and C. The AM4 revision passes are projected to be mined from 2013 through 2026 (see Figure E-2).

  - Post mining starting at the end of mining in 2026 and extending to 2076 for the existing permit and proposed AM4 Amendment. This post-mine model simulation was run to 50 years in the future to evaluate the long-term response following proposed mining in Area B in addition to mining of existing permits.

A detailed description of the transient modeling process is presented in the Rosebud Mine Groundwater Model Report (Attachment D). In essence, the mine dewatering process in any given year is simulated by inserting drains at the location of the planned mining passes for that year. In the next year's model, these drains are removed and a new series of drains are added.

In addition to the use of drains to simulate the mining progression, changes are made in model formation parameters. Mining in Areas A, B and C includes the removal of the Rosebud coal seam (model layer 2) which is generally overlain by overburden (model layer 1). Once an area is mined, the top layer of the model is inactivated in the corresponding mining footprint. Next, the model parameters of the second model layer in the same area are changed to represent the spoils which replace the mined overburden and coal. The model formation parameters that change are hydraulic conductivity, storativity and recharge.

2.0 RESULTS

2.1 Pre-mining

The pre-mine potentiometric heads as simulated by the steady-state model are presented in Figure GM-19 of the Rosebud Mine Groundwater Model Report. Generally, the direction of groundwater flow within Area B is southeast to northeast. Simulated pre-mine steady-state potentiometric heads in the Rosebud coal (layer 2) and McKay coal (layer 4) were used as a reference to calculate the drawdowns presented in Figures E-3, E-4, E-7 and E-8 of this report.

2.2 During Mining

Simulated mean annual discharge rates and cumulative average discharge rates from 1977 through 2026 for Area B for both the existing and proposed permit are presented in Table E-1. The cumulative average discharge in Area B for the proposed permit is 141 gpm. Comparison of discharge rates for the proposed permit with discharge rates for the existing permit shows that the proposed permit is predicted to increase the average annual discharge rate in Area B during the 2013-2020 period by 44 gpm.

The Rosebud Mine Groundwater Model Report stated that the following should be noted with respect to the discharges calculated by the models:

- Actual flow rates will vary depending on how the mine manages the water that enters the pits. In some instances, water may be pumped from one pit to another.
- Discharge rates during actual pumping may be much higher, and last for relatively shorter durations than a year.
- Some portion of the discharge likely enters the spoils during the mining process.
- There are likely to be anomalies, such as the presence of alluvium that bounds the projected mine cuts or faults that are not easily represented in this regional model.
- There are climatic factors, including evaporation, and impacts of major precipitation/runoff events which can add water to these pits.

2.3 End of Proposed AM4 Mining - 2026

The AM4 Amendment is projected to be mined from 2013 through 2026. This section discusses drawdown simulation results at the end of 2026.

Figures E-3 and E-4 show the simulated drawdown in the vicinity of Area B in 2026 as a result of mining the existing permit and proposed AM4 Amendment, for the Rosebud coal and McKay coal, respectively. The model projects that the most substantial drawdown as a result of mining in Area B will occur within the existing permit boundary and its immediate vicinity. The largest simulated drawdown at the end of the proposed permit is about 110 feet and is projected to occur in the Rosebud coal in the eastern part of Area B, near the southern permit boundary. As is to be expected, the maximum projected drawdown in the Rosebud coal is higher than the maximum projected drawdown in the McKay coal.

Figures E-5 and E-6 present the difference in simulated potentiometric head in 2026 between the existing and proposed permit for the Rosebud coal and McKay coal, respectively. The figures show that the additional drawdown in Area B as a result of the addition of the AM4 passes is expected to occur within the Area B permit boundary and immediately south of the permit boundary.

2.4 Post Mining - 2076

The simulated residual drawdown 50 years after proposed permit mining in Area B has ceased is shown in Figures E-7 and E-8. In the Rosebud coal in Area B, the maximum residual drawdown is projected to be about 50 feet, whereas the highest simulated residual drawdown in the McKay coal is projected to be about 25 feet, in the eastern portion of Area B, near the southern permit boundary.

Figures E-9 and E-10 present the difference in simulated potentiometric head in 2076, between the existing and proposed permit for the Rosebud coal and McKay coal, respectively. The figures show that the additional drawdown as a result of the addition of the AM4 expansion is localized within the Area B permit boundary and its immediate vicinity. In 2076, the maximum difference in drawdown between the existing and proposed permit is projected to be about fifteen feet and 5 feet for the Rosebud coal and McKay coal, respectively.

3.0 SUMMARY AND CONCLUSIONS

The following summarizes the results of this groundwater modeling effort:

- As stated in the Rosebud Mine Groundwater Model Report, the Rosebud Model provides a conservative and consistent basis for comparing the hydrologic response of the relative impacts to groundwater associated with mining in the proposed disturbance area.

- The projected cumulative average discharges over the period of mining (1977-2026) in Area B are 143 gpm (2020) and 141 gpm (2026) for the existing and proposed permit, respectively.

- The maximum drawdown projected outside of the mine boundary at the end of the proposed permit mining is between 80 and 90 feet in the Rosebud coal just south of the eastern portion of Area B. The five foot drawdown is projected to extend up to 1.8 miles south of Area B.

- Significant residual drawdown is predicted to remain 50 years after proposed mining is completed in Area B. Outside of the mine permit boundary, the maximum residual drawdown is between 40 and 50 feet in the Rosebud Coal just south of the eastern portion of Area B. The residual five foot drawdown contour is projected to extend up to 2.3 miles south of Area B.

- The groundwater model simulations predict that the addition of the AM4 revision will result in additional drawdown of about 40 feet in the Rosebud coal and about five feet in the McKay coal, as evaluated at the end of 2026. In 2076 the maximum difference in drawdown between the existing and proposed permit is projected to be about fifteen feet and five feet for the Rosebud coal and McKay coal, respectively.

1.0 INTRODUCTION

1.1 Background

The Rosebud Mine in southeastern Montana has been in operation since 1975 (Figure E-1). Western Energy Coal Company (WECo) is proposing an expansion of the existing mining permit in the eastern portion of Area B, designated as AM4 (Amendment Application 00184). Figure E-2 presents the historical and projected timing of the mine passes for both the existing permit and the proposed amendment. The figure shows that mining within the existing permit of Area B is projected to conclude in 2020. The proposed AM4 mining cuts are anticipated to be mined from 2013 to 2026. This report presents the results of a groundwater modeling effort to evaluate potential changes in groundwater quantity associated with the AM4 Amendment.

In 2011, Nicklin Earth & Water developed a regional groundwater model for the Rosebud Mine area. The model was updated and revised in 2013 and is hereafter designated as the "Rosebud Mine Groundwater Model". A brief overview of the model is given below; however, refer to the Rosebud Mine Groundwater Model Report, provided as Attachment D, for a detailed description of model development, calibration and structure, as well as the hydrologic, geologic and hydrogeologic data used to develop the model.

The current modeling effort makes use of the regional Rosebud Mine model to simulate historical and planned mining within the existing permit in Areas A, B and C. More specifically, mining progression is simulated using a set of cascading transient models for which the regional Rosebud Mine model is the basis.

1.2 Model Overview

The Rosebud Mine groundwater model was developed using MODFLOW: "A modular three-dimensional finite difference ground-water flow model developed by the United States Geological Survey [USGS]" (McDonald and Harbaugh, 1988).

The model domain encompasses an area of approximately 27 miles (N-S) by 36 miles (E-W). The model uses a variable spaced grid, however, a uniform grid density was applied to areas of permitted mining.

The hydrogeology was represented in the model using five layers assigned a constant saturated thickness. The model layers generally represent the following geologic strata:

- Layer 1: Alluvium and overburden
- Layer 2: Rosebud coal
- Layer 3: Interburden
- Layer 4: McKay coal
- Layer 5: SubMcKay

The model parameters (transmissivity, recharge and leakance) were modified areally during calibration to achieve as reasonable an approximation to pre-mining potentiometric head as feasible. Generally, the calibrated transmissivity values for the Rosebud mine model are reasonably consistent with data collected during the EIS (1982). For a detailed overview of steady-state model parameters, refer to the Rosebud Mine Groundwater Model Report.

1.3 Model Application Procedure / Transient Evaluation

The calibrated steady-state model described above was used as the basis of a series of cascading, annual MODFLOW models. The series of models was developed to represent the following mining phases in Areas A, B and C:

- Historic mining from 1975 through 2012 for Areas A, B and C. These models were created as part of the Rosebud Mine Groundwater Model (Attachment D).
- Scenario 1: existing permits

  - Future mining of the existing permits for Areas A, B and C, starting with the year 2013 through 2026. Mining of the existing permit in Area B is projected to conclude in 2020.

  - Post mining starting at the end of mining in 2026 and extending to 2076. This post-mine model simulation was run to 50 years in the future to evaluate the long-term response following mining completion.

- Scenario 2: proposed permit

  - Future mining of the proposed permit from 2013 through 2026. The proposed permit consists of mining of the AM4 Amendment passes in addition to the existing permits for Areas A, B and C. The AM4 revision passes are projected to be mined from 2013 through 2026 (see Figure E-2).

  - Post mining starting at the end of mining in 2026 and extending to 2076 for the existing permit and proposed AM4 Amendment. This post-mine model simulation was run to 50 years in the future to evaluate the long-term response following proposed mining in Area B in addition to mining of existing permits.

A detailed description of the transient modeling process is presented in the Rosebud Mine Groundwater Model Report (Attachment D). In essence, the mine dewatering process in any given year is simulated by inserting drains at the location of the planned mining passes for that year. In the next year's model, these drains are removed and a new series of drains are added.

In addition to the use of drains to simulate the mining progression, changes are made in model formation parameters. Mining in Areas A, B and C includes the removal of the Rosebud coal seam (model layer 2) which is generally overlain by overburden (model layer 1). Once an area is mined, the top layer of the model is inactivated in the corresponding mining footprint. Next, the model parameters of the second model layer in the same area are changed to represent the spoils which replace the mined overburden and coal. The model formation parameters that change are hydraulic conductivity, storativity and recharge.

2.0 RESULTS

2.1 Pre-mining

The pre-mine potentiometric heads as simulated by the steady-state model are presented in Figure GM-19 of the Rosebud Mine Groundwater Model Report. Generally, the direction of groundwater flow within Area B is southeast to northeast. Simulated pre-mine steady-state potentiometric heads in the Rosebud coal (layer 2) and McKay coal (layer 4) were used as a reference to calculate the drawdowns presented in Figures E-3, E-4, E-7 and E-8 of this report.

2.2 During Mining

Simulated mean annual discharge rates and cumulative average discharge rates from 1977 through 2026 for Area B for both the existing and proposed permit are presented in Table E-1. The cumulative average discharge in Area B for the proposed permit is 141 gpm. Comparison of discharge rates for the proposed permit with discharge rates for the existing permit shows that the proposed permit is predicted to increase the average annual discharge rate in Area B during the 2013-2020 period by 44 gpm.

The Rosebud Mine Groundwater Model Report stated that the following should be noted with respect to the discharges calculated by the models:

- Actual flow rates will vary depending on how the mine manages the water that enters the pits. In some instances, water may be pumped from one pit to another.
- Discharge rates during actual pumping may be much higher, and last for relatively shorter durations than a year.
- Some portion of the discharge likely enters the spoils during the mining process.
- There are likely to be anomalies, such as the presence of alluvium that bounds the projected mine cuts or faults that are not easily represented in this regional model.
- There are climatic factors, including evaporation, and impacts of major precipitation/runoff events which can add water to these pits.

2.3 End of Proposed AM4 Mining - 2026

The AM4 Amendment is projected to be mined from 2013 through 2026. This section discusses drawdown simulation results at the end of 2026.

Figures E-3 and E-4 show the simulated drawdown in the vicinity of Area B in 2026 as a result of mining the existing permit and proposed AM4 Amendment, for the Rosebud coal and McKay coal, respectively. The model projects that the most substantial drawdown as a result of mining in Area B will occur within the existing permit boundary and its immediate vicinity. The largest simulated drawdown at the end of the proposed permit is about 110 feet and is projected to occur in the Rosebud coal in the eastern part of Area B, near the southern permit boundary. As is to be expected, the maximum projected drawdown in the Rosebud coal is higher than the maximum projected drawdown in the McKay coal.

Figures E-5 and E-6 present the difference in simulated potentiometric head in 2026 between the existing and proposed permit for the Rosebud coal and McKay coal, respectively. The figures show that the additional drawdown in Area B as a result of the addition of the AM4 passes is expected to occur within the Area B permit boundary and immediately south of the permit boundary.

2.4 Post Mining - 2076

The simulated residual drawdown 50 years after proposed permit mining in Area B has ceased is shown in Figures E-7 and E-8. In the Rosebud coal in Area B, the maximum residual drawdown is projected to be about 50 feet, whereas the highest simulated residual drawdown in the McKay coal is projected to be about 25 feet, in the eastern portion of Area B, near the southern permit boundary.

Figures E-9 and E-10 present the difference in simulated potentiometric head in 2076, between the existing and proposed permit for the Rosebud coal and McKay coal, respectively. The figures show that the additional drawdown as a result of the addition of the AM4 expansion is localized within the Area B permit boundary and its immediate vicinity. In 2076, the maximum difference in drawdown between the existing and proposed permit is projected to be about fifteen feet and 5 feet for the Rosebud coal and McKay coal, respectively.

3.0 SUMMARY AND CONCLUSIONS

The following summarizes the results of this groundwater modeling effort:

- As stated in the Rosebud Mine Groundwater Model Report, the Rosebud Model provides a conservative and consistent basis for comparing the hydrologic response of the relative impacts to groundwater associated with mining in the proposed disturbance area.

- The projected cumulative average discharges over the period of mining (1977-2026) in Area B are 143 gpm (2020) and 141 gpm (2026) for the existing and proposed permit, respectively.

- The maximum drawdown projected outside of the mine boundary at the end of the proposed permit mining is between 80 and 90 feet in the Rosebud coal just south of the eastern portion of Area B. The five foot drawdown is projected to extend up to 1.8 miles south of Area B.

- Significant residual drawdown is predicted to remain 50 years after proposed mining is completed in Area B. Outside of the mine permit boundary, the maximum residual drawdown is between 40 and 50 feet in the Rosebud Coal just south of the eastern portion of Area B. The residual five foot drawdown contour is projected to extend up to 2.3 miles south of Area B.

- The groundwater model simulations predict that the addition of the AM4 revision will result in additional drawdown of about 40 feet in the Rosebud coal and about five feet in the McKay coal, as evaluated at the end of 2026. In 2076 the maximum difference in drawdown between the existing and proposed permit is projected to be about fifteen feet and five feet for the Rosebud coal and McKay coal, respectively.

Exhibit 8

Table E-1
Simulated Mine Discharge Rates Over Time
Rosebud Mine - Area B

Year	Area B - Existing Permit			Area B - Proposed Permit		
	Discharge*	Discharge*	Cumulative Average Discharge**	Discharge*	Discharge*	Cumulative Average Discharge**
	ft^3/d	gpm	gpm	ft^3/d	gpm	gpm
2021				18840	98	150
2022				14290	74	148
2023				14306	74	147
2024				13767	72	145
2025				17832	93	144
2026				4452	23	141

Notes
The bold and italicized years are the years during which the proposed changes occur.
No data are given for years during which no discharge occurred in the area.

* Mean simulated discharge
**Cumulative is calculated per mine area and does not include non-mining years (or areas of no active mine passes).

Notes

(a) Groundwater users within 3 miles downgradient and one mile upgradient from A, B, C permit boundaries

(b) Types
D = Domestic
I/C = Industrial or Commercial
M = Municipal
MW = Monitoring Well
P/O = Private or Other
S = Stock

(c) Two public datasets from the National Resource Information System (NRIS) were consulted: GWIC wells and Water Rights Data
Mined out wells were removed from the selection. When enough data was available (well depth and completion/priority date) duplicate entries were merged.

(d) Completion or priority date.

Exhibit 8

East Fork Armells Creek Hydrological Model

The hydrologic model inputs for Tables G-1, G-2, G-3, G-4, and G-5 are for a single basin model of East Fork Armells Creek from the headwater to the Highway 39 overpass with the characteristics shown in Exhibits 1 and 2. Contours and channels for the premine model were created from premine Digital Terrain Model (DTM) for Mine Areas A, B, and C from their respective approved permits tied to contours and channels digitized from USGS outside the bounds of the DTM. Contours and channels for the post mine were created from DTM for Mine Areas A, B, and C from their respective approved permits tied to premine DTM and digitized USGS contours and channels outside the bounds of the DTM.

TABLE G-1

PREMINE AND POSTMINE GEOMORPHIC CHARACTERISTICS FOR EAST FORK ARMELLS CREEK FROM HEADWATER TO HIGHWAY 39 CROSSING

Drainage Basin	Drainage Area (sq-mi)	Basin Slope[1] (ft/mi)	Drainage Basin Length[2] (ft)	Elon-gation Ratio[3]	Basin Relief[4] (ft)	Basin Perimeter (ft)	Basin Relief Ratio[5] (ft/ft)	Relative Relief[6] (ft/ft)	Total Stream Length[7] (mi)	Drainage Density[8] (mi/sq-mi)	Main Channel Length (ft)	Channel Sinuosity[9] (ft/ft)	Elevation Difference[10] (ft)	Channel Slope[11] (%)	Valley Length (ft)
Armells Creek Pre	34.412	687	74517	0.019	1530	196403	0.021	0.008	115.26	3.35	127634	1.87	1350	1.06	68394
Armells Creek Post	34.560	685	74517	0.019	1530	205919	0.021	0.007	120.08	3.47	127634	1.87	1350	1.06	68394

Notes:

1 Mean basin slope (ft/mi) = [contour interval(ft)][length of contours (mi)] / [drainage area (sq-mi)].
2 Drainage basin length represents the straight line distance from the divide above the dominant channel to the basin mouth.
3 Elongation ratio = (diameter of a circle having the same area as the drainage basin) / (drainage basin length).
4 Basin relief represents the elevation difference between the highest point on the basin boundary and the basin mouth.
5 Basin relief ratio = (basin relief) / (drainage basin length).
6 Relative relief = (basin relief) / (basin perimeter).
7 Total stream length represents the total discernible channel length within the individual drainage, as determined from base and postmine topography interpretation
8 Drainage density = (total stream length) / (drainage area).
9 Channel sinuosity = (channel length) / (valley length).
10 Channel slope represents the overall slope of the main channel as determined by: channel slope = (elevation difference) / (channel length).
11 Valley length represents the length of the surveyed main channel from its surveyed head to the basin mouth, excluding meanders.

TABLE G-2

COMPARISON OF PREMINE AND POSTMINE DRAINAGE BASIN CHARACTERISTICS AND FLOOD RESULTS FOR EAST FORK ARMELLS CREEK FROM HEADWATER TO HIGHWAY 39 CROSSING

Drainage	Drainage Area (sq-mi)		Watercourse Length (ft)		Elevation Difference (ft)		100-yr, 24-hr Peak Discharge [1] (cfs)		100-yr, 24-hr Runoff Volume [1] (ac-ft)		100-yr, 6-hr Peak Discharge [1] (cfs)		100-yr, 6-hr Runoff Volume [1] (ac-ft)	
Basin	Premine	Postmine	Premine	Postmine	Premine	Postmine	Premine	Postmine	Premine	Postmine	Premine	Postmine	Premine	Postmine
Armells Creek	34.41	34.56	127,634	127,634	1350	1350	801.6	805.1	2092.0	2101.1	274.2	275.4	691.1	694.1

Notes:

1 Runoff volumes and peak discharges were computed by the Hydrology Module for SurvCADD Software using the SCS Type II precipitation distribution.

TABLE G-3

PREMINE AND POSTMINE RUNOFF CALCULATIONS FOR EAST FORK ARMELLS CREEK FROM HEADWATER TO HIGHWAY 39 CROSSING

Drainage	Drainage Area (sq-mi)		2-yr, 24-hr Peak Discharge [1] (cfs)		2-yr, 24-hr Runoff Volume [1] (ac-ft)		10-yr, 24-hr Peak Discharge [1] (cfs)		10-yr, 24-hr Runoff Volume [1] (ac-ft)		25-yr, 24-hr Peak Discharge [1] (cfs)		25-yr, 24-hr Runoff Volume [1] (ac-ft)	
Basin	Premine	Postmine	Premine	Postmine	Premine	Postmine	Premine	Postmine	Premine	Postmine	Premine	Postmine	Premine	Postmine
Armells Creek	34.41	34.5600	46.7	49.9	130.5	131.1	278.8	280.0	731.8	734.9	462.6	464.6	1210.9	1216.2

Notes:

1 Runoff volumes and peak discharges were computed by the Hydrology Module for SurvCADD Software using the SCS Type II precipitation

Exhibit 8

TABLE G-4

PEAK PREMINE DISCHARGES OF EAST FORK ARMELLS CREEK FROM HEADWATER TO HIGHWAY 39 CROSSING, CALCULATED FROM OMANG (1992) REGIONAL FLOOD FREQUENCY EQUATIONS

Drainage Basin	Drainage Area (sq-mi)	Mean Basin Elev, E [1] (ft)	Premine Peak Flows (in cfs) for the Given Flood Recurrence Interval Below [2]					
			2 yrs	5 yrs	10 yrs	25 yrs	50 yrs	100 yrs
Postmine								
Armells Creek	34.41	3715	82.5	238.5	403.8	693.2	954.2	1273.3
Postmine								
Armells Creek	34.56	3711	83.0	239.7	405.8	696.7	958.8	1279.4

Notes:

1 Mean basin elevation was determined from a 25-ft grid using SurvCADD software.

2 Taken from: Omang (1992). USGS Water-Resources Investigation Report 92-4048.

FLOOD FREQUENCY EQUATIONS BASED ON BASIN CHARACTERISTICS

Recurrence Interval	Mathematical Equation	Standard Error
2 years	$537\ A^{0.55}(E/1000)^{-2.91}$	128
5 years	$1350\ A^{0.53}(E/1000)^{-2.75}$	85
10 years	$2050\ A^{0.52}(E/1000)^{-2.64}$	70
25 years	$3240\ A^{0.51}(E/1000)^{-2.55}$	59
50 years	$4160\ A^{0.50}(E/1000)^{-2.47}$	56
100 years	$5850\ A^{0.50}(E/1000)^{-2.51}$	58

A = Drainage Area
E = Mean Basin Elevation

TABLE G-5

COMPARISON OF RUNOFF ESTIMATING TECHNIQUES FOR EAST FORK ARMELLS CREEK FROM HEADWATER TO HIGHWAY 39 CROSSING

Drainage Basin	CN [1]	2-yr, 24-hr Peak Discharge (cfs)			10-yr, 24-hr Peak Discharge (cfs)			25-yr, 24-hr Peak Discharge (cfs)		
		SCS [2]	Omang [3]	% Change	SCS [2]	Omang [3]	% Change	SCS [2]	Omang [3]	% Change
Premine										
Armells Creek	69	46.7	82.5	76.9	278.8	403.8	44.8	462.6	693.2	49.9
Postmine										
Armells Creek	69	49.9	83.0	66.4	280.0	405.8	44.9	462.6	696.7	50.6

Notes

1 This is the curve number that was used in the SCS method of runoff determination.

2 These values were calculating using the Hydrology Module for SurvCADD Software, a computer adaptation of the SCS triangular hydrograph method of runoff calculation. See Table 3.

3 These values were calculated using Omang (1992), which estimates peak flow magnitude using regional flood-frequency equations based on drainage basin characteristics. See Table 4.

Comments:

DATA MATRIX
Biological Data

Comments: Not enough data available to conclude anything about the fishery. Macroinvertebrates sampled at 3 sites in 2005. Very few animals were collected at the lower site, indicating thermal extremes or periodic dewatering. The dominant taxon was a tolerant dragonfly. Emergent macrophytes probably provided a significant portion of the habitat space. Nutrient enrichment was suggested at the middle and upper sites. Periodic dewatering may have influenced the biology at the middle site. Blackfly larvae made up 52% of the sample at the middle site, while midges made up 44% of the upper site. Filamentous algae may have been prevalent at the upper site. At least 2 sites suggested poor biotic communities. The chlorophyll a value at all 3 sites was below criteria.

Data Type	Comments	Catalog Number	Citation
fish	No fishery data.	Common.General.DR 8	Montana Department of Fish, Wildlife, and Parks (1999), Montana Rivers Information System (MRIS)
fish	2005: 2 sites visited in 2003 were dry (RM 7.2 and 42.8). RM 24.8 to 24.9 sampled in 2003, no fish captured. RM 19.2 to 19.3 sampled in 2001, 2 Plains Killifish captured.	Common.General.DR 8	Montana Department of Fish, Wildlife, and Parks (2006), Montana Rivers Information System (MRIS): Montana Fisheries Information System (MFISH) - http://maps2.nris.mt.gov/scripts/esrimap.dll?name=MFISH&Cmd=INST

Upper

Data Type	Comments	Catalog Number	Citation
chlorophyll	Upper: 0.30 mg/m^2.	Common.General.DR 8	(2005), DEQ Field Assessment Form
macroinvertebrates	Upper: Midges (44%) dominated the sample. Orthocladius sp. was also among the taxa here; together, these midges suggest that filamentous algae may have been prevalent. Nutrient enrichment is implied. Overall taxa richness (28) was marginal; instream habitat diversity may have been limited. 4 specimens of Dubiraphia sp. were collected, making it less likely that dewatering or thermal extremes affected the biota. Bramlett's IBI score = 33.75%,	Common.General.DR 8	(2005), DEQ Field Assessment Form

Data Type	Comments	Catalog Number	Citation
	indicating poor water quality.		

Lower and Middle

Data Type	Comments	Catalog Number	Citation
chlorophyll	Lower: 0.50 mg/m^2. Middle: 0.50 mg/m^2.	Common.General.DR 8	(2005), DEQ Field Assessment Form
macroinvertebrates	Lower: Very few animals collected here. Low abundance of invertebrates can be an indication of severe habitat disturbance, toxic pollutants, frequent dewatering, or thermal extremes. While metrics may not be used, a few observations about the composition can be ventured. The dominant taxon was the dragonfly Lestes sp., considered a tolerant ordinate. The mayfly Callibaetis sp. was present at the site, suggesting that emergent macrophytes probably provided a significant proportion of instream habitat space. Middle: Blackfly larvae (Simulium sp.) were the dominant taxon collected, accounting for 52% of the animals. The abundance of these animals suggests lotic conditions. Another tolerant taxon, Physa sp., was also present in significant numbers. These taxa suggest that nutrient-rich particulates and algal films were a major energy source in the reach; nutrient enrichment may be indicated. Periodic dewatering may influence the biology, since no less-mobile semivoltine taxa were collected. Bramlett's IBI score = 24.71%, indicating poor water quality.	Common.General.DR 8	(2005), DEQ Field Assessment Form

DATA MATRIX

Habitat Data

Comments: Site visits in 1979 reported stable banks and a channel covered with macrophytes (cattails). 3 sites visited in 2005. The banks were stable vertically and horizontally, and were well vegetated with deep-rooted grasses. The stream had access to a floodplain, and active erosion was minimal. Long, deep glides were prevalent, and the substrate was mostly silt. Macrophyte growth (cattails) is common. Where cattails are not present, sediment moves during major storm events. A lack of trees was noted, but they probably are not required for sustainability. Some rip rap, culverts, and garbage was noted through town. The overall habitat is least or slightly impaired.

From Colstrip to mouth (Armells Creek)

photo points	19 reach photos.	Common.General.DR8	(2005), DEQ Field Assessment Form
riparian &/or instream surveys & physical features	Visited twice in 1979, below Colstrip. 7/79: Banks vegetated and stable. Substrate 40% detritus, 30% muck, 10% gravel, 20% sand/silt. 99% pools. Substrate 90% covered with macrophytes. 3/70: Banks vegetated and stable. Substrate 30% detritus, 30% muck, 40% sand/silt. Substrate 0% covered with macrophytes, mostly bare shifting silt and muck. Lots of cattails.	Lower Missouri.General.DATA	(1981), Field Notes and Data Collected for "Biological Water Quality Monitoring Eastern Montana 1979"
riparian &/or instream surveys & physical features	Stream Reach Assessment: Assessment includes the town of Colstrip. Water first starts "flowing" at Hwy 39, at the So. end of Colstrip, below the mine. The stream appears intermittent through town. No land disturbances were observed from Colstrip to the mouth. In town there were several road crossing, culverts, rip-rap, and bank encroachment. The stream runs through a golf course below town. Stream bottom all silt/clay, abundant submerged vegetation. Long deep glides are prevalent. The lack of trees probably contributes slightly to elevated water temps. There were no noticeable alterations to flow. Aquatic plants consist of rush, sedge, cattails.	Common.General.DR8	(2005), DEQ Field Assessment Form

Data Type	Comments	Catalog Number	Citation
	Some algae growing on submerged veg. Banks appear to be grazed seasonally. Riparian Assessment: Stream appears stable vertically and horizontally. The amount of riparian vegetation is optimal, although the kind of vegetation is sub-optimal (lacks trees and brush). Only a few mature trees are present, although they are probably not required for sustainability. Little erosion observed, the stream has adequate characteristics to dissipate energy. Overall the habitat is in good shape.		

Upper

Data Type	Comments	Catalog Number	Citation
riparian &/or instream surveys & physical features	Upper: Site fairly pristine and appealing. Site is basically a wetland, with a small discernable channel. Water is flowing through cattails. Heavy macrophyte growth, sparse filamentous algae. Substrate 100% silt. No "pools", but channel is deep. No alteration present. Sediment does not move, but covers bottom. Bank stability optimal, only eroded at cow paths, then very little. Bank vegetation protection optimal on RB, sub-optimal on LB (lacking age classes of trees).	Common.General.DR 8	(2005), DEQ Field Assessment Form

Lower and Middle

Data Type	Comments	Catalog Number	Citation
riparian &/or instream surveys & physical features	Lower: Site fairly pristine and appealing. Many minnows observed. Macroinvertebrate Habitat Assessment: Substrate mostly silt, some woody debris, grass, rush. Site is 1 long, deep glide or pool. Channel alteration absent. Banks stable, but	Common.General.DR 8	(2005), DEQ Field Assessment Form

Data Type	Comments	Catalog Number	Citation
	sediment moves w/in channel during major storm events. Bank stability and vegetation protection optimal; grass, brush, scattered adult and young adult trees, forbs. Little evidence of erosion except for a few cow paths. Stream appears to be recovering and a new riparian zone is establishing. Middle: Site somewhat disturbed. Moderate filamentous algae and macrophyte growth. Heavy sedge growth and lots of submerged veg. Macroinvertebrate Habitat Assessment: Substrate mostly silt, some small pebbles; lots of sedge, grass. No "pools" present, reach is a long, narrow, deep glide. Channel alteration absent. Little sediment movement, though the bottom is silt. Bank stability and vegetation protection optimal; no trees or woody vegetation, but good grass cover. With the exception of trees, "as good as it gets" on a prairie stream.

DATA MATRIX

Chemistry Data

Comments: East Fork Armells is typical of most streams in this region. The water is very hard, saline, and high in sulfates. Where TSS data was available (2005), concentrations were low. Mining activities (including water pumped from the Yellowstone River to seeping ponds) likely have contributed to increased TDS concentrations and "water logging" below Colstrip. Water logging may not currently be ocurring. The elevated SC concentrations make this water unsuitable for irrigation under ordinary circumstances. The soils must be permeable, drainage must be adequate, water must be applied in excess, and very salt-tolerant crops should be selected. This water is acceptable for use with livestock accustomed to its use, but is not recommended for pregnant or lactating cows. Data from the 1970's show that NO2+NO3 regularly exceeded criteria, although this was not the case in 2005. In 2005, TKN at the lower site moderately exceeded the contact recreation criteria, and slightly exceeded the aquatic life criteria. At the middle site, contact recreation and aquatic life criteria were slightly exceeded. The most reliable metals data is from the 2005 assessment, which showed no exceedences.

(1977), Hydrogeologic Conditions and Projections Related to Mining Near Colstrip, Southeastern Montana, Bulletin 102
common ions, pH, conductivity, miscellaneous	Water in the East Fork Armells Creek is very hard, alkaline, magnesium sulfate type and has a high concentration of dissolved minerals. Water quality in this stream is poor and is not suited for irrigation, water supply, or most uses. The stream, in its natural state, does not meet States requirement for B-D3 streams to be suitable for growth and propagation of non-salmonid fishes. If the Colstrip flyash pond leaked, it would eventually reach the East Fork of Armells. No measurable impacts are expected due to the stream's poor quality and high flow relative to	Yellowstone.Lower Yellowstone-Sunday.pu130	Botz, Maxwell K. quantitative physical data	More than 8,000 acre-feet per year of Yellowstone river water is pumped to the MPC storage pond to supply the MPC power plant and Colstrip municipal uses. It is evident that a 70% increase in discharges from the Colstrip area have likely resulted in "water logging" problems downstream along EFAC over the past 20 years. Mining activities at this time do not appear to be a contributor to the problem of inundation because mine dewatering has resulted in a reduction of inflow. TDS samples from alluvium	Yellowstone.Lower Yellowstone-Sunday.DR8	Erbes, Dan (1998), Montana Dept. of Environmental Quality Letter to Office of Surface Mining and Reclaimation

ASSESSMENT HISTORY

Cycle 2006

1996- 19 miles listed as partially supporting agriculture, aquatic life, swimmable, and warm water fishery. The causes were nutrients, salinity/TDS/chlorides, and suspended solids. The sources were agriculture, natural sources, and range land. Listed for assessment in 2004 due to insufficient credible data.

Cycle 2008

Not assessed this cycle

Cycle 2010

Not assessed this cycle

Cycle 2012

TKN listing is being changed to a TN listing

Reporting Cycle: 2014 **Assessment Record:** MT42K002_110.pdf **Status:** Unassigned

Cycle 2014

Not assessed this cycle

Overall Condition of Segment

Biology: 1 site was sampled in 2001, and 2 fish were captured. Macroinvertebrates were sampled at 3 sites in 2005. At the lower site, too few animals were collected apply matrices. Of those collected, a tolerant dragonfly was dominant, and heavy macrophyte growth was suggested. The middle and upper sites indicated poor and very poor biotic communities, respectivly. Blackfly larvae made up 52% of the middle site, while midges made up 44% of the upper site. Nutrient enrichment was suggested at both sites. The chlorophyll a value at all 3 sites was below criteria. Habitat: The banks are stable vertically and horizontally. Very little active erosion was noted in 1979 and 2005 assessments. The banks are well-vegetated with deep rooted grasses, and cattail stands are common. Trees are generally lacking, but are not required for sustainability. The substrate is 100% silt. Some channel disturbance was noted through town (culverts, rip rap, a golf course) but not enough to impact the overall impairment level. With the exception of "water logging" (see physical/chemical), the habitat is only slightly impaired.

Physical/Chemical: East Fork Armells is typical of most streams in this region. The water is very hard, saline, and high in sulfates. Where TSS data was available (2005), concentrations were low. Mining activities (including water pumped from the Yellowstone River to seeping ponds) likely have contributed to increased TDS concentrations and "water logging" below Colstrip. DEQ correspondence in 1998 estimated a 50% increase in TDS concentrations in the EFAC alluvium from 1977 to 1997. Water logging may not currently be occurring. The elevated SC concentrations make this water unsuitable for irrigation under ordinary circumstances. This water is acceptable for use with livestock accustomed to its use, but is not recommended for pregnant or lactating cows. Data from the 1970's show that NO2+NO3 regularly exceeded criteria, although this was not the case in 2005.

In 2005, TKN at the lower site moderately exceeded the contact recreation criteria, and slightly exceeded the aquatic life criteria. At the middle site, contact recreation and aquatic life criteria were slightly exceeded. The most reliable metals data is from the 2005 assessment, which showed no exceedences.

Other: TSS does not appear to be an accurate cause of impairment. The macroinvertebrate samples, field observations, and historical and 2005 water chemistry data indicate that nutrients may be a source of impairment. The SC values do not appear to be vastly different from other drainages in the region; however, the probable impact from municipal sources and industrial pond seepage cannot be ignored. The past and present impacts from changes in groundwater chemistry, surface flow, and atmospheric deposition merits further investigation. Salinity/TDS/chlorides will remain a cause of impairment.

Comments: The MBMG is presently doing an assessment to determine the potential impacts of mining to this stream. DEQ will wait until we have the results of that study before making impairment determinations.

DATA MATRIX
Biological Data

Comments: The 1992 and 2005 assessments indicated this segment is ephemeral. Water begins to gather and flow at or near the Hwy 39 bridge, approximately 1/2 mile above the town of Colstrip.

DATA MATRIX

Habitat Data

Comments: Stream is ephemeral. Flow begins at or near hwy. 39. Mining activity (open pit coal) surrounds the stream for much of the reach. A mine employee stated that the mine removed the channel in one section, and may be cutting through another section in the near future. Areas that have been reclaimed are in good condition. The upper 1/4 of the segment is undisturbed pasture land. Bank vegetation consists mostly of grasses and shrubs, trees are mostly missing. There are a number of dikes and road crossings in the channel. Road crossings do not have culverts, apparently due to lack of flow. One pond created by a road crossing is located in the lower section. The affects upon flow from the huge mine pits is unknown, and the mine is continually moving and expanding. Where the mine has not obliterated the channel the stream habitat is not impaired; however, taking into account the mass amount of surrounding land disturbance, the overall habitat is at least moderately impaired. A huge open pit mine cutting through a stream channel is clear evidence of habitat impairment.

Headwaters to Colstrip

Data Type	Comments	Catalog Number	Citation
Land use	The dominant land uses are grazing and mining. Mine activities take place in the lower 3/4's of the stream. The upper 1/4 of the stream is ranch land. Grazing takes place throughout the drainage where land has been reclaimed or is not under construction.	Common.General.DR8	(2005), DEQ Field Assessment Form
photo points	32 photos.	Common.General.DR8	(2005), DEQ Field Assessment Form
riparian &/or instream surveys & physical features	(DR8 Citation: 1992 Stream Reach Assessment Form) Stream ephemeral. Some erosion evident from bank trampling, 10-20% of segment shows erosion. Substrate not measured (no water). Bank vegetation consists of grass with some shrubs and small trees. Little structure in the stream bed to slow water and sediment movement. Some channelization through the town of Colstrip. No flowing or ponded water. Upper reach has dry land farming, with equipment getting as close to banks as possible. Flow began in Colstrip (<1 cfs).	Common.General.DR8	(1997), Pre 1997 Field Assessments
riparian &/or instream surveys & physical	Ephemeral stream. According to locals, stream did not run from top to bottom this year despite the	Common.General.DR8	(2005), DEQ Field Assessment Form

Data Type	Comments	Catalog Number	Citation
features	heavy rains. Some ponded water stands behind a dike in the lower section, which looks to be perennial. This pond is created by the dike and is not natural. There is no culvert in this dike or the many other dikes or road crossings, affirming the ephemeral nature of the stream. There is much land disturbance in the area, but the creek channel itself is undisturbed for the most part. Apparently the mine has bisected the stream in the upper segment. The affects upon flow from this huge open pit mine is unknown. Stream Reach Assessment: Stream is ephemeral from headwaters to near Colstrip (highway 39). Unable to access the upper 2-3 miles of stream (access denied). Could see trees, shrubs, pasture land. A moderate amount of road construction is taking place in the drainage, and the main road crosses the creek in several places. There are numerous dikes in the reach, and there are no culverts at the road crossings or dikes. Most of the drainage is pasture land, and disturbances to the channel are low. A mine employee said the open pit mine cut through the stream channel in one spot, but was unable to confirm on site or through aerial photos. Riparian Assessment: Old downcutting near mouth, but currently stable - stream ephemeral. Laterally stable, and in balance with water and sediment supplied by the watershed. Type and amount of riparian vegetation sub-optimal (lacks trees). Dikes and roads interrupt stream channel. Apparently the flow is not large enough during runoff to require culverts.		

Reporting Cycle: 2014 **Assessment Record:** MT42K002_170.pdf **Status:** Completed

DATA MATRIX

Chemistry Data

Comments: Water chemistry data is limited to a "water hole" and one other site in 1973, a pond in 1980, and one other site in 1985. The "other" sites were located approximately 5 miles above Colstrip. The stream has dried up since 1985, or the samples were taken after a rain event, as this reach is ephemeral. There is nothing in this data to indicate anthropogenic sources of impairment. A 40% increase in TDS in the alluvial aquifer above Colstrip is attributed to mining, and may be impacting the stream below Colstrip.

ASSESSMENT HISTORY

Cycle 2006

1996 - Listed as partially supporting aquatic life, swimmable, and warm water fishery. The causes were nutrients and suspended solids. The sources were agriculture and range land. Listed for assessment in 2004 due to insufficient credible data.

Cycle 2008

Not assessed this cycle

Cycle 2010

Not assessed this cycle

Reporting Cycle: 2014 **Assessment Record:** MT42K002_170.pdf **Status:** Completed

Cycle 2012

Not assessed this cycle

Cycle 2014

Removed 2B category during 2014 cycle.

Overall Condition of Segment

This segment is ephemeral. Water begins to surface in the channel near highway 93. The stream did not run continually from the top to bottom in spring 2005, despite the heavy rains. Some outdated water chemistry data is available from a pond, a "water hole", and an upstream site. Either the upstream site has dried up since then or the sample was taken after a rain event. The samples are of little use, although there was nothing to indicate impairment. The stream was assessed in 2004. The entire reach was dry with the exception of a human-induced pond in the lower segment. This water is backed up behind a bermed road crossing with no culvert. There are several dikes and road crossings in the reach with no ponded water, and the area is currently being mined for coal. At least 2 huge open pits are located near the channel, and a mine employee said one pit crossed the channel. DEQ employees were unable to confirm this, despite accessing almost the entire stream. 2005 aerial photos show the mine enroaching upon, but not entering the stream channel. At least one observed part of the stream was once obliterated by the mine, but has been reclaimed. As the mine is expanding and moving, it is reasonable to assume the mine will continue to impact the stream channel.

Grazing is occurring throughout the reach with little impact. The riparian vegetation is mostly grasses and shrubs. Trees are generally missing, but are not required for sustainability. It is not known if this stream was intermittent prior to mining activities, which began in the 1920's. Mining activity has, at a minimum, moderately impaired the habitat in this segment. This segment should remain listed until mining activity has ceased, and the entire drainage is reclaimed. DEQ protocol requires ephemeral streams only to be assessed for habitat. Because the habitat is impaired, aquatic life is partially supporting, despite the fact the stream is ephemeral. There is insufficient information to evaluate the warm water fishery beneficial use; it does not support the use likely due to natural conditions (category 5N).

Other: There is very little useful data available in this reach for suspended solids. The habitat is impaired from overall mining activity, but there were no sources identified in the 2005 assessment for suspended solids. It appears that TSS was listed in 1996 before the stream was separated into two reaches. Almost all of the historical data is from the lower segment which, unlike the upper segment, is not ephemeral. There is "good cause" for delisting suspended solids as a cause of impairment in this segment.

Attorney for Respondent Department of Environmental Quality

MONTANA BOARD OF ENVIRONMENTAL REVIEW

MONTANA ENVIRONMENTAL INFORMATION CENTER, and SIERRA CLUB, Petitioner, v. MONTANA DEPARTMENT OF ENVIRONMENTAL QUALITY, Respondent.	Case No.: BER 2016-03 SM **RESPONDENT'S RESPONSES TO PETITIONERS' FIRST SET OF REQUESTS FOR ADMISSION, INTERROGATORIES AND REQUESTS FOR PRODUCTION**

Respondent Montana Department of Environmental Quality responds to PETITIONERS' FIRST SET OF REQUIESTS FOR ADMISSION, INTERROGATORIES AND REQUESTS FOR PRODUCTION as follows:

INTERROGATORY NO. 1:

Please identify each person who assisted the answering of these interrogatories.

ANSWER:

The following current employees of DEQ's Industrial and Energy Minerals Bureau: Peter Schade, hydrologist; Martin Van Oort, hydrologist; Melissa Sjolund, technical coordinator/MPDES permit coordinator; Adam McMahon, hydrologist; Robert Smith, permit coordinator; Chris Yde, supervisor, Coal and Uranium Section; Ed Coleman, bureau chief,

Exhibit 5

Industrial and Energy Minerals Bureau. John North, Chief Legal Counsel. Emily Hinz, hydrologist, formerly with the Industrial and Energy Minerals Bureau; now with the Department of Fish, Wildlife, and Parks.

INTERROGATORY NO. 2:

Before answering these discovery requests, state whether or not you have:

A. Made a due and diligent search of all related documents within your possession or under your control, in order to obtain information with respect to this appeal. If not, please explain why.

B. Made a due and diligent inquiry of DEQ personnel, Montana state agency staff, consultants, and officials in order to obtain information with respect to this appeal. If not, please explain why.

ANSWER:

(A) Yes.

(B) Yes as to DEQ personnel. No as to other agencies, consultants, and officials because none would have relevant information.

INTERROGATORY NO. 3.

Please identify all DEQ personnel involved in the Amendment AM4 permit review and/or development process.

ANSWER:

The following current employees of DEQ's Industrial and Energy Minerals Bureau: Peter Schade, hydrologist; Martin Van Oort, hydrologist; Sharona Gilbert, administrative assistant; Ashley Eichhorn, fiscal specialist/project manager; Peter Mahrt, engineer; David Adair, engineer; Julian Calabrese, soil scientist; Mike Glenn, vegetative specialist; Robert Smith,

permit coordinator; Chris Yde, supervisor, Coal and Uranium Section; Ed Coleman, bureau chief, Industrial and Energy Minerals Bureau.

The following former employees of DEQ's Industrial and Energy Minerals Bureau: Tom Golnar, hydrologist, retired; Jim Consort, hydrologist, retired; Emily Hinz, hydrologist, now with the Department of Fish, Wildlife, and Parks; Angela McDannel, hydrologist, retired; Samantha Gundlach, vegetation specialist, now homemaker; Chris Bardash, GIS analyst, now with Texas Department of Transportation; Eric Urban, technical coordinator, now bureau chief, Water Quality Planning Bureau.

INTERROGATORY NO. 4:

Please identify all other Montana state agency staff and officials, not employed by DEQ, and consultants who were involved in the Amendment AM4 permit review and/or development process.

ANSWER: None.

INTERROGATORY NO. 5:

Please identify all documentary evidence relevant to this appeal.

ANSWER: DEQ objects to this interrogatory on grounds it is vague, overly burdensome, and calls for information that is subject to attorney client communication or attorney work product privileges. Furthermore, DEQ cannot determine what documents Petitioner's may assert or the Board of Environmental Review may determine are relevant to this appeal, and Petitioners or the Board may disagree with DEQ's relevance determinations.

REQUEST FOR ADMISSION NO. 1:

You are requested to admit that WECo submitted its Area F permit application in 2011.

ANSWER: Admit.

REQUEST FOR ADMISSION NO. 2:

You are requested to admit that WECo's Area F permit application was pending before DEQ at the time DEQ approved WECo's Amendment AM4 application.

ANSWER: Admit.

REQUEST FOR ADMISSION NO. 3:

You are requested to admit that portions the proposed Area F permit area are within the cumulative hydrologic impact area identified in DEQ's CHIA for Amendment AM4.

ANSWER: DEQ objects to this request for admission to the extent it requires DEQ to characterize the CHIA, a document which speaks for itself. DEQ admits without waiving this objection.

REQUEST FOR ADMISSION NO. 4:

You are requested to admit that DEQ's CHIA for Amendment AM4 did not address any of the potential hydrologic impacts expected from the proposed Area F operation.

ANSWER: DEQ objects to this request for admission to the extent it requires DEQ to characterize the CHIA, a document which speaks for itself. DEQ admits without waiving this objection.

INTERROGATORY NO. 6:

Please state whether any portion of the proposed Area F operation is within the cumulative hydrologic impact area identified in DEQ's CHIA for Amendment AM4.

ANSWER: A portion of the currently proposed Area F operation is within the cumulative hydrologic impact area identified in DEQ's CHIA for Amendment AM4.

INTERROGATORY NO. 7:

Please state whether any hydrologic impacts from the proposed Area F operation may occur within the cumulative hydrologic impact area identified in DEQ's CHIA for Amendment AM4.

ANSWER: Hydrologic impacts from the proposed Area F operation may occur within the cumulative hydrologic impact area identified in DEQ's CHIA for Amendment AM4.

INTERROGATORY NO. 8:

A. Please state whether any person identified in your answers to INTERROGATORY NO. 1, INTERROGATORY NO. 3 or INTERROGATORY NO. 4 has discussed or considered the propriety of considering potential hydrologic impacts from the proposed Area F operation in DEQ's CHIA for Amendment AM4.

B. Please identify any and all documents in which any person identified above in your answers to INTERROGATORY NO. 1, INTERROGATORY NO. 3 or INTERROGATORY NO. 4 discussed or considered the propriety of considering potential hydrologic impacts from the proposed Area F operation in DEQ's CHIA for Amendment AM4.

ANSWER: (A) Yes, it has been discussed internally by DEQ Coal Program staff. (B) No documents exist.

REQUEST FOR PRODUCTION NO. 1:

Please produce any and all documents in DEQ's possession or control identified in your response to INTERROGATORY NO. 8.

RESPONSE: None exist.

INTERROGATORY NO. 9:

Please identify any applications for mining operations or prospecting work for or related to the proposed Area G operations of the Rosebud Mine that were pending at the time DEQ approved WECo's Amendment AM4 application.

ANSWER: No applications were pending at that time.

INTERROGATORY NO. 10:

Please state whether any proposed operations or prospecting pertaining to Area G are within the cumulative hydrologic impact area identified in DEQ's CHIA for Amendment AM4.

ANSWER: Prospecting has occurred within the CIA. No mining operations were proposed when the CHIA was issued.

INTERROGATORY NO. 11:

Please identify any and all documents in which any person identified above in your answers to INTERROGATORY NO. 1, INTERROGATORY NO. 3 or INTERROGATORY NO. 4 discussed or considered the propriety of considering potential hydrologic impacts from the proposed Area G operations in DEQ's CHIA for Amendment AM4.

ANSWER: There are none.

REQUEST FOR PRODUCTION NO. 2:

Please produce all documents in DEQ's possession or control that are identified in your answer to INTERROGATORY NO. 11.

ANSWER: None exist.

REQUEST FOR ADMISSION NO. 5:

You are requested to admit that DEQ's CHIA for Amendment AM4 defined "anticipated mining" to include "permitted operations."

ANSWER: DEQ objects to this request for admission to the extent it requires DEQ to characterize the CHIA, a document which speaks for itself. DEQ admits without waiving this objection that page 5-1 of the CHIA states: "'Anticipated mining' includes the entire projected life through bond release of all permitted operations and all operations required to meet diligent development requirements for leased federal coal for which there is actual mine-development information available."

REQUEST FOR ADMISSION NO. 6:

You are requested to admit that DEQ's CHIA for Amendment AM4 did not expressly define "anticipated mining" to include "operations with pending applications."

ANSWER: DEQ objects to this request for admission to the extent it requires DEQ to characterize the CHIA, a document which speaks for itself. DEQ admits without waiving this objection.

INTERROGATORY NO. 12:

Please identify any and all "operations required to meet diligent development requirements for leased federal coal for which there is actual mine-development information available" within the cumulative hydrologic impact area identified in DEQ's CHIA for Amendment AM4.

ANSWER: Within the CIA area, mine Areas A, B, C (currently approved mine plans), and F contain leased federal coal subject to diligent development requirement for which mine-development information is available.

INTERROGATORY NO. 13:

Do you contend that DEQ's failure to include proposed operations or prospecting in Area F or Area G in DEQ's CHIA for Amendment AM4 was justified? If your answer is anything

other than an unqualified, "No," please set for with particularity your basis for such justification.

ANSWER: Yes. The proposed action was determined to have no impacts to mine Area C making it unnecessary to include Area F. Page 9-36 of the CHIA states: "As discussed below, proposed mining in AM4 will remove additional overburden in the east part of Area B but will not affect overburden water levels or water quality in other permit areas of the Rosebud Mine." Page 9-37 of the CHIA states: "Due to its [Area C's] location upgradient, proposed mining in Area B will have no impact on water quality or quantity in Area C overburden." Page 9-42 of the CHIA states: "Due to the direction of groundwater flow, Area B mining, including that proposed in AM4, is not expected to increase drawdown or otherwise impact the Rosebud coal groundwater in or near Area C." Page 9-47 of the CHIA states: "Due to the direction of groundwater flow, Area B mining, including mining proposed in AM4, is not expected to impact Area C interburden." Although impacts from the permitted operation in Area C may interact with potential impacts from Area F, impacts from the proposed operation in Area B AM4 do not interact with any potential impacts from Area F. Thus, no analysis was required. DEQ excluded the prospecting and data collection activities under permits X2004322 and N2006005 in "Area G" from the CHIA analysis for two reasons. First, DEQ is not required to address prospecting impacts in the CHIA. Second, prospecting and data collection have no impact on the hydrologic balance.

REQUEST FOR ADMISSION NO. 7:

You are requested to admit that electrical conductivity (EC) standards from ARM 17.30.670 apply to Rosebud Creek.

ANSWER: Admit that the numeric standards for electrical conductivity (EC) contained in ARM.17.30.670(2)(a) and (3)(a) apply to Rosebud Creek.

REQUEST FOR ADMISSION NO. 8:

You are requested to admit that EC standards from ARM 17.30.670 apply to the following tributaries of Rosebud Creek: Spring Creek, Pony Creek, Cow Creek, South Fork Cow Creek, Emile Coulee, and Lee Coulee.

ANSWER: Admit that the numeric standards for EC contained in ARM 17.30.670(4) apply to the tributaries to Rosebud Creek.

REQUEST FOR ADMISSION NO. 9:

You are requested to admit that a portion of Rosebud Creek is within the cumulative hydrologic impact area identified in the CHIA for Amendment AM4.

ANSWER: Admit.

REQUEST FOR ADMISSION NO. 10:

You are requested to admit that the following tributaries of Rosebud Creek are within the cumulative hydrologic impact area identified in the CHIA for Amendment AM4: Spring Creek, Pony Creek, Cow Creek, South Fork Cow Creek, Emile Coulee, and Lee Coulee.

ANSWER: Admit.

REQUEST FOR ADMISSION NO. 11:

You are requested to admit that DEQ's CHIA for Amendment AM4 did not address whether the cumulative hydrologic impacts of mining and reclamation activities within the cumulative hydrologic impact area would cause violation of EC standards in the following tributaries of Rosebud Creek: Spring Creek, Pony Creek, Cow Creek, South Fork Cow Creek, Emile Coulee, and Lee Coulee.

ANSWER: Deny.

INTERROGATORY NO. 14:

Please state whether WECo (including its agency, representatives, and employees) has expressed concerns or doubts to DEQ personnel about its ability to comply with EC standards from ARM 17.30.670 at any point in the past five years. If your answer is anything other than an unqualified "No," please set forth the following information specifically and in detail:

A. Identify who expressed such concerns or doubts;

B. Identify when and where such concerns or doubts were expressed;

C. Identify any and all documents that contain such concerns or doubts;

D. Identify any and all documents in which DEQ personnel discussed or responded to such concerns or doubts.

ANSWER: Yes

(A) Jesse Noel, former Engineering and Environmental Manager for Western Energy Company

(B) Concerns were expressed in a June 13, 2012, Public Comment letter to Jenny Chambers, former Water Protection Bureau Chief regarding the renewal of MPDES permit No. MT0023965.

(C) June 13, 2012, Public Comment letter from Jesse Noel to Jenny Chambers. (See letter page 12, file name: 061312_Noel_Chambers_Public_Comment.pdf)

(D) September 14, 2012, Final decision letter containing DEQ Response to Comments from Jenny Chambers to Kent Salitros, Vice President and General Manager of Western Energy Company (See Response to Comments, Comment 60 on page 19 of 23; file name 091412_Chambers_Salitros_FinalDecsion.pdf).

REQUEST FOR PRODUCTION NO. 3:

Please produce any and all documents in DEQ's possession or control that are identified in your answer to INTERROGATORY NO. 14.

RESPONSE:

- 061312_Noel_Chambers_Public_Comment.pdf, which is attached as Exhibit 1.
- 091412_Chambers_Salitros_FinalDeicsion.pdf, which is attached as Exhibit 2.

INTERROGATORY NO. 15:

Please state whether any DEQ personnel have raised questions or concerns at any point in the last five years about WECo's ability to comply with the EC standards from ARM 17.30.670. If your answer is anything other than an unqualified "No," please set forth the following information specifically and in detail:

A. Identify who raised such questions or concerns;

B. Identify when and where the questions or concerns were raised;

C. Identify any and all documents in which the questions or concerns were raised.

ANSWER: No.

REQUESTION FOR PRODUCTION NO. 4:

Please produce any and all documents in DEQ's possession or control that are identified in your answer to INTERROGATORY NO. 15.

RESPONSE: None identified.

INTERROGATORY NO. 16:

Please identify all water bodies or segments of water bodies within the cumulative hydrologic impact area that are subject to EC standards from ARM 17.30.670.

ANSWER: The EC standards in ARM 17.30.670(2)(a) and (3)(a) apply to Rosebud Creek. The EC standards in ARM 17.30.670(4) apply to all tributaries and other surface waters in the Rosebud Creek watershed.

INTERROGATORY NO. 17:

Do you contend that the failure of DEQ's CHIA for Amendment AM4 to address the potential for violations of EC standards in the Rosebud Tributaries within the cumulative hydrologic impact area was justified? If your answer is anything other than an unqualified, "No," please set for with particularity your basis for such justification.

ANSWER: DEQ disagrees that the CHIA failed to address the potential for these violations.

REQUEST FOR ADMISSION NO. 12:

You are requested to admit that Rosebud Creek is a Class C-3 water under ARM 17.30.629.

ANSWER: Partially admitted. DEQ admits that Rosebud Creek is classified as a C-3 water but denies that it is so classified by ARM 17.30.629. It is classified C-3 by ARM 17.30.611(1)(c).

REQUEST FOR ADMISSION NO. 13:

You are requested to admit that the following tributaries of Rosebud Creek are Class C-3 waters under ARM 17.30.629: Spring Creek, Pony Creek, Cow Creek, South Fork Cow Creek, Emile Coulee, and Lee Coulee.

ANSWER: Admit that all tributaries to Rosebud Creek are classified as C-3 waters but deny that they are so classified by ARM 17.30.629. They are classified C-3 by ARM 17.30.611(1)(c).

REQUEST FOR ADMISSION NO. 14:

You are requested to admit that Rosebud Creek is subject to the water quality standards provided in ARM 17.30.629.

ANSWER: Admit.

REQUEST FOR ADMISSION NO. 15:

You are requested to admit that Spring Creek, Pony Creek, Cow Creek, South Fork Cow Creek, Emile Coulee, and Lee Coulee are subject to the water quality standards provided in ARM 17.30.629.

ANSWER: Admit that the intermittent reaches of these streams are subject to the standard in ARM 17.30.629. Deny that other reaches of these streams are subject to those standards.

REQUEST FOR ADMISSION NO. 16:

You are requested to admit that East Fork Armells Creek is a Class C-3 water under ARM 17.30.629.

ANSWER: Partially admitted. DEQ admits that East Fork Armells is classified as a C-3 water but denies that it is so classified by ARM 17.30.629. It is classified C-3 by ARM 17.30.611(1)(c).

REQUEST FOR ADMISSION NO. 17.

You are requested to admit that East Fork Armells Creek is subject to the water quality standards provided in ARM 17.30.629.

ANSWER: Partially admitted. Where East Fork Armells Creek is ephemeral, it is not subject to the water quality standards of 17.30.629 (see ARM 17.30.637(4)). Where East Fork Armells Creek is perennial or intermittent, it is subject to the standards in ARM 17.30.629.

REQUEST FOR ADMISSION NO. 18:

You are requested to admit that all Class C-3 waters in the cumulative hydrologic impact area are subject to numeric nutrient standards in DEQ Circular DEQ-12A.

ANSWER: Deny. The numeric nutrient standards in DEQ-12A apply to all wadeable streams. Any C-3 waters in the CIA which meet the definition of a wadeable stream in DEQ-12A are subject to the standards in DEQ-12A. Additionally, ephemeral streams are not subject to the water quality standards of 17.30.620 through 17.30.629 (see ARM 17.30.637(4)). Because the numeric nutrient standards in Circular DEQ-12A are referenced in 17.30.629(2)(h), they do not apply to ephemeral streams.

REQUEST FOR ADMISSION NO. 19.

You are requested to admit that DEQ's CHIA for Amendment AM4 did not address or discuss whether the cumulative hydrologic impacts would cause violations of the nutrient standards in DEQ Circular DEQ-12A.

ANSWER: DEQ objects to this request for admission to the extent it requires DEQ to characterize the CHIA, a document which speaks for itself. DEQ admits without waiving this objection.

REQUEST FOR ADMISSION NO. 20:

You are requested to admit that the nutrient standard for total nitrogen, which includes nitrate + nitrite, from DEQ Circular DEQ-12A that applies to the Class C-3 waters in the cumulative hydrologic impact area is more stringent than the human health standard for nitrate + nitrite in DEQ Circular-7.

ANSWER: DEQ objects to this request for admission to the extent it requires DEQ to characterize the CHIA, a document which speaks for itself. DEQ admits without waiving this objection.

REQUEST FOR ADMISSION NO. 21:

You are requested to admit that pursuant to the review required by section 303(d) of the federal Clean Water Act, 33 U.S.C. § 1313(d), DEQ has determined that the lower segment of East Fork Armells Creek is not meeting applicable water quality standards for aquatic life.

ANSWER: Admit.

REQUEST FOR ADMISSION NO. 22:

You are requested to admit that pursuant to the review required by section 303(d) of the federal Clean Water Act, 33 U.S.C. § 1313(d), DEQ has determined that the lower segment of East Fork Armells Creek is not meeting applicable water quality standards for aquatic life because of, among other things, nitrate + nitrite as nitrogen pollution.

ANSWER: Deny. The 2014 DEQ Water Quality Standards Attainment Record for lower East Fork Armells Creek (MT42K002_110-Colstrip to the mouth) identifies nitrate-nitrite as a cause of impairment of aquatic-life-uses with a low level of confidence. This is not a determination that nitrate +nitrite as nitrogen is a cause.

REQUEST FOR ADMISSION NO. 23:

You are requested to admit that pursuant to the review required by section 303(d) of the federal Clean Water Act, 33 U.S.C. § 1313(d), DEQ has determined that the lower segment of East Fork Armells Creek is not meeting applicable water quality standards for aquatic life because of, among other things, nitrogen pollution.

ANSWER: Deny. The 2014 DEQ Water Quality Standards Attainment Record for lower East Fork Armells Creek (MT42K002_110-Colstrip to the mouth) identifies Nitrogen (Total) as a cause of impairment of aquatic-life-uses with a low level of confidence. This is not a determination that nitrogen is a source.

REQUEST FOR ADMISSION NO. 24:

You are requested to admit that pursuant to the review required by section 303(d) of the federal Clean Water Act, 33 U.S.C. § 1313(d), DEQ has determined that coal mining is one source of the pollution causing the lower segment of East Fork Armells Creek to not meet applicable water quality standards for aquatic life.

ANSWER: Deny. The 2014 DEQ Water Quality Standards Attainment Record for lower East Fork Armells Creek (MT42K002_110-Colstrip to the mouth) identifies coal mining as an unconfirmed source of the pollutants. The 2014 DEQ Water Quality Standards Attainment Record lists the confidence in these causes of impairment to aquatic-life-uses as low. This is not a determination that coal mining is a source of this pollution.

INTERROGATORY NO. 18:

Please identify all waters in the cumulative hydrologic impact area identified in DEQ's CHIA for Amendment AM4 that are subject to the nutrient standards in DEQ Circular DEQ-12A.

ANSWER: Perennial and intermittent streams within the cumulative hydrologic impact area are subject to the nutrient standard in DEQ Circular DEQ-12A. West Fork Armells Creek, Stocker Creek, East Fork Armells Creek, unnamed tributaries of East Fork Armells Creek, Spring Creek, Cow Creek, Hay Coulee, Emile Coulee, Lee Coulee, and Rosebud Creek have intermittent or perennial stretches.

INTERROGATORY NO. 19:

Please state whether the nutrient standard for total nitrogen, which includes nitrate + nitrite, from DEQ Circular DEQ-12A that applies to the Class C-3 waters in the cumulative

hydrologic impact area is more stringent than the human health standard for nitrate + nitrite in DEQ Circular-7.

ANSWER: DEQ objects to this request for admission to the extent it requires DEQ to characterize the CHIA, a document which speaks for itself. DEQ admits without waiving this objection.

INTERROGATORY NO. 20:

Please state whether DEQ personnel have considered, addressed, or raised concerns about whether the nutrient standards for total nitrogen from DEQ Circular DEQ-12A apply to surface waters in the cumulative hydrologic impact area. If your answer is anything other than an unqualified "No," please set forth the following information specifically and in detail:

A. Identify who considered, addressed, or raised concerns about the applicability of these standards;

B. Identify when and where the applicability of these standards was considered, addressed, or concerns about their applicability were raised;

C. Identify any and all documents in which the applicability of these standards was considered, addressed, or concerns about their applicability were raised.

ANSWER: Yes

(A) Melissa Sjolund, technical coordinator/MPDES coordinator, Industrial and Energy Minerals Bureau.

(B) DEQ-12A nutrient standards were considered in the Fact Sheet accompanying Major Modification 2 to MPDES permit No. MT0023965 (file name MT0023965_FS_MOD2.pdf)

(C) See p. 6 of the Fact Sheet accompanying Major Modification 2 to MPDES permit No. MT0023965 (file name MT0023965_FS_MOD2.pdf)

REQUEST FOR PRODUCTION NO. 5:

Please produce any and all documents in DEQ's possession or control that are identified in your answer to INTERROGATORY NO. 20.

RESPONSE: The Fact Sheet is attached as Exhibit 3

REQUEST FOR PRODUCTION NO. 6:

Please produce any and all documents that address, discuss, or consider WECo's compliance with DEQ's Circular DEQ-12A at the Rosebud Mine.

RESPONSE: None exist.

INTERROGATORY NO. 21:

Do you contend that the failure of DEQ's CHIA for Amendment AM4 to consider potential violation of total nitrogen standards from DEQ's Circular DEQ-12A was justified? If your answer is anything other than an unqualified, "No," please set for with particularity your basis for such justification.

ANSWER: Yes. There was not enough data available on Total Nitrogen concentrations in waters in the CIA area to make a reasonable determination of the significance of any impacts. In addition, the proposed mining in AM4 is located over one mile from EFAC and is not expected to contribute a measureable amount of additional nitrogen to EFAC via either groundwater or surface water pathways. Finally, compliance with the nutrient standards is addressed in MPDES MT0023965.

REQUEST FOR ADMISSION NO. 25:

You are requested to admit that the dewatering of an intermittent stream outside the mine permit area but within the cumulative hydrologic impact area identified in DEQ's CHIA for Amendment AM4 to the degree that it becomes ephemeral constitutes material damage.

ANSWER: Admit that this dewatering would constitute material damage if a land use or beneficial use of water were adversely affected and deny if the dewatering would not have this adverse effect.

INTERROGATORY NO. 22:

Please state whether in the last five years any person identified your answers to INTERROGATORY NO. 1, INTERROGATORY NO. 3 or INTERROGATORY NO. 4 has considered, addressed, or discussed the intermittent character of any length in the upper segment of East Fork Armells Creek. If your answer is anything other than an unqualified "No," please set forth the following information specifically and in detail:

A. Identify who considered, addressed, or discussed the intermittent nature of any length of the upper segment of East Fork Armells Creek;

B. Identify when and where the intermittent nature of any length of the upper segment of East Fork Armells Creek was considered, addressed, or discussed;

C. Identify any and all documents in which the intermittent nature of any length of the upper segment of East Fork Armells Creek was considered, addressed, or discussed.

ANSWER: Yes.

(A) Current employees of DEQ: Melissa Sjolund, technical coordinator/MPDES; Martin Van Oort, hydrologist; Peter Schade, hydrologist; Robert Smith, permit coordinator; Chris Yde, supervisor, Coal and Uranium Section; Ed Coleman, Bureau Chief, Industrial and Energy

Minerals Bureau. Former employees of DEQ: Angela McDannel, hydrologist, retired; Emily Hinz, hydrologist, now with Fish, Wildlife, and Parks; Dana David, attorney, current employer is the State of New Mexico.

(B) This was discussed on multiple occasions during development of the AM4 CHIA. Specific times and locations of discussions aren't available.

(C) Email message, Emily Hinz to Angela McDannel, dated August 20, 2015, entitled "Section 15 Writeup;" The Fact Sheet accompanying Major Modification 2 to MPDES permit No. MT0023965 discusses the intermittent nature of a segment of East Fork Armells Creek. The June 2, 2014, deficiency letter and January 2016 MPDES permit modification-related documents. See the Fact Sheet accompanying Major Modification 2 to MPDES permit No. MT0023965 (file name MT0023965_FS_MOD2.pdf). Two reports are cited in the Fact Sheet and are provided (file names Arcadis_2014.pdf and Nicklin_2014.pdf

REQUEST FOR PRODUCTION NO. 7:

Please produce any and all documents in DEQ's possession or control that are identified in your answer to INTERROGATORY NO. 22.

RESPONSE: See Exhibits 4 through 7.

REQUEST FOR ADMISSION NO. 26:

Please admit that there are no historic records that identify or describe the instream dam in Section 15 described in DEQ's CHIA for Amendment AM4 on pages 9-9 and 9-10.

ANSWER: Deny.

INTERROGATORY NO. 23:

If your response to REQUEST FOR ADMISSION NO. 26 is anything other than an unequivocal admission, please identify any and all historic records that identify or describe the

instream dam in Section 15 described in DEQ's CHIA for Amendment AM4 on Pages 9-9 and 9-10.

ANSWER: The instream dam in Section 15 is visible on aerial photos from many years and is shown in the CHIA in Appendix A, Photos 18 and 19. This dam is also depicted on several Annual Mine Report maps for WECo Area C. Schwehr, 1979, also describes this instream dam on page 10, "Station No. 9 is located immediately below a small impoundment on the creek." 2011 aerial imagery (Google Earth) clearly shows the pooling of East Fork Armells Creek behind this dam.

REQUEST FOR ADMISSION NO. 27:

Please admit that there are no historic records that attribute the intermittent nature of East Fork Armells Creek in Section 15 to the accumulation of runoff behind the instream dam in Section 15 described in DEQ's CHIA for Amendment AM4 on pages 9-9 and 9-10.

ANSWER: Admit that DEQ's personnel are not aware of any such records.

INTERROGATORY NO. 24:

If your response to REQUEST FOR ADMISSION NO. 27 is anything other than an unequivocal admission, please identify any and all historic records that attribute the intermittent nature of East Fork Armells Creek in Section 15 to the accumulation of runoff behind the instream dam in Section 15 described in DEQ's CHIA for Amendment AM4 on pages 9-9 and 9-10.

ANSWER: Request for Admission No. 27 was Admitted.

REQUEST FOR PRODUCTION NO. 8.

Please produce any and all documents identified in INTERROGATORY NO. 23 and INTERROGATORY NO. 24.

RESPONSE: Interrogatory 23: Schwehr, 1979 was provided to Petitioner on February 18, 2016. The photographs are attached as Exhibits 8 and 9. The1990 Annual Mine Report map is attached as Exhibit 10. The 1992 Aerial Photo map is attached as Exhibit 11.

Interrogatory 24: None exist.

REQUEST FOR ADMISSION NO. 28:

You are requested to admit that DEQ's CHIA for Amendment AM4 did not affirmatively find that the ephemeral character of East Fork Armells Creek in Section 15 was not the result of cumulative hydrologic impacts from the Rosebud Mine.

ANSWER: DEQ objects to this request for admission to the extent it requires DEQ to characterize the CHIA, a document which speaks for itself. DEQ admits without waiving this objection.

REQUEST FOR ADMISSION NO. 29:

You are requested to admit that DEQ's CHIA for Amendment AM4 did not make a material damage determination with respect to the cumulative hydrologic impact of all mining operations on surface water quantity in East Fork Armells Creek in Section 15.

ANSWER: DEQ objects to this request for admission to the extent it requires DEQ to characterize the CHIA, a document which speaks for itself. DEQ admits without waiving this objection.

REQUEST FOR ADMISSION NO. 30:

You are requested to admit that baseline measurements of ground water in the Rosebud Coal in Area B identified some groundwater that would classify as Class I groundwater under ARM 17.30.1006(2).

ANSWER: DEQ objects to this request for admission to the extent it requires DEQ to characterize the CHIA, a document which speaks for itself. DEQ admits without waiving this objection.

REQUEST FOR ADMISSION NO 31:

You are requested to admit that baseline measurements of ground water in the Rosebud Coal between the Rosebud Mine and the Big Sky Mine identified some groundwater that would classify as Class I groundwater under ARM 17.30.1006(2).

ANSWER: Deny that baseline measurements in Appendix D of the CHIA in Rosebud Coal wells between the Rosebud Mine and Big Sky Mine have groundwater with conductivity which falls in the Class I range, but admit that the CHIA references an EC of 880µS/cm measured in 1996 in a Rosebud coal well north of Big Sky Mine Area A.

INTERROGATORY NO. 25:

Please identify the average and median concentrations of total dissolved solids (TDS) from baseline samples of ground water in the Rosebud Coal in Area B.

ANSWER: Based on the data contained in Appendix D of the CHIA, the average TDS for Rosebud Coal wells in Area B is 1324 mg/L and the median is 1283 mg/L. For this analysis only, wells located with the current Area B permit boundary were used.

INTERROGATORY NO. 26:

Please identify the average and median concentrations of TDS in base line samples of ground water in the Rosebud Coal between the Rosebud Mine and the Big Sky Mine.

ANSWER: Based on the data contained in Appendix D of the CHIA, the average TDS for Rosebud Coal wells between the Big Sky and Rosebud Mines is 1806 mg/L and the median is

1880 mg/L. All wells located between the Rosebud and Big Sky mined areas were included in this analysis, regardless of their position inside or outside the mines' permit boundaries.

REQUEST FOR ADMISSION NO. 32:

You are requested to admit some of the spoil water from Area B of the Rosebud Mine is expected to migrate to the southeast toward unmined portions of the Rosebud Coal between the Rosebud Mine and the Big Sky Mine.

ANSWER: Admit.

REQUEST FOR ADMISSION NO. 33:

You are requested to admit that the spoil water from Area B of the Rosebud Mine that is expected to migrate to the southeast toward unmined portions of the Rosebud Coal between the Rosebud Mine and the Big Sky Mine is expected to have TDS concentrations that would classify as Class II or Class III ground water under ARM 17.30.1006.

ANSWER: Deny. TDS concentrations are not used to classify groundwater under ARM 17.30.1006. The groundwater classes in ARM 17.30.1006 are defined by natural specific conductance. Admit that the that the spoil water from Area B of the Rosebud Mine that is expected to migrate to the southeast toward unmined portions of the Rosebud Coal between the Rosebud Mine and the Big Sky Mine is expected to have specific conductance concentrations that would classify as Class II or Class III ground water under ARM 17.30.1006.

REQUEST FOR ADMISSION NO. 34:

You are requested to admit that degradation of Class I ground water in the Rosebud Coal outside the mine permit boundary to Class II or Class III ground water would be a violation of water quality standards.

ANSWER: Admit it would be a violation if the specific water quality standards listed for Class I groundwater were violated, but deny that it would be a violation in other instances.

REQUEST FOR ADMISSION NO. 35:

You are requested to admit that the DEQ's CHIA for Amendment AM4 does not address the potential degradation of Class I ground water in the Rosebud Coal between the Rosebud Mine and the Big Sky Mine.

ANSWER: DEQ objects to this request for admission to the extent it requires DEQ to characterize the CHIA, a document which speaks for itself. DEQ asserts without waiving this objection that DEQ's CHIA did not address potential degradation of Class I groundwater in the Rosebud Coal between the Big Sky and Rosebud mines because there is no Class I groundwater in that area.

REQUEST FOR ADMISSION NO. 36:

You are requested to admit that the CHIA does not identify any hydraulic connection between clinker deposits between the Rosebud Mine and the Big Sky Mine and the Rosebud Coal between the Rosebud Mine and the Big Sky Mine.

ANSWER: DEQ objects to this request for admission to the extent it requires DEQ to characterize the CHIA, a document which speaks for itself. DEQ denies without waiving this objection.

REQUEST FOR ADMISSION 37:

You are requested to admit that that Clark, 1995, submitted as Exhibit 3 in public comments submitted by Petitioners MEIC and Sierra Club, found that TDS concentrations were either unchanged or changed only in small amounts as ground water flowed from the Big Sky Mine spoils aquifer to the downgradient coal aquifer.

ANSWER: Admit.

INTERROGATORY NO. 27:

Please identify any and all documents in which DEQ personnel identified in INTERROGATORY NO. 1, INTERROGATORY NO. 3, and INTERROGATORY NO. 4 discuss or address potential impacts of migration of spoils water from Area B of the Rosebud Mine.

ANSWER: None exist.

REQUEST FOR PRODUCTION NO. 9:

Please produce any and all documents identified in INTERROGATORY NO. 24.

RESPONSE: None exist.

REQUEST FOR ADMISSION NO. 38:

You are requested to admit that in 2014 DEQ personnel had concerns about material damage occurring off the Rosebud Mine site that may have been related to the Rosebud Mine.

ANSWER: Admit.

INTERROGATORY NO. 28:

Please state whether any DEQ personnel has raised concerns about material damage occurring off the Rosebud Mine site that may have been related to the Rosebud Mine. If your answer is anything other than an unqualified "No," please set forth the following information specifically and in detail:

A. Identify who raised such concerns;

B. Identify what concerns were raised, including what pollutants or impacts to water quantity were involved;

C. Identify any and all documents in DEQ's possession or control in which such concerns were raised, considered, or discussed.

ANSWER: Yes.

(A) Former employees of DEQ's Industrial and Energy Minerals Bureau: Emily Hinz, hydrologist, now with the Department of Fish, Wildlife, and Parks; and Angela McDannel, hydrologist, retired.

(B) Concerns were raised that potential inputs of additional salinity, sulfate, and chloride to East Fork Armells Creek from the Rosebud Mine may cause material damage to the protected beneficial use aquatic life support for C-3 waters.

(C) See "AM4 Seventh Round Acceptability Deficiency.pdf"

REQUEST FOR PRODUCTION NO. 10:

Please produce any and all documents in DEQ's possession or control that you identified in your response to INTERROGATORY NO. 27.

RESPONSE: None exist.

INTERROGATORY NO. 29:

Please state in detail and with specificity any and all concerns that DEQ personnel have raised about material damage occurring off the Rosebud Mine site that may have been related to the Rosebud Mine.

ANSWER: See answer to Interrogatory No. 28. B.

INTERROGATORY NO. 30:

Please identify any and all documents in DEQ's possession or control in which any individual identified in INTERROGATORY NO. 1, INTERROGATORY NO. 3, or INTERROGATORY NO. 3 discusses the impairment of East Fork Armells Creek, as determined

in DEQ's review required by section 303(d) of the federal Clean Water Act, 33 U.S.C. § 1313(d).

ANSWER: September 8, 2014, Final decision letter containing DEQ Response to Comments from Jon Kenning, Water Protection Bureau Chief, to Kent Salitros, vice president and general manager of Western Energy Company (See Response to Comments, Response 9, page 9; file name 090814_Kenning_Salitros_FinalDeicsion.pdf).

The Fact Sheet accompanying the 2012 renewal of MPDES permit No. MT0023965 (see p. 20 of 73, file name MT0023965_FS_Renewal.pdf). September 14, 2012, Final decision letter containing DEQ Response to Comments from Jenny Chambers to Kent Salitros, Vice President and General Manager of Western Energy Company (See Response 19 on page 8 of 23; file name 091412_Chambers_Salitros_FinalDeicsion.pdf).

REQUEST FOR PRODUCTION NO. 11:

Please produce any and all documents identified in your answer to INTERROGATORY NO. 30.

RESPONSE:

- 090814_Kenning_Salitros_FinalDeicsion.pdf is attached as Exhibit 12.
- MT0023965_FS_Renewal.pdf is attached as Exhibit 13.
- 091412_Chambers_Salitros_FinalDeicsion.pdf is attached as Exhibit 14.

REQUEST FOR ADMISSION NO. 39:

You are requested to admit that Sigler and Bauder, 2012, cited in DEQ's CHIA for Amendment AM4 on page 2-4 is not a peer-reviewed study.

ANSWER: Admit.

REQUEST FOR ADMISSION NO. 40:

You are requested to admit that Hutcheson, 2001, cited in DEQ's CHIA for Amendment AM4 on page 2-4 is not a peer-reviewed study.

ANSWER: Admit.

REQUEST FOR ADMISSION NO. 41:

You are requested to admit that Geomega, 2007, cited DEQ's CHIA for Amendment AM4 on page 6-2 is not a peer-reviewed study.

ANSWER: Admit.

REQUEST FOR ADMISSION NO. 42:

You are requested to admit that Raisbeck et al., which was submitted as Exhibit 4 of Petitioner's comments is a peer-reviewed study.

ANSWER: Deny.

REQUEST FOR ADMISSION NO. 43:

You are requested to admit that the chronic exposure limit for sulfate recommended in Raisbeck et al., is lower than the sulfate limits from Sigler and Bauder, 2012, Hutcheson, 2001, or Geomega, 2007.

ANSWER: Admit that Raisbeck is lower than Sigler and Bauder and Geomega, but deny that Raisbeck is lower than Hutcheson.

INTERROGATORY NO. 31:

Please identify all cumulative hydrologic impact assessments prepared by DEQ for any mining operation at the Rosebud Mine or the Big Sky Mine. Please also identify the particular operation or mining area for which each cumulative hydrologic impact assessment was prepared.

ANSWER: Cumulative Hydrologic Impact Assessments were conducted for the following applications: Big Sky Mine Area A Snider's Amendment, April 1987; Big Sky Mine Area B,

New Permit, November 1988; Big Sky Mine Area B Application 180, June 2007; Rosebud Area C Application 172, August 2006; Rosebud Mine Area D Application 115, November 1985; Rosebud Mine Area C Application 125, January 1989; Rosebud Area D Application 161, October 2001; Rosebud Area Mine B Application 134, January 1995; Rosebud Mine Area B Second Extension, June 1983; and Rosebud Mine Area A Application 107, June 1984.

REQUEST FOR PRODUCTION NO. 12:

Please produce all of the following documents:

A. Schwehr, 1981 (cited in DEQ's CHIA for Amendment AM4 at 9-9);

B. WECo, 1986 (cited in DEQ's CHIA for Amendment AM4 at 9-9);

C. MME, 1995 (cited DEQ's CHIA for Amendment AM4 at 9-9);

FORWARD

This final environmental impact statement is submitted pursuant to the Montana Environmental Policy Act, (MEPA), Section 69-6504 (b)(3). The statement was prepared by the Environmental Sciences Division of the Montana State Department of Health and Environmental Sciences, regarding a coal-fired electric generating plant proposed for construction near Colstrip, Montana, for which an application has been received for a permit to construct.

Although MEPA requires this agency to assess all forseeable impacts that might result from construction of the proposed plant, issuance of the requested permit is contingent only upon adequate demonstration by the applicant of the ability to prevent illegal air pollution. To date, research by the State and the applicant has not indicated that illegal air pollution would result.

Under MEPA, agencies and individuals have 30 days to comment following publication of a final environmental impact statement. If, within that time, no credible evidence of illegal pollution is received, the permit will be issued as requested.

Comments should be submitted to the Air Quality Bureau, Montana State Department of Health and Environmental Sciences, Cogswell Building, Helena, Montana, by April 20, 1973.

Exhibit 4

Exhibit 4

SUMMARY: FINAL ENVIRONMENTAL IMPACT STATEMENT

Coal-Fired Steam Electric Plant, Colstrip, Montana
Prepared by Montana State Department of Health and Environmental Sciences
Environmental Sciences Division

1. TYPE OF ACTION: Administrative

2. DESCRIPTION OF ACTION:

The Montana Power Company and the Puget Sound Power and Light Company have made application for a Construction Permit to the Montana State Department of Health and Environmental Sciences, Environmental Sciences Division, for a 700-megawatt coal-fired steam electric power generating plant to be located just east of Colstrip, Montana. The first unit is scheduled for completion in 1975 and the second in 1976. The Montana Environmental Policy Act required that an impact statement be submitted and evaluated prior to any major action, in this case the granting of a Permit to Construct.

The generating station will burn coal from an adjacent mine. The coal will be transported by truck from the mine to a crusher and from there to the plant by conveyer. Cooling water, boiler make-up water, and scrubber water will be transported by pipeline from the Yellowstone River, about 31 miles to the North. There will be no return to the river.

The companies propose to construct two additional transmission lines from Colstrip to the Billings area.

3. PROBABLE IMPACT OF THE PROPOSED ACTION ON THE ENVIRONMENT

Sulfur oxides, particulate, nitrogen oxides, trace elements, water vapor and heat will exhaust from two 500-foot stacks. Emission and ambient air levels probably will comply with all state and federal standards. Effects of pollutants, including fluorides, on flora and fauna, weather, and aesthetics appear minimal, although subtle long-term effects may be indeterminable.

Construction of the power plant, cooling systems, transmission lines, pipeline, and strip mine development impose primary and secondary impacts on the environment. These will affect flora and fauna, aesthetics, the economy, society and others.

4. PROBABLE ADVERSE ENVIRONMENTAL EFFECTS WHICH CANNOT BE AVOIDED, SHOULD THE PROPOSAL BE IMPLEMENTED

Some of the adverse effects include the consumption of a non-renewable resource, air quality degradation, disturbance of land by mining, and aesthetic degradation.

5. ALTERNATIVES TO THE PROPOSED ACTION

The only alternative feasible within the time frame set for construction of the plants is a reduction in the rate of increase of the use of electrical energy.

6. SHORT TERM BENEFITS VS. LONG TERM EFFECTS

The long-term adverse effects may well outweigh the short term gains.

Exhibit 4

Exhibit 4

7. IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS OF NATURAL RESOURCES

The proposed plant will consume 90 million tons of coal over the 30-year life of the plant, or three million tons per year of this non-renewable resource.

8. RESPONSE TO THE DRAFT STATEMENT

Over 3000 responses have been received commenting directly or indirectly on the draft statement, mostly in opposition to the construction.

Exhibit 4

SUMMARY OF STATISTICS OF COLSTRIP PLANT

Location	One mile east of Colstrip, Montana, 30 miles south of I-94, at Forsyth; Section 34, Township 2 North, Range 41 East, Rosebud County, Montana
Elevation	3200 feet above sea level
Ownership	The Montana Power Company and Puget Sound Power and Light Company
Operation	Montana Power Company
Scheduled Completion	Unit #1, July, 1975; Unit #2, July, 1976
Total Cost	$183,000,000
Steam Generator	Combustion Engineering Company
Capacity	2,520,000 lb steam/hr/unit
Size	206 feet high, 160 feet wide, 238 feet long
Turbines	General Electric
Capacity	350 mw/unit, 700 mw total (nominal)
Cooling Towers	Ecodyne Corporation Wet crossflow induced draft type 65 feet high, 48 feet wide, 252 feet long; 117,200 gal/min inlet water/unit
Stack	Two stacks--each 500 feet high, approximately 30 feet diameter at base
Scrubbers	
Type	Venturi with alkali chemical system
Capacity	1,600,000 cu. ft. per min. @ 293°F
Buildings	300 feet high, 160 feet wide, 238 feet long
Coal	385,000 #/hr; 8,843 BTU/#, 23.87% moisture, 0.77% sulfur, 8.59% ash
Mine	Strip-type, approximately 65 surface acres/year, 3,000,000 tons of coal/year
Transmission Lines	3 lines, 230 kv each, 60 feet high, 800 feet average span, 3 conductors, 2 shield wires per line
Pipeline	22" to 26" diameter, (minimum), approximately 30 miles
Water Consumption	8,000 gals per minute, 4.2×10^9 gal per year
Settling Ponds	30 surface acres, 100 acre feet

Exhibit 4

Exhibit 4

I. DESCRIPTION OF PROPOSED ACTION

Exhibit 4

Exhibit 4

I. DESCRIPTION OF PROPOSED ACTION

Plant and Process

The Montana Power Company (MPC) and the Puget Sound Power and Light Company propose to construct a 700 megawatt electrical generating station near Colstrip, Montana. This complex of two 350 mw units would provide electricity for Montana users and for delivery to the Northwest Power Pool, of which the two companies are members. The plant would burn coal, supplied from deposits in the immediate area of Colstrip. The first unit is scheduled for completion by July, 1975, and the second by July, 1976.

The proposed plant would be the third coal-fired steam electric generating facility and the first "mine-mouth" plant to be constructed in Montana. Montana Dakota Utilities' 44 mw plant at Sidney (1958) and Montana Power's 180 mw Corette plant at Billings (1968) are small by comparison. The applicant (MPC) states that economic, technical and environmental considerations favor locating the plant at Colstrip rather than nearer the load centers. Mine-mouth generation is not always favored, as demonstrated by the large amount of Montana low sulfur coal now being contracted to power plants old and new in the midwest.

In the case of the proposed Colstrip plant, the applicant states that the mine-mouth facility is favored in part because no new transmission lines will be required west of Billings. One line currently is under construction to carry electricity from Billings to the plant until generation begins. The power flow would then be reversed, with electricity produced at Colstrip flowing to Billings.

Two additional lines are in the planning stage. No routes have been selected, the applicant states, although corridors have been selected, as illustrated in the section on impacts.

The alternative of hauling coal to a plant nearer the load centers would leave the applicant open to disruptions from labor disputes, increased costs from increasing railroad rates, and other continuing costs. By contrast, a power line, once built, has relatively little maintenance cost.

Exhibit 4

Environmentally, the Colstrip area was favored for the project because it

> "is remote and the development would affect few people directly . . ."

according to the applicant. Further, the applicant asserts,

> "the weather patterns of eastern Montana are generally less confining than the more mountainous terrain of much of MPC's service area."

Continuing in the words of the applicant:

> "Existing land use levels would be upgraded by the proposed development; i.e., more people would realize more use from the energy available from this land than the values being received by very few people at its present level of use. Also, the land disturbed by the mining activity will be reclaimed, and the extensive research over the past 5 years in WECo's (Western Energy Company) area, indicates the disturbed land will be back in production in 3 to 5 years. The site adjacent to the town of Colstrip minimizes the travel and time of the operating personnel to and from work, as town facilities, including homes, would be provided by expanding the existing village."

A number of other possible sites within the MPC service area were investigated before Colstrip was selected. MPC data indicate two of the sites considered were Cushman, near Ryegate, and Springdale, between Livingston and Big Timber. Economic evaluation found Colstrip was favored on a cost basis by less than one percent. Nevertheless, Colstrip was chosen, for reasons previously mentioned.

Air pollution probably is the most serious environmental effect of coal-fired generating plants. Potential air pollution from the proposed plants would be controlled by venturi wet scrubbers. The scrubbers purchased for the Colstrip plant are designed to remove both SO_2 and particulate matter from the combustion gases. Although venturi scrubbers of various design have long demonstrated a high efficiency in removal of particulate matter larger than 2 micron, their long-term reliability for SO_2 removal still is questioned by the utility industry.

The EPA is convinced that wet scrubbers using lime slurry can effectively control SO_2, and the EPA New Source Performance Standards were formulated on the assumption of their workability.

In justifying its new source standards, the EPA stated as follows:

> "The administrator took into account the following facts in determining that there has been adequate demonstration of the achievability of the standard.

Exhibit 4

"There are at present three SO_2 removal systems in operation at U. S. power stations. Moreover, a total of thirteen electric power companies have contracted for the construction of seventeen additional units, most of which will become operational in the next two years."

The EPA then mentioned three units which have had adequate success in operation. The most successful of the three was a Bahco unit which had no serious operational difficulties between November, 1969, and March 21, 1972, when the EPA justified its standard in the Federal Register.

A number of venturi scrubbers have demonstrated effective removal of SO_2 over a relatively short trial period, but the degree of their efficiency over longer periods is in the test stage.

An article in the December, 1972, Engineering and Mining Journal assessed the state of the art of SO_2 removal as follows:

"It has been independently concluded by a number of investigators that the wet limestone scrubbing process is the closest to commercial availability of the many processes suggested to date. Under pressure from regulatory bodies, commitments have been made by the utilities industry to build large, commercial-prototype installations employing limestone scrubbing. However, despite extensive laboratory and pilot plant research to date, a more realistic view is that considerable development work remains to be done before the process can be considered 'proved.'"

Continuing, "A difficult and perhaps extended period of shakedown can be anticipated for the initial commercial units now being built or started up in the utility industry. And although these units are being installed in commercial systems, they must be regarded as development in nature."

A recent technical conference on the subject revealed a wide range of problems being experienced by operators of venturi scrubbers on power plants.[10] At the conclusion of the conference, the program chairman addressed the assembly as follows:

"Let me say that a lot of what you've heard today sounds pessimistic. You really wonder how these companies stand all of the pains they're going through. But thank God for those who are paying the price to lead us into this important technology.

"There were a lot of pessimistic reports on many of the pioneering nuclear plants in days past. There were continual embarrassments and cost and schedules were often way out. But go back and see how well those plants are running today and compare their capital costs with today's estimates. Those pioneers paid a price to lead us into nuclear technology, but in the end, many got a bargain."

Exhibit 4

"I had a couple of people tell me last night that they're scrambling now to get up to speed on sulfur-removal technology, and that they wish they already had a couple of years' experience in running a scrubber. So I hope there's some analogy here to the early nuclear experience. Gentlemen, I thank you. I'm sure the whole industry thanks you for leading the way."

Recent experience elsewhere indicates venturi scrubbers can be operated reliably and efficiently on large power plants. At the Dave Johnston plant near Casper, Wyoming, for example, gasses from a 320 MW unit have been scrubbed at an efficiency above 99 percent on particulate and about 50 percent on SO_2.[33]

Although the plant does not fall under the EPA New Source Performance Standards, the owner, Pacific Power and Light, intends to spend $30 million installing scrubbers on the other three stacks at the Casper plant, believing them to be more effective in pollution control than electrostatic precipitators.

The scrubbers for the proposed Colstrip plant would be substantially over-designed and operated in parallel with three venturis on each unit. Should one venturi malfunction or require maintenance, the boiler still could operate at 80 percent of full load, with the two operating venturis maintaining the design collection efficiency.

All assumptions made by the State regarding the potential for air pollution are contingent upon operation of the scrubbers at the efficiencies guaranteed to the applicant by the supplier; 99.5 percent on particulate, 39.7 percent SO_2 removal. Performance at these efficiencies would limit SO_2 emissions to 1.0 lb SO_2/million BTU, and fly ash emission to .018 grains per actual cubic foot, at any operational load.

Should the scrubbers malfunction, the operating load of the plant would have to be reduced to whatever load could be handled by the remaining operable scrubbers. There is no bypass for combustion gas to escape around the scrubbers, and the plant will not be allowed to operate in violation of state and federal air pollution laws. Monitoring of ambient air and stack gasses will be performed as the need is seen.

The applicant will follow the requirements of the Environmental Protection Agency by installing in-stack continuous monitoring equipment for particulates, sulfur oxide, and nitrogen oxides. Test ports will be placed in the stack and breaching for source monitoring by the company and state and federal agencies.

Exhibit 4

The state is confident that the system ordered by the applicant for pollution control is as effective as any on the market today.

A study of venturi scrubbers on power plants performed for the EPA indicated a high efficiency on a variety of pollutants generated in coal combustion. Hydrogen fluoride, one of the most worrisome pollutants, was removed, along with other soluble gasses, at an efficiency averaging 90 percent. The lowest removal efficiency of the gasses was 70 percent, the highest 99.7.

Tests at a pilot venturi scrubber operating at the J. E. Corette plant in Billings indicated an average fluoride removal above 90 percent. More specific data is included in the section on Emissions. A description of the scrubber operation follows later in this section.

Mechanical draft evaporative cooling towers will be used to cool the plant. There will be no discharge of heated water, except into the air as vapor.

The towers would be

> "supplied by Ecodyne Cooling Products Company. The size and location have been shown in the construction permit application. Each plant unit will have one cooling tower of seven cells. The fans will be powered by 200 hp motors and will use 185.2 hp at rating. The towers are rated at an inlet wet bulb temperature of 60°F and will have a range of 31.7°F and an approach of 21.5°F when cooling 113,000 gpm of 113.2°F water. Actual condenser flow will be 104,000 gpm. Evaporative loss at rating will be 3.17% and guaranteed maximum drift will be 0.02%. Under these conditions, the water consumed by the towers will be 3,323 gpm at the required condenser flow."

The cooling towers will receive hot water from the plant condensers and return cool water to condense steam from the turbines. Blowdown from both the cooling towers and the boiler will be discharged to the ash pond. Pond water will be recirculated to the scrubbers in a closed loop system. Collected flyash from the scrubbers, bottom ash from the boilers, and economizer ash will be sluiced to the ash pond, and periodically removed for disposal in a manner not yet determined. Two ash ponds designed for decanting and draining would aid in the ash disposal. The ponds will be sealed with bentonite or plastic to prevent leaching.

Exhibit 4

Pipeline and Water Supply

Plant water will be obtained from the Yellowstone River and supplied to the plant by a buried steel pipeline at least 22 inches in diameter. The pipeline will intercept the Yellowstone at one of three possible points illustrated in Fig. 1. It will carry 8,000 gallons of water per minute to a 100 acre-feet surge pond. The pond, covering approximately 30 surface acres, will hold a three-day supply of water for the plant.

Transmission Lines

As previously noted, electricity would be transferred by three 230 KV transmission lines, originating in the plant switchyard and extending west to the Billings area. The line now under construction is routed south of the Yellowstone River Valley through Hardin to the J. E. Corette steam electric generating station in Billings. Two additional lines are scheduled for completion in mid-1975 and 1976. These two lines will share a common corridor where feasible, crossing the Yellowstone River Valley east of Billings at a location yet to be determined. They will terminate at a new substation to be added to the Montana Power Company's integrated system north of Billings. Each line will consist of three conductors and two shield wires supported by two vertical wooden poles with some three pole structures where required. The lines will be approximately 60 feet high with an average of 800 feet between poles.

The Billings substation will be the termination point of six 230 KV lines. Two of these, one from Anaconda and one from the Corette plant, are already operating. An additional line from the Billings plant would be put on the existing double circuit towers. Another of these lines will be the Billings-Great Falls line, construction of which will begin in 1973. The Colstrip lines would be the last two lines to terminate in the substation. No surveying has begun on the two Colstrip lines, according to the applicant. No right-of-way was procured as of January 31, 1973. In the words of the applicant,

> "A July, 1973, completion of preliminary survey is necessary to allow sufficient time to evaluate environmental engineering, right-of-way, and material

Exhibit 4

considerations before construction which must commence in the spring of 1974."

Power lines and pipelines are further noted in the section on Impacts.

Strip Mining and Coal Supply

Western Energy Corporation, a wholly owned subsidiary of Montana Power Company, will supply coal for the generating facility. Approximately 65 surface acres will be mined each year to supply the estimated consumption of three million tons of coal per year. Coal will be trucked from the mine pits to a crusher and taken by conveyor belt to the plant site stockpile. The Montana State Department of Lands will make intensive evaluations of the strip mining and reclamation necessary for this facility. Environmental impact statements will be written, as required by the Montana Environmental Policy Act of 1971. The Department of Lands also requires that permit applications be submitted and the mining will be closely regulated.

The vast quantities of strippable coal in eastern Montana and the Fort Union Region suggest further electrical energy development in the area. The North Central Power Study, funded and supported by the Bureau of Reclamation in collaboration with some 35 interested utilities, proposed development of up to 53,000 mw generating capacity in the Fort Union Region of southeastern Montana and northern Wyoming. The Montana Power Company and Puget Sound Power and Light Company are considering at least two additional 700 mw units at Colstrip.

Construction and Location

The proposed plant will be located immediately east of the company town of Colstrip, about 30 miles south of Interstate 94 at Forsyth and about 90 cross-country miles due east of Billings. Montana Power Company owns and has available 1365 acres for the plant site. This area will contain the two thermal electric generators, cooling towers, surge pond, ash ponds, and a coal storage area.

Employment during construction will peak at 800-900 men. Following construction, approximately 44 persons will be required to operate Unit #1, and 19 more will be

Exhibit 4

required for Unit #2. An additional 55 employees will be needed in the mining operation. Operating personnel and mining employees probably will be housed in Colstrip. The Ken R. White Company of Denver, land-use planners and designers, has developed a town plan.

The total cost of the proposed facility will be in excess of $183 million. The Bechtel Corporation, headquartered in San Francisco, is the engineer-contractor for the generating facility.

Detailed Description of Process

Figure 2 illustrates a material balance for the generating facility as submitted by the applicant.

Following is a more detailed process description1 also submitted by the applicant:

"Coal of approximately 1.5 inch lump size is transported to the plant storage site. It is mechanically conveyed into the plant and fed to coal pulverizers which reduce it in size from 1.5 inches to a size such that 70% of the coal will pass through a 200 mesh sieve. The pulverized coal is then used as combustion fuel for a steam generator. The coal is fed into the steam generator through fuel nozzles, which are located at the four corners of a furnace. The coal is mixed with air in the furnace and ignited. The combustion process gives off energy in the form of heat which is transferred through the furnace walls to water which is converted to steam at 2,400 lbs per sq. inch and 1,000°F. The steam is piped to a turbine which extracts energy by reducing the steam to a low pressure and temperature. The energy is used to rotate the shaft of an electric generator whose output is delivered to an electric transmission system exterior to the plant.

"The low pressure steam exhausted from the turbine is reconverted to water by cooling in a condenser, and then returned to the steam generator for reuse. The cooling is accomplished by supplying water at a lower temperature than the steam to the tube side of a shell and tube heat exchanger (condenser). The cooling water absorbs the heat of the condensing steam through the tube walls and is pumped to a cooling tower where it is exposed in the form of droplets to a flow of atmospheric air. The air evaporates some of the water causing the balance to be cooled so that it can be returned to the condenser for reuse. Fresh water to replace the amount that is evaporated is supplied to the cooling tower from the surge pond or pipeline.

"In the steam generator, the unused portions of the combustion air and the gaseous products of combustion are combined, and along with any suspended fly ash from the burned coal, are conveyed to a flue gas scrubbing system installed for emission control. This is a full stream scrubber system that will simultaneously remove fly ash and sulfur dioxide. The removal is accomplished by scrubbing the flue gas with an alkaline solution of water

Exhibit 4

Exhibit 4

Figure 2

and calcium carbonate, which is generally available from the fly ash. If the alkalinity of the ash varies to a point where additional alkalinity must be added, it is obtained by the addition of soda ash (Na_2CO_3) or lime (CaO). The gaseous sulfur dioxide will react with the calcium carbonate to form solid calcium or sodium salts. At the same time, the mechanical action of the scrubber traps fly ash particles in the water droplets. Recirculation within the scrubber system makes the alkalinity in the ash available for the process. The used scrubber solution, newly formed salts, and trapped fly ash are piped to an ash pond where the solids settle out. The pond water is then recirculated back to the scrubber in a closed loop system from which no water is discharged to any natural bodies. This emission control system is guaranteed to limit the sulfur oxide emissions to 1.0 lb SO_2/million BTU and the fly ash emissions to .018 grains per actual cubic foot, at any operational load of the power plant.

"The coal charged into the process will have the following average composition:

Moisture	23.87%
Fixed Carbon	38.95
Volatile Matter	28.59
Ash	8.59
	100.00%
Sulfur	0.77% (included above)
Heating Value	8,843 BTU/lb

At full load, 385,500 lbs per hour of this fuel will be burned in each unit corresponding to 3,410 million BTU per hour of heat release per unit. The corresponding sulfur oxide production would be 5,650 lbs per hour SO_2 or 1,658 lbs SO_2 per million BTU input. The flyash production would be 26,492 lbs per hour, since 20% of the total input of 33,114 lbs per hour will become attached to the furnace walls and removed as boiler slag while the balance leaves the furnace as fly ash. This corresponds to 7.77 lbs of fly ash per million BTU.

"The guarantees on the emission control systems are equivalent to 99.5% particulate removal and 39.7% SO_2 removal, which will limit particulate emissions to 0.039 lbs per million BTU input and sulfur oxide emissions to 1.0 lbs per million BTU input."

Detailed information on the scrubber system follows:

"The supplier of the system will be Combustion Equipment Associates, Inc., 555 Madison Avenue, New York, New York, 10022. The pollution control system consists of three venturi scrubber trains to handle flue gases from each 361.8 mw (gross) generating units. Each venturi scrubber train consists of a venturi scrubber, reheater, I.D. fan, and associated ductwork and piping. The bleed from three scrubber trains is combined and pumped to an ash pond. Each venturi scrubber provides two contacts between liquor and gas streams for optimum removal of both fly ash and SO_2. The first contact in the venturi throat section is of co-current flow type (both liquor and gas flowing in the same direction) whereas the second contact is counter-current flow type (liquor and gas flowing in the opposite direction) and occurs in the separator section--just below the mist eliminators where the flue gas is exposed to

sprayed liquor. Essentially all the fly ash removal is attained in the throat section with partial removal of SO_2, and the counter-current spray sections are used to optimize SO_2 removal.

"A portion of the total flue gas containing fly ash and sulfur oxides enters each venturi scrubber, where it is contacted with recycle liquor for fly ash and sulfur oxides removal. The accelerating flue gas shatters the curtain of liquor in the throat into small droplets. These droplets not only trap the dust particles but also provide mass transfer surface for absorption reagent.

"The flue gas and liquor flow downward through the down-comer section. The liquor settles by gravity into the integral recycle tank, whereas the flue gas turns 180 degrees for further contact with the recycle liquor in the counter-current spray zone.

"Each venturi scrubber is provided with recycle pumps (3 - 60% capacity, two operating and one spare) and piping. The bleed from the scrubber is taken from the discharge side of the recycle pumps, and after combining with the bleed from other scrubbers, is sent to the ash pond for final settling. The clear overflow from the ash pond is returned to the scrubber system. The makeup water, equivalent to evaporation plus liquor remaining with the ash pond cake, is added to the scrubber. The makeup water is to be supplied from the plant cooling towers blowdown (CTBD). Part of the CTBD makeup water, treated to the extent of reducing the dissolved solids of Ca ppm as $CaCO_3$ to the river water level, is utilized in the form of sprays to clean any buildup occurring on the mist eliminators.

"The system is designed to use the alkali content of the fly ash for SO_2 removal.

"The materials of construction for all pumps and piping are rubber lined and the system is designed with utmost care to minimize scaling, buildup, erosion and corrosion problems. Using the fly ash as the source of alkali for the process will require a slurry concentration of 6 to 12% in the recycle loop, and this condition will help minimize scaling problems by providing an abundant source of seed crystals for scale to form on.

"The cleaned flue gas then enters the chevron-type mist eliminator where any entrained liquor droplets are efficiently separated and collected from the flue gas. A spray washing system--both above and below the mist eliminator--is provided to prevent any significant buildup on the eliminator section. The entrainment free flue gas is reheated in a steam coil type reheater before entering an induced draft fan. Three sets of plate coil type indirect steam reheaters are provided for reheating the scrubber flue gas by a maximum of 50°F. Soot blowers are included to clean out any possible buildup on the heat exchange surfaces. The dry I.D. fans, one for each scrubber train, handle flue gases leaving the reheaters. The flue gas is combined with the flow from the other scrubber trains and discharged to the atmosphere through a stack.

"The attached scrubber process flow sheet illustrates the foregoing description. The open design of the venturi which will minimize plugging problems and the venturi's relative insensitivity to variations in operating conditions were factors in selecting this equipment."

COLSTRIP GENERATING PLANT

Exhibit 4

FIGURE 3

II. ENVIRONMENTAL SETTING OF PROPOSED POWER PLANT

Exhibit 4

Exhibit 4

II. ENVIRONMENTAL SETTING OF PROPOSED POWER PLANT

Topography

The power plant is located just outside the town of Colstrip, Rosebud County, in southeastern Montana. The site lies in the Northern Great Plains Province, east of the ranges that make up the Rocky Mountains. The topography is developed on essentially flat lying sediments of the Fort Union Formation which contains most of the coal in eastern Montana and adjacent states. Numerous sandstones and shales are associated with the coal seams.

The Fort Union Formation was laid down as the Rocky Mountains to the west were rising during the Paleocene, about 65 million years ago. The climate was much milder and wetter at that time and the streams carried the sediments from the mountains into the Fort Union Region. In this region, there existed large swamps, producing the many coal seams now found in southeastern Montana and adjacent states. Coal in the Colstrip area is ranked as sub-bituminous and is found in seams about 25 feet thick. During erosion of the Fort Union Formation, coal seams were exposed at the surface where they were sometimes ignited, starting underground coal fires. Many areas in this region have a pink to red rock known as clinker, a direct result of underground fires.

The elevations in the vicinity of Colstrip range from less than 2900 feet (msl) in the Rosebud Creek Valley about 12 miles east of Colstrip to over 4400 feet (msl) as near as 20 miles to the south. The elevation of Colstrip itself is about 3200 feet (msl). The topography exhibits a number of land forms which have been developed on the flat lying sediments of the Fort Union Formation. The rolling upland is dissected by the streams in the area, producing narrow valleys, buttes, and some fairly level land. The level areas are the well-developed flood plains of certain stream valleys.

Colstrip lies within the upper Missouri drainage basin, on the East Fork of Armells Creek, which drains directly into the Yellowstone River. Rosebud Creek also drains an area very close to Colstrip and flows from the southwest of Colstrip to the east and then north into the Yellowstone River. The Yellowstone River flows from west to east

Exhibit 4

and is located about 30 miles north of Colstrip. There are numerous small streams in the area, most of which are intermittent, because of varying frequency and amount of annual precipitation.

Figure 4 shows the Colstrip area.

Population

The present population of Colstrip is 200. The population density in the area immediately surrounding Colstrip is very low, about one to two persons per square mile, mostly ranchers. The town of Lame Deer, population 650, is about 18 miles south of Colstrip, and Forsyth, population 1900, is about 30 miles north of Colstrip in the Yellowstone Valley. Billings, with a population of nearly 80,000, is about 90 miles west of Colstrip. Miles City lies in the Yellowstone Valley about 50 miles to the northeast. The Northern Cheyenne Indian Reservation lies south of Colstrip.

Land Use

Ranching and other agrarian pursuits comprise the bulk of the land usage in the Colstrip area. The ranches are generally a combination of grazing and dry-land crop farming. Soil and moisture are such as to permit some tillaged and irrigated agriculture in the valley bottoms, with crops such as alfalfa hay, wheat, oats, and barley.

There are some forested areas in the vicinity and a portion of the Custer National Forest lies southeast of Colstrip. Some lumbering is done in this area, but the scale is small compared to the lumbering activity in Western Montana. Coal is presently being mined in two places near Colstrip--the Western Energy Mine at Colstrip and the Peabody coal mine a few miles south. In other areas, coal is being mined by the Decker Coal Company at Decker, about 60 miles to the south, and by Knife River Coal Company at Savage, about 150 miles to the northeast.

Historical Values

The Indians were the first inhabitants in southeast Montana and staged some valiant battle efforts in defense of their territory. Custer's Last Stand and the Battle of

Exhibit 4

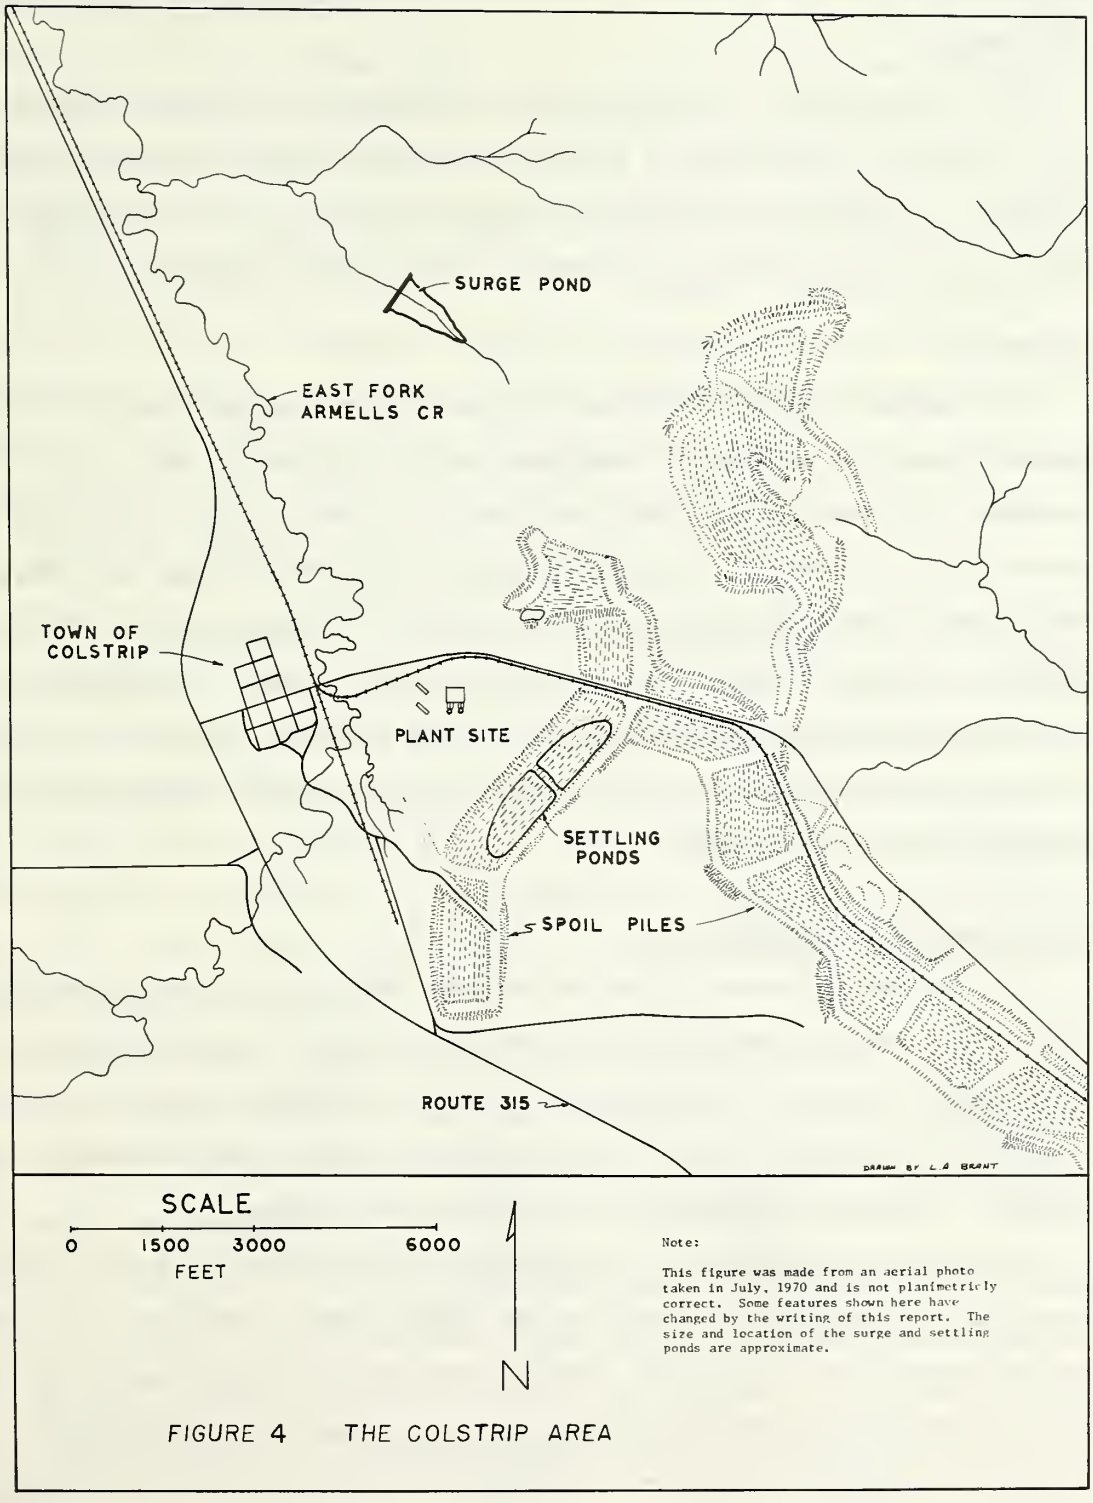

FIGURE 4 THE COLSTRIP AREA

Exhibit 4

the Rosebud are only two examples of the activity during the late 19th century in this area.

The archaeology of the proposed plant and mine site at Colstrip has been studied by a team from the University of Montana, under contract with the Western Energy Company. No significant archaeological material was found, in the opinion of the study team. The relevant portion of the study is included in the appendix.

Recreation

Southeastern Montana offers some excellent recreational opportunities. The Custer National Forest has a number of campgrounds used by local people and tourists. The pronghorn, mule deer, and whitetail deer provide big game hunting to residents and non-residents of Montana. Ring-necked pheasants can be found along the Yellowstone River Valley and Hungarian partridge, sage grouse, and sharptail grouse offer good upland bird hunting. Sport fishermen can find walleye, sauger, and northern pike in the various water courses, especially the Yellowstone River. Ponds near Colstrip have trout and there are reports that a paddlefish spawning ground is developing in the Yellowstone River near Forsyth.

Meteorology and Climatology

Southeastern Montana is in the mid-latitudes which has a prevailing westerly air flow aloft. The major east-west storm track across the U. S. passes through the center of the state. The area is considered semiarid and, as a whole, has what may be termed a modified continental climate. Within the general climate type, topographic effects provide a wide range of temperature and precipitation patterns.

The winters are quite cold, with invasions of cold arctic air from the north being occasionally interrupted by storms from the Pacific Ocean. Spring and early summer are the wettest parts of the year, with the heaviest rains coming from storms involving moisture from the Gulf of Mexico, mostly in May and June. The combination of early-growing season precipitation with rapid temperature warming in May and June, followed

Exhibit 4

by hot, dry summers has helped to produce a stable agricultural base in the arable section of southeastern Montana.

Total precipitation averages about 15 inches per year. The annual mean temperature is 46 degrees with maximum recorded high 110 degrees, and the minimum recorded low -50 degrees. Maximum hourly wind on record is 73 miles an hour, with gusts to 95 observed.

A full year's preliminary meteorological data from a study performed at Colstrip by Montana State University has been received by the state. Included in this data were wind directions, wind speeds and temperature parameters for Colstrip. The study year included the period from November 12, 1971, through November 11, 1972. Most of the wind data were collected at the top of a 307-foot tower. The inversion data were taken from thermocouple positions at the 59 and 294-foot levels on the tower with supplemental information available from aircraft soundings.

Vertical temperature profiles indicate that there were 215 inversions during the year. There were an average of about 17 inversions per month, with durations from 10 to 24 hours and 14 over the year lasting longer than 24 hours. It should be noted that the short inversions normally develop at night when air nearest the ground is radioactively cooled below the temperature of air higher in the atmosphere. These nighttime inversions usually are weak and are broken when the sun warms the ground which in turn warms the lower layers of air. Inversions of this type thus do not normally last beyond the warmest period of the day.

The short inversions, lasting between 10 and 23 hours, were most common in August, September, and October. Also, the data seem to indicate the inversions were strongest during the fall and early winter with over 24 percent of December having extremely stable atmospheric conditions.

There were generally 15 to 50 inversions per month of durations less than 10 hours.

The 14 inversions lasting more than 24 hours occurred during the winter months. There were seven in December, three in January, four in February. The longest inversion lasted 67 hours, and occured in December. Several other inversions lasted more than two days.

Figures 5, 6, 7, 8 and 9 are from the MSU data.

Exhibit 4

III. PROBABLE IMPACT ON THE ENVIRONMENT

Exhibit 4

Exhibit 4

III. PROBABLE IMPACT ON THE ENVIRONMENT

Emissions and Effects

Stack emission from the proposed power plant probably poses the greatest potential primary impact on the environment. Other aspects imposing primary impacts are cooling tower emissions to the atmosphere, ash and water discharge onto the land and direct disturbance of the land from mining. These impacts and others are investigated in varying degrees of detail in this section.

From the Final Environmental Statement for the Jim Bridger Thermal Electric Generation Project, submitted by the Bureau of Land Management for the proposed plant in western Wyoming, the following questions were raised:

1. Will the plant comply with state and federal emission and air quality standards?
2. What will be the effects of emission even if the plant complies?
3. What guarantees are there that the equipment will function as designed, and who will monitor companies in operation to see that they carry out their plans?

These questions were developed from responses to the draft environmental impact statement on that project.

The state of Montana is required to enforce federal standards established by the EPA where they are more stringent or more inclusive than state standards. For some pollutants, such as mercury, Montana has established no standards. Table 1 gives state and federal ambient air quality standards and compares them with projected maximum concentrations for the Colstrip area. Particulate, SO_2, and trace metal emissions are functions of coal composition. The estimated emissions listed in Table 2 are compared with state and federal emission standards.

Data for estimated emissions were supplied by the applicant, and projected concentrations are calculated from these figures using a simulation technique known as diffusion modeling.

TABLE 2

Exhibit 4

Diffusion modeling

A diffusion model was used to predict downwind, ground level concentrations from the two power plant units at Colstrip. A diffusion model uses various meteorological and emission parameters to predict pollutant concentrations. The modeling techniques used were approved by the EPA.[34,27]

Following are some of the assumptions made in diffusion modeling.

The concentration of emissions remains uniform in time. The material diffused consists of stable gases and aerosoes smaller than 20 microns. No material is removed from the plume when the plume strikes the ground or other object. Pollutants are distributed on a normal statistical curve from the center line of the plume.

Because of the variability of the atmosphere, diffusion modeling is considered accurate only within a factor of two. Thus, actual concentrations may be half or twice values computed.

Diffusion modeling indicates that only in rare cases will either state or federal ambient air standards be approached. That these standards are considered adequate is confirmed by the following statement by the Administrator of the Environmental Protection Agency in establishing the national primary and secondary air quality standards:

> "National secondary ambient air quality standards are those which, in the judgment of the Administrator, based on air quality criteria, are requisite to protect the public welfare from any known or anticipated adverse effects associated with the presence of air pollutants in the ambient air."

Emissions from the proposed plant are expected to drift east. The relatively high (500 feet) stacks are expected to disperse the emissions over a wide area.

No other major emission source exists within a 90-mile radius of Colstrip, therefore, no additive effects are foreseen. The Southwest Energy Study, compiled by a Federal Task Force for the Four Corners Region, indicated:

> "No significant additive effects of the concentrations covered by one plant on those of another plant if they are separated by 100 km or more."

Possible additive effects will be investigated in detail should additional plants be proposed for this region.

Exhibit 4

Particulate

Using data furnished by the applicant and quoted in Table 2, combined full load particulate emissions from both units of the plant will not exceed 267 pounds per hour (3.2 tons/day). Some increase in atmospheric particulate loading will result from the plant emissions, but these emission rates are well within both Montana emission regulations and EPA New Source Performance Standards. Control to this degree required a 99.5% collection efficiency, removing 53,200 pounds per hour of particulate from the flue gases at full load.

To give perspective to the maximum emission rate of 267 pounds per hour from the Colstrip generating facility, it can be compared to Montana Power Company's Corette Plant in Billings. The Corette plant, less than 1/3 the size, emits 426 pounds per hour under full load.

In order to determine the background particulate concentration in the Colstrip area, the State has performed sampling for almost a year. Early in April, 1972, a rural sampling site was chosen to define background ambient air values. The data from a location some nine miles east of Colstrip are presented for the period from April 6 to September 3, 1972, as follows:

TABLE 3

	Number of Samples	High Value	Low Value	Geometric Mean	Arithmetic Mean
Total Suspended Particulates (24-hr. average concentrations in ug/m^3)	23	191	3.7	22	35.5

One shortcoming of the sampling resulted from placing hi-vol particulate samplers near dirt or gravel roads because of the need for electricity. The State intends to continue sampling, possibly to the extent of establishing sites an adequate distance from roads to obtain better background data. Of the data in Table 3, the significant

Exhibit 4

value is 22 ug/m^3. For a whole year, it is estimated that the total suspended particulate value will be approximately 15 ug/m^3. The national secondary standard is 60 ug/m^3 which is four times the particulate background value estimated for the Colstrip area.

Maximum ground level concentrations for various pollutants have been obtained from diffusion modeling estimates as presented in the following section on sulfur oxides.

From modeling, a 2 ug/m^3 plant contribution for a 24-hour average (Table 5) was estimated with adverse weather conditions. This value is very low compared to the national 24-hour secondary standard of 60 ug/m^3 for total suspended particulates. Considering the background value of 15 ug/m^3, the addition of the 2 ug/m^3 value results in a total estimate of 17 ug/m^3.

However, one must consider road dust, which will increase due to greater population and mobility of that population, construction, and plant and mining operations. It is anticipated that an annual geometric mean for the area might approach 50 ug/m^3.

TABLE 4

MAXIMUM GROUND LEVEL CONCENTRATIONS FOR TWO 350 MEGAWATT UNITS

Period / Pollutants	10 min.	1 hour	3 hour	24 hour	Annual
Particulates (ug/m^3)	-	-	-	2.0	0.10*

Fluorides (PPB)	.183	.14	.11	.020	.0012*

*EPA Diffusion Model

Exhibit 4

Sulfur Oxides

Data submitted by the applicant and listed in Table 2 specify that sulfur oxide emissions from the proposed Colstrip plant will not exceed 1 lb/million BTU input to the system. This totals 6820 lbs/hour for the two units (82 tons per day) representing emission control efficiency of approximately 39%. Coal analysis reveals an average of 0.77% sulfur-in-coal.

Montana regulations limit emissions to 1 lb of sulfur/million BTU input or the equivalent of 2 lbs of sulfur dioxide/million BTU input. Federal New Source Performance Standards for Fossil Fuel-Fired Steam Generators limit sulfur dioxide emissions to less than 1.2 lbs/million BTU input.

The following paragraph, taken from the applicant's permit application, explains the proposed sulfur oxide control system at the plant:

> ". . .This is a full stream scrubber system that will simultaneously remove fly ash and sulfur dioxide. The removal is accomplished by scrubbing the flue gas with an alkaline solution of water and calcium carbonate, which is generally available from the fly ash. If the alkalinity of the ash varies to a point where additional alkalinity must be added, it is obtained by the addition of soda ash (Na_2CO_3) or lime (CaO). The gaseous sulfur dioxide will react with the calcium carbonate to form solid calcium or sodium salts. At the same time, the mechanical action of the scrubber traps fly ash particles in the water droplets. Recirculation within the scrubber system makes the alkalinity in the ash available for the process. The used scrubber solution, newly formed salts, and trapped fly ash are piped to an ash pond where the solids settle out. The pond water is then recirculated back to the scrubber in a closed loop system from which no water is discharged to any natural bodies. This emission control system is guaranteed to limit the sulfur oxide emissions to 1.0 lb SO_2/million BTU and the fly ash emissions to .018 grains per actual cubic foot, at any operational load of the power plant."

Background sulfur dioxide values have been gathered in the Colstrip area for a one-year period (September, 1971, - September, 1972). See Figures 10 and 11, Appendix, for maps of the sampling sites in the general area. The data were obtained from monthly sulfation plate data using the conversion factor (mg $SO_3/100cm^2/day$) x 0.035 = parts per million. See Table 16 in Appendix.

Exhibit 4

TABLE 5

Sulfur Dioxide (ppm)	
Number of Samples	54
Annual Arithmetic Mean	0.003 ppm

This arithmetic mean of 0.003 ppm should be significant as an average background value for the Colstrip area at present. Continued sulfur dioxide monitoring will be carried out by the State Department of Health and Environmental Sciences.

The draft statement estimated a maximum SO_2 concentration of .43 ppm, which would have violated the Montana standard requiring that .25 ppm of SO_2 for one hour not be exceeded more than once every four days.

Following publication of this draft, new information became available that indicated the SO_2 estimate in the draft was erroneous. The model and its results were refined with data from TVA power plants and supplemental meteorological information from Montana State University. Revised figures indicate SO_2 concentrations would not exceed .136 ppm under severe fumigation conditions.

Referring to Table 4, we again find conservative one-hour, three-hour, 24-hour, and annual estimated SO_2 concentrations. The state's annual SO_2 background value of 0.003 ppm is higher than the annual value of 0.001 ppm estimated by the EPA. It is possible that the annual average could be slightly in excess of 0.004 ppm.

The diffusion model was used to estimate particulate, sulfur dioxide, and nitrogen oxide concentrations.

A different model similar in design and theory was used by the EPA to estimate long term (annual) concentrations. Their results listed in Table 4 indicated no violation of the annual standards.

Estimates for oxides of nitrogen and particulate were made by multiplying the SO_2 results by the respective ratios of SO_2 emission to nitrogen oxide and particulate matter.

Exhibit 4

The state's experience in ambient monitoring of other industrial complexes around the state suggests that one-hour SO_2 concentrations approximating one part per million do occasionally occur under adverse weather situations. The terrain surrounding Colstrip does not rule out wind channeling, impingement and other phenomena which might cause higher SO_2 concentrations in the Colstrip area than the above diffusion predictions. A similar discussion could be developed for other emissions.

Nitrogen Oxides (NO_x)

The boiler supplier for the proposed plant guarantees nitrogen oxide emissions will not exceed .7 lbs NO_x/million BTU, the level specified in the Federal New Source Performance Standards. When the Colstrip plant is operating at full load, this amount will total 4750 lbs per hour of nitrogen oxides.

The following information was submitted by the Montana Power Company regarding NO_x emissions:

> "The steam generators at this installation will both be tangentially fired pulverized units.
>
> "In order to insure an absolute minimum of nitrogen oxide formation, we have purchased an overfire air system as part of this equipment. This system takes the normal amount of combustion air and distributes it to a greater volume of the furnace than would normally be used in a tangentially fired unit. The greater distribution of combustion air reduces the maximum flame temperatures and the amount of nitrogen available for combination at any particular location in the flame. As a result, nitrogen oxide products will be substantially reduced below the low levels normally found on a tangentially fired unit.
>
> "With the overfire air system, the supplier, Combustion Engineer, Inc., has guaranteed that the nitrogen oxides leaving the unit will not exceed .7 lbs/million BTU, which we understand is the current federal emission standard."

In its Background Information for New Source Performance Standards, the EPA stated:

> "The NO_x standard for solid fuels is based on results from tangentially fired units burning coal. Four tangentially fired units burning bituminous coal, which were tested by EPA, had emissions of nitrogen oxides that were well below the required level of 0.7 pounds per million BTU. Published data from numerous sources, and other test results from steam generator manufacturers, indicate comparable results for tangential firing . . ."

Exhibit 4

The State has done no background ambient sampling for nitrogen oxides. The EPA AP-84 publication "Air Quality Criteria for Nitrogen Oxides", page 3-1, states that the non-urban North American continental average levels of NO_2 are about 0.004 ppm. The source of this background NO_2 is biologically produced NO which under photochemical oxidation yields the NO_2 variety.

Extrapolation from the SO_2 dispersion model indicate low concentrations of nitrogen dioxide will result from the proposed plant.

Trace Elements

The quantities of most of the trace elements in Montana coal are not well known. The only element that has been analyzed sufficiently to warrant any confidence in the results is fluorine. Table 6 presents the best data that the state has on the elements shown.

TABLE 6

TRACE ELEMENT CONCENTRATIONS OBTAINED FOR COAL
FROM WESTERN ENERGY MINE AT COLSTRIP

(Values in ppm by weight unless otherwise noted)

Al	0.74%	0.74%	Eu	.075	.085

R^{226}	2.8	pCi/g* (Mean of six other Montana coals - 3.31*)			

Values obtained by Battelle Northwest for EPA except*
*Values obtained by EPA

Trace element concentrations in the coal only partially determine adverse environmental effects. The form in which a particular element leaves the boiler will

Exhibit 4

partially determine how it is affected in the control devices and its behavior in the environment. There are few plants of the Colstrip type with venturi scrubbers, and how their operation affects trace element emissions are not known at this time.

Certain trace elements are of particular interest and will be dealt with separately.

Fluorine

Values for the concentration of fluorine in the coal at Colstrip have ranged from less than one ppm to 140 ppm. Since the writing of the draft statement, the state has performed a number of analyses for fluorine in the coal according to standard procedures. Since that time, some other laboratories have revised their values and there is now general agreement among two commercial laboratories and the state on a value between 30 to 40 ppm dry weight on splits of seven samples. A third commercial lab reported a mean value of 25 to 30 ppm for these same seven samples. These values correspond with the state's values for other samples of coal also from the Rosebud Seam at Colstrip. Therefore, the very high (>100 ppm) and the very low (<5 ppm) values seem to be in error.

Also, since the writing of the draft supplement to this statement, this Department has analyzed the collected ash from the Corette plant for fluorides and has sampled fluoride emissions from the stack gases also at the Corette plant. The presence of fluoride in the various kinds of ash show that not all of the fluoride in the coal is released into the air. In addition to these data, a series of tests have been run on a pilot venturi scrubber to determine fluoride removal efficiencies. These tests indicate that about 90 percent of the total fluorides will be removed by the wet scrubber. Taking all the data we have regarding fluorine, we can estimate the emission rate of fluorides and use this figure and the diffusion model to arrive at worst possible ambient concentrations.

Assuming 35 ppm fluorine in the coal, 585,300 pounds (dry weight) of coal burned per hour, and only 10 percent of the fluorine emitted into the air, we arrive at an

Exhibit 4

emission rate of 2.05 pounds fluoride per hour (.26 g/sec). At this emission rate, the maximum 24-hour concentration that can be expected is .02 ppb as compared to the state standard of 1.00 ppb for a 24-hour average.

Mercury

It is difficult to analyze coal for mercury and obtain reliable values. Since mercury is quite volatile, it may evaporate from a coal sample during handling and the sample may easily be contaminated in the laboratory. This problem is difficult to overcome even with the most careful handling. Even samples prepared for use as standards

Exhibit 4

can show variation in the mercury content (Norm Suhr, personal comm.). The author of a recent article in Science which reported 33 ppm Hg in a sample of Montana coal (considered a very high value) has said recently that the value is in error, probably the result of contamination of the sample.[16,17]

A commercial laboratory under contract with Montana Power Company reported that mercury concentrations in the Rosebud Seam are less than 0.1 ppm. Given the difficulties associated with mercury analyses and the unreliable data obtained from this laboratory on another trace element, the mercury value cannot be relied upon.

There are no reliable data concerning mercury in Montana coal. However, the state has no reason, at this time, to think Montana coal has either more or less mercury than coals from other parts of the U. S. (1-3 ppm).[7]

The laboratory working for Montana Power Company reports that 97 percent of the mercury remains in the ash. The Department does not accept this conclusion. Other reports indicate approximately 90 percent of the mercury in the coal is emitted into the atmosphere as a vapor.[8] What effect the wet scrubbers, with their lower temperatures, will have upon the mercury vapor is not known. It is likely, though, that the wet scrubbers will remove a higher percentage of the mercury than other types of control devices in use on most of the coal-fired power plants in the U.S.[11,31]

Selenium

Selenium compounds released in the combusion of coal may be either gaseous or particulate. In either case, they would be collected at a high efficiency by wet scrubbers. The particulate would be expected to be collected at close to 99 percent efficiency, just as other particulate matter. The gaseous portion, probably hydrogen selenide, is extremely soluble in water, thus lending itself to collection in wet scrubbers.[32]

Radioactive Elements

Several of the trace elements are of particular interest because they are radioactive. Uranium is not very abundant in the earth's crust but it is found in many

Exhibit 4

kinds of rocks. Being radioactive, uranium breaks down into lighter elements. At that time, it emits some form of radiation. The new elements which result from a uranium decay are called daughter elements, some of which are also radioactive. The radioactive daughter elements also undergo decay until a stable isotope is formed. There are a number of isotopes in the uranium decay series between uranium and lead. Some isotopes have a very short half-life (time for one half of a given quantity of a radioactive substance to disintegrate) and some have long ones. Uranium^{238} has a half life of about 4.5×10^9 years. This long half-life enables the element to be acted upon by geological processes which may concentrate the element in certain kinds of rocks. Some coal and black shales have anomalously high concentrations of long-lived radioactive isotopes. The isotopes with short half-lives can be formed and undergo decay while in the coal (age of Colstrip coal is about 60 million years). However, these isotopes are continuously being formed by the heavier isotopes.

Natural radioactivity of some of the Colstrip coal has been determined. The small amounts of uranium and thorium with their long half-lives are not likely to pose any threat to the environment. Radium^{226} is the most likely to pose a threat.[21] (The units for radium^{226} in Table 7 are picocuries per gram of coal. The term picocurie (10^{-12} curies) is a unit of activity, not a unit of mass. The activity unit is used here to separate R^{226} from other radioactive isotopes, each having its own level of radioactivity (half-life). The activity units can be treated as mass units in diffusion modeling and since it is activity that is of interest, the exchange of units is acceptable.)

By figuring the amount of activity of R^{226} which goes through the boiler and applying the diffusion model, an ambient activity can be obtained for groundlevel under the worst meteorological conditions expected. Assuming 3.0 pCi/g (dry wt) for an average value of radium activity in the coal, 796×10^6 pCi/hr will be present in the coal going to the boiler. Because the radium will be in the particulates, we will assume 99 percent collection in the scrubber.[12] A level of activity of

Exhibit 4

2210 pCi/sec will be emitted to the atmosphere. Applying the diffusion model, we find a maximum value of 9.2×10^{-4} pCi/m^3 in the ambient air at ground level. The maximum permissible concentration set by the Federal Radiation Council is 1×10^{-12} uCi/ml or 1.0 pCi/m^3, for radium in soluble form (or twice that value if insoluble). Therefore, maximum radium^{226} concentrations are expected to be three orders of magnitude less than those values considered safe. From these figures, the Department concludes that no radiation danger is expected from the proposed power plant; however, sampling for radioactivity will be carried out once the plant goes on line to experimentally ascertain the correctness of this conclusion.

Other Trace Elements

A symposium on trace elements in coal was held at the annual meeting of the Geological Society of America in November, 1972. From the papers presented and the discussions which followed, several conclusions can be tentatively drawn.[1]

First, many trace elements are rather efficiently captured in the plant when good particulate control is in operation. From work done in Australia, it appears that in chain grate and stoker fired boilers, most of the trace elements are collected in the slag, ash, and boiler tube deposits. The boiler tube deposits immediately next to the tube have much higher concentrations of the trace elements, which may be the result of greater cooling in that zone of the deposit. In pulverized coal boilers, such as the proposed Colstrip plant will have, the trace elements collect in the fly ash. These situations hold true even for the more volatile elements such as arsenic, zinc, and lead. No information is available from this study for wet scrubber systems but if cooling is a factor in concentrating trace elements on the boiler tubes, the degree of cooling in the wet scrubber may be expected to make that system more effective in removing trace elements than other kinds of control devices.

Second, a speaker from EPA (Von Lehmden) reported that there are some indications that smaller particles have higher concentrations of the trace elements than the larger

Exhibit 4

ones. He stressed that the data only indicate the possibility of the existence of this phenomenon. If this phenomenon exists, one could not assume the same efficiency of removal of trace elements by the scrubber as the efficiency of particulate matter, since the scrubber is less efficient in removing the smaller particles. However, a concentration factor of two in the uncollected fly ash would reduce the efficiency of trace element collection from 99.5 percent (total particulate collection efficiency) to 99 percent, assuming all of the trace element is in the fly ash. Because the concentration factor in the escaping particulate matter is probably less than two, and because some of the trace elements are collected before they reach the scrubber, an efficiency of 99 percent for particulate trace element removal can be assumed if the overall particulate efficiency of the scrubber is 99.5 percent.

Trace Elements in the Collected Ash

Some concern has been expressed concerning the fate of the trace elements in the collected ash and if these elements can enter ground or surface water. The trace elements in the ash differ from those in the coal in two important ways. First, the burning of the coal recombines the elements into different compounds. Second, the concentrations of the trace elements in the ash may be elevated over those in the coal.

The oxidizing environment and high temperatures in the boiler are generally expected to produce oxides of the elements. Most oxides are quite insoluble and will remain in the ash. This Department is not aware of any trace element contamination existing from leaching of the coal, fly ash that is used in concrete, and other materials, or from leaching of the clinker (the ash and baked country rock resulting from natural underground coal fires.) The clinker perhaps deserves some investigation in this area because of the reducing conditions which probably existed during the combustion of that coal. In this case, the trace elements may exist in less oxidized states and be more soluble than in the power plant ash. If the leaching of trace elements does become a problem, ash disposal methods may be altered to alleviate the problem.

Exhibit 4

Conclusion

Although many questions exist concerning possible trace element contamination from the proposed plant, no significant problems are expected at this time. This situation does not eliminate the state's concern in this area and investigations are continuing to answer some of the questions. Monitoring by the state agencies and research organizations probably would discover any problems that might arise which are not anticipated at this time. Problems related to trace elements, if found, will have to be dealt with on an individual basis.

TABLE 8

Hi-vol analyses at a site 9 miles east of Colstrip are as follows:

Values are 24-hour averages in ug/m^3	No. Samples	High Value	Low Value	Geometric Mean	Arithmetic Mean
Total suspended particulate	23	191	3.7	22	--
Cadmium	20	0.001	0.000	--	0.0002
Lead	20	0.011	0.000	--	0.065
Zinc	20	0.290	0.010	--	0.1235

The above heavy metal data were obtained by chemical analyses of the hi-vol fiber-glass filters.

Exhibit 4

Possible Impacts From Emission

Sulfur Oxides

Many of the effects of sulfur oxide emissions have been documented.[4] Metallic surfaces may be damaged with the damage increasing with increasing humidity and temperature. Other materials affected by SO_2 are limestone, marble, roofing slate, mortar, some textile fibers, such as cotton, rayon and nylon, and leather and paper. Synergistic interactions with particulate matter contribute to the effects. Sulfur oxides can also damage various forms of plant life.[4]

Sulfur oxides generally accelerate corrosion when they are first converted to sulfuric acid, either in the atmosphere or on metallic surface. Tests in Chicago showed that 100 gram mild steel panels exposed to average sulfur oxide concentrations of 0.02 ppm lost about four grams of their weight through corrosion within three months.[4]

Plants vary in their sensitivities to sulfur oxides. Among the plants existing near Colstrip, alfalfa is believed the most sensitive to SO_2. Experiments have shown that 1.25 ppm of SO_2 will cause traces of leaf destruction in one hour. Four ppm caused 50 percent leaf destruction in the same time.[4] It has been suggested that lower concentrations of SO_2 over long periods may slow the growth rate of sensitive plants.[4]

There are two types of visible leaf injury, acute and chronic, associated with SO_2. Acute injury is caused by relatively high SO_2 concentrations over relatively short intervals. Chronic injury results from exposure to relatively low concentrations over a period of days or weeks. It occurs when an excessive amount of sulfate accumulates in leaf tissue. Sulfate formed in leaf tissue from SO_2 in the air is additive to sulfate absorbed through the roots. Absorption through the roots thus increases as SO_2 in the air precipitates sulfate into the soil. It should be noted that sulfates precipitating from airborne SO_2 may enrich sulfate-deficient soil. The sulfate content of soils near Colstrip is not known.

In addition to visible damage, it has been suggested that the growth of alfalfa and other sensitive species might be suppressed at SO_2 concentrations too low to produce visible injury.[4]

Exhibit 4

Another possible source of damage from SO_2 emissions results from the formation of sulfuric acid mist, the combination of airborne sulfur oxides with water. The amount of acid formed depends on the temperature, humidity, and the amount of sulfur oxides in the air.

Some types of pine trees are sensitive to sulfuric acid solutions, and substantial damage to commercial Christmas tree crops has been reported in an area dominated by the Mt. Storm power station at Mt. Storm, West Virginia.[22,14] Although the damage apparently was caused by acid rains, it should be noted that the Mt. Storm plant emits an estimated 120,000 tons of sulfur oxides per year, compared to about 30,000 tons at the proposed Colstrip plant.

Heavy SO_2 emissions also can lead to acidification of soil and water. Studies in Scandinavia indicate that the pH of surface water in that area has extended farther into the acid range over a period of 11 years.[37]

The increasing acidity is believed to result from the heavy industrial pollution drifting over the area from southern England and central Europe. Sulfuric acid in precipitation is believed to cause the acification.

While in England, SO_2 concentrations declined at ground level because of the increasing use of tall stacks. However, downwind in Scandinavia the acidity of rainwater increased. It is assumed that the delivery of the pollutants to higher air levels by taller stacks caused the delivery of the pollutants to stations farther downwind than before.

In 1958, the pH of rain was between 5 and 4.5 in areas of Europe downwind from major pollution sources. One exception was the Netherlands, where the pH was lowered to 4.5 from the buildup of pollutants from southern England, northern France, and the Ruhr. Seven years later, the pH was under 4.5 over most of central Europe and southern Scandinavia, and under 4 in the Netherlands and northern Germany.[37] The trend to acidification apparently is increasing with industrialization.

Exhibit 4

Surface water in Scandinavia became two to three times more acid over a three-year study period. This is expected eventually to affect fish populations. Salmon can tolerate a pH no lower than 5.5, trout 5, pike 4.3, and perch 4.[37] Where acidic precipitation is heavy, important minerals may be washed out of soils.[25]

The amount of SO_2 emitted from the proposed Colstrip project probably would be insignificant compared to that causing the effects noted in the Norwegian study cited. Other coal development facilities known to be under consideration in the area could lead to significant damage from SO_2.[29]

On a worldwide basis, man is believed to be contributing about half as much as nature to the total atmospheric burden of sulfur compounds. By the year 2000 he will match nature's contribution.[18] In industrialized regions the SO_2 concentrations contributed by man are overwhelming natural processes, and causing the dispersal of sulfur compounds for many hundreds of kilometers downwind from industrial sites.

Fluorides

According to the U. S. Department of Commerce, about 155,000 tons of man-made fluoride is emitted to the ambient air annually. Of this, 17 percent, or 27,000 tons, comes from the burning of coal.

Although the State ambient standard of 1 ppb for a 24-hour average is considered adequate, the effects of fluoride emission over the life of the proposed plant are unpredictable. Exposure to low concentrations over long periods can lead to damage in sensitive plants. In studies some plants exposed to .1 ppb for five weeks developed substantial leaf damage and accumulated 150 ppm of fluoride.[30]

Ponderosa pine, which is common around Colstrip, may be damaged by fumigations of hydrogen fluoride at a concentration of .5 ppb.[13]

Also, in some cases it appears that ambient concentrations below 1 ppb may cause fluoride concentrations in vegetation sufficient to harm domestic animals. A recent study by the Washington Department of Ecology found that an aluminum plant near Ferndale,

Exhibit 4

Washington, was causing fluoride concentrations in the ambient air of .4 ppb. Plants in the nearby area accumulated 20 to 180 ppm of fluoride, and cattle were crippled from eating contaminated forage.

Most veterinarians who have studied fluorides agree that at least 35 ppm in forage is necessary to cause harm to domestic animals.[13]

It should be recalled that bunch grasses growing in the Colstrip vicinity have a life cycle lasting from three to five years, allowing more than one growing season for the accumulation of fluorides.

Most studies indicate that domestic animals raised in areas not polluted by fluorides will accumulate in their lifetimes less than 1000 ppm of fluorides in their bones. In polluted areas, animals will accumulate between 1000 and 8000 ppm, depending on the severity of the pollution.

Domestic animals do not exhibit the same fluoride-accumulating propensities as wild animals.[5] Data published by the EPA in 1972 showed the following:

1. Indigenous animals such as mice, rabbits, squirrels, chipmunks, deer, elk, bear, antelope, coyotes, and grouse collected in areas where vegetations contain 10 ppm or less of fluoride will average less than 300 ppm in their bone tissue.

2. Animals of the same species living in a fluoride-polluted area will accumulate two to five times more fluoride in their bones than domestic animals living in the same area.

3. Deer and snowshoe hares feeding upon forage with an average fluoride concentration of 30 ppm will accumulate 2000 to 5000 ppm of fluoride in their bone tissues, while grouse species (blue and ruffed) feeding on forage with 30 ppm of fluoride will accumulate 3000 to 7000 ppm in bone tissues.

There was no attempt to evaluate health effects caused by fluorides in the wild animals.

Exhibit 4

Particulate Matter

The extent of impacts resulting from particulate emission is not completely known. On a worldwide basis, suspended particulate matter is believed to be at least partly responsible for lowering the temperature of the planet, through the refraction of inbound solar energy.

The most obvious impact from particulate matter emitted at Colstrip probably would be visibility. The efficiency of venturi scrubbers is known to be low on particles less than two microns.

A given mass of particulate matter, such as one pound, will refract light in the atmosphere according to the amount of surface presented to the light rays. One pound of particles 2 microns in diameter would have far more surface area, for example, than two much larger particles each having a mass of one-half pound. Thus, even the 99.5 percent efficiency predicted for the scrubbers at Colstrip will not totally prevent visibility reduction. There is reason to think that under stable conditions, with high humidity, visibility may decrease.[3] Visibility will decline as humidity rises.

Another contribution to lowered visibility will be the conversion of sulfur oxides and nitrogen oxides to sulfate and nitrate particles in the air.

The Southwest Energy Study commented thus on visibility reduction:

> "A review of available information on conversion of SO_2 and NO_x to particulate matter in plumes indicates that there is no information on conversion of NO_x to nitrate and the information on conversion of SO_2 is not very reliable and is in quantitative disagreement. However, it is clear from chemical analysis of collected particulate matter that SO_2 and NO_x are converted to particulate sulfate and nitrate.
>
> "If there is significant conversion of SO_2 and NO_x to particulates this will predominate over fly ash in causing visibility reductions.
>
> "Aircraft studies in power plant plumes have reported that as much as 50 percent of the gaseous SO_2 disappears (presumably to particulate sulfate or sulfuric acid) within ¼ mile of the stack exit."

Since the abatement equipment on the proposed plant would be similar to the equipment on the Dave Johnston plant, it is germane to note that there is almost no visible particulate matter in the scrubbed stack gases of that plant.

Exhibit 4

Further possible impacts of particulate emissions will be discussed under health effects.

Mercury

Because of the lack of any reliable analysis of mercury in the Colstrip coal and ignorance regarding the efficiency of venturi scrubbers on mercury vapor, no predictions can be made about possible effects. The movement of small amounts of mercury through the food chain may cause liver or kidney concentrations in range cattle to exceed federal tolerance limits without visible damage to the animals if mercury emissions are high enough.

A concentration of .17 ppb in water appears capable of producing levels in fish flesh of .5 ppm, which is above acceptable levels for human consumption on a regular basis.[19]

Selenium

Selenium is poisonous to men and other animals in high concentrations. At lower concentrations it is a necessary dietary substance. No impact should result from selenium emissions at Colstrip, owing to the high collectability of selenium compounds in wet scrubbers.

Impacts of Emissions in Combination, Health Effects

Although synergistic effects are certain to occur among emissions from the proposed plants, the potential for damage is impossible to assess. It is possible to assert that the combined effects of all the pollutants will be greater than the accumulated effects of each pollutant existing alone. For example, particulate matter acts with sulfur oxides to increase the irritant capabilities of the combination. A threefold to fourfold potentiation of the irritant response to sulfur dioxide is observed in the presence of particulate matter capable of oxidizing sulfur dioxide to sulfuric acid.[3]

Exhibit 4

Both ozone and nitrogen oxide react with SO_2 to cause plant damage at concentrations much lower than those needed for either pollutant to damage plants alone.[4]

Acting alone, nitrogen oxides are an irritant to the human respiratory system. Combined with water in the air, NO can become corrosive nitric acid.[2]

The team hired by the applicant to study emission effects at Colstrip indicated that some plant damage might result at Colstrip if the oxides of nitrogen are released in sufficient quantity during early summer, when plants are growing rapidly. (See Appendix)

In the human body SO_2 acts to cause increased resistance in the airways of the lungs. Most individuals react to SO_2 at concentrations 5 ppm and above, although sensitive persons experience discomfort at 1 ppm. The long-term effects of SO_2, particulate sulfates, and sulfuric acid mist are not agreed upon, although it generally is conceded that sulfur oxides lead to a variety of respiratory ailments.

A letter to the State from Dr. Bruce Anderson, Billings, (see Appendix) indicates that patients with respiratory ailments in Billings get noticeably worse when a temperature inversion traps pollutants.

Dr. Bruce Geer of Durango, Colorado, testified before a U. S. Senate Committee that acute and chronic respiratory ailments in children admitted to Durango hospitals doubled in five years during the operation of the Four Corners coal-fired power plant, although the population of the areas served by the hospitals decreased.[28] Dr. Geer attributed the increased illness to air pollution from the plant. It should be noted that the Four Corners plant emits an estimated 300 tons of SO2 daily, compared to 82 tons per day at the proposed Colstrip plant.

Nevertheless, it is interesting that emphysema and chronic bronchitis are among the fastest growing diseases in the country, doubling every five years since 1945.

The extremely small particulate matter that would be emitted at Colstrip could be more detrimental to health than larger amounts of coarser material.[3] This is because

Exhibit 4

microparticulate matter, smaller than 2 microns, penetrates more deeply into the air passages of the lungs, where it may hinder air exchange. Further, the smaller particles in this range may penetrate the minute air sacs of the lungs where they come into direct contact with the blood. They may then be transmitted throughout the body, along with attached toxic materials. The smaller particles also can carry more toxic material than an equal weight of larger particles because of the greater area of the smaller particles.

There also is evidence that particulate matter may increase precipitation where humidity is sufficient.[23]

Although humidity at Colstrip is low, it likely would be increased by emissions from evaporative cooling towers. Besides possibly increasing precipitation and decreasing visibility, increased humidity from cooling towers could cause increased generation of sulfuric acid if the cooling tower plume were to mix with the stack plume.

Such mixing of the plumes should be infrequent because of the large vertical difference of the emissions, and the probable difference in wind direction between the 65-foot level cooling tower emission and the 500-foot level of the stack plume. Despite the apparent odds against plume mixing, it does happen at existing power plants. Regardless of whether the plumes mix, the cooling towers produce a detectable increase in humidity for many miles downwind.[23]

Under the proper weather conditions, wet cooling towers can produce icing and fog conditions, although this usually does not extend more than one-quarter mile from the towers.[26] Only the power plant will be within one-quarter mile in the prevailing wind direction from the towers. The applicant indicates that the Bechtel Corporation believes fogging or icing will not occur more than 200 feet from the towers.

Noise

The only significant noise at Colstrip will be produced by the cooling towers. Using information furnished by the applicant, the state developed the following chart.

Exhibit 4

TABLE 9

Noise level (both towers) in db(A)	distance in feet
84	100
78	200
72	400
66	800
60	1600
54	3200
48	6400

There is no federal or state noise standard, but some Montana towns have noise ordinances. In Billings and Helena, for example, the maximum noise allowed during the day is 55 db(A), with 50 the maximum at night. From information furnished by the applicant, it appears there is a trailer park planned about 1500 feet from the towers. At that distance, the sound level might be bothersome. Even at the far side of Colstrip, about 3000 feet from the towers there will be noise in excess of the municipal ordinances for Billings and Helena. The towers will also be 3000 feet from the applicant's property line.

Cooling tower drift

Information from the applicant on cooling tower drift follows.

> "At an expected drift loss of 0.005 percent of 104,000 GPM (5.2 gpm) the solids carryover would not exceed 10.9 pounds per hour. By analogy . . (with information furnished by Bechtel) all of the material would be deposited within a 2000 foot radius of the towers and 60 percent or 835 pounds/acre/year within a 1000 foot radius. These figures apply to continuous operation at full load, whereas actual operation would average about 70 percent of maximum."

Bechtel estimated the flora damage threshold at 1000 pounds/acre/year. It should be noted that the 2000 foot radius is all company land.

The cooling tower water will have the following maximum composition:

Exhibit 4

Total hardness, ppm as $CaCO_3$	1,859
Calcium, ppm as $CaCO_3$	1,167
Magnesium, ppm as $CaCO_3$	682
Alkalinity, M, ppm as $CaCO_3$	32
Alkalinity, P, ppm as $CaCO_3$	0
Chloride, ppm as Cl	76
Sodium, ppm as Na	483
Silica, ppm as SiO_2	166
Nitrate, ppm as NO_3	6
Sulfate, ppm as SO_4	2,646
Bicarbonate, ppm as HCO_3	39
pH	7.2 ± 0.2
Total dissolved solids, ppm	4,045

Other impacts

Ash and Water Discharge to the Land

Dust from Ash

Fly ash, bottom ash, and economizer ash are sluiced to the ash pond system for settling. When the settled ash fills an individual pond to capacity, the water is drained off to another pond and the ash is removed.

The two possible sources of dust from this operation appear to be of only minor impact. First, dust may be generated from the surface of a dry inactive pond prior to or after ash removal. Second, dust may result from ash handling and disposal.

The applicant has indicated ponds will be kept flooded at all times, especially if it appears a dust problem may arise. The applicant has also indicated measures will be taken to reduce dust from ash handling. Data on physical properties of the ash indicate that the ash does not easily become airborne. This is especially true at the pond where it has a tendency to form a hard crust.

There is some chance of water contamination if the applicant fulfills the stated intention of disposing of ash in worked-out strip mines.[29] The pollution potential has not been determined, and the State Department of Lands indicates that no fill of ash into mines will be allowed until it is proven that water contamination will not occur.

Exhibit 4

Water Contamination - Plant

The closed recycling water system prevents any wastewater discharge to groundwater or streams. All water leaving the plant is discharged directly to the atmosphere from the stack, cooling towers, and ponds. Approximately 6250 gallons per minute of water evaporate from the cooling tower-condenser system, and 500 gallons per minute leave the stack.

Blowdown, consisting of mineral-laden water from the boiler-turbine system, discharges to the ash pond. The minerals eventually are concentrated by evaporation and precipitate in the pond.

Water Contamination - Colstrip Sewage System

An Imhoff Tank, which provides settling and removal of suspended material, is presently used for sewage treatment. On May 8, 1971, the Montana Water Pollution Control Council adopted the following compliance plan for the community of Colstrip:

Begin construction of new sewage treatment facilities by September 1, 1971.

Complete construction of new sewage treatment facilities by January 1, 1972.

Plans and specifications were received for the project during April, 1971, and after requested changes were made, they were approved on October 14, 1971. A county rural improvement district was formally established for the project during October, 1971. Construction of the sewage lagoons began during September, 1972, and was completed in January, 1973. Design of the facility was based on a projected 1990 population of 880.

Because there is essentially no flow in Armells Creek, it is necessary to have a facility which will provide removal of essentially all waste materials contributed by the population or to provide a facility which is capable of treating the sewage adequately, holding it to a time when there is adequate dilution flow in Armells Creek, and discharging it at that time. It may also be possible to discharge the treated water to the Montana Power Company cooling water ponds when they are constructed. It

Exhibit 4

is doubtful that there will be any discharge from the sewage lagoons for several years. Aeration equipment can be easily added to the lagoons if an odor problem arises or if additional treatment is required.

The State recommends that water from the sewage lagoons be used for irrigation after water is available from the pipeline. Water from the deep well, although not harmful to humans, is too highly charged with sodium salts to be used for irrigation.

A more detailed discussion of sewage disposal is presented in "Water Quality Management Interim Plan for Colstrip, Montana" prepared by the Montana State Department of Health and Environmental Sciences.

After reviewing the potential for water pollution from the ash ponds and sewage lagoon, State water pollution authorities concluded the chance of ground or surface water pollution was slight at most. Chemical-charged water will be confined in ash ponds sealed with bentonite, plastic, or whatever other material emerges as most favorable from research now being performed by the applicant.

The new sewage lagoon is adequate for 980 persons. However, according to the town plan developed for the applicant, permanent population of the town would surpass 980 in late 1973, climbing to a total permanent population of 1781 in 1975, and remaining stable until at least 1980. If all these persons live in the town, enlargement of the sewage facilities will be necessary, and the state would require this if necessary to prevent water pollution.

Adequacy of water supply

Colstrip currently is supplied by several shallow wells and a cistern. The supply is deemed "barely adequate" by the state. It is proposed to divert 150 gpm from a new 9000-foot deep well to municipal use. Ample water could be supplied from the pipeline that would supply the proposed plant from the Yellowstone River.

Exhibit 4

Land Use

The construction of the proposed power plant with its associated aqueduct, transmission lines, roads, mine and so forth, represents a major change of land use. The agrarian and wildlife uses of thousands of acres will be converted into industrial use.

The plant, as proposed, will occupy an area of 1365 acres. The mine will disturb an area of approximately 2000 acres over 30 years. The aqueduct and transmission line will temporarily alter approximately 2900 acres. However, most of the area involved in the aqueduct and transmission line rights-of-way will not be out of production. Roads along these rights-of-way may permanently change the land use of about 200 acres.

The greatest land use changes may not come from the proposed activities directly, but from the greater numbers of people in the vicinity. The increased population, especially during construction, will possibly result in trailer parks, subdivisions, drive-in businesses, service stations, and many other features that will alter land use. The growth of the town of Colstrip is being planned but the increase in area will alter land use.

Impact on Flora and Fauna

The construction of the proposed plant, the mine, stack emissions and the general increase in human activity will affect the flora and fauna. The effects would be produced in the following ways:

1. Occupation of land by other than natural habitat.
2. Presence of man-made structures.
3. Increased noise, pollution, and other factors affecting the functioning of the ecosystem.
4. Increased activity of man, including greater hunting pressure by the increased population.
5. Effects on aquatic systems by changes in quality and quantity of water.

All else being equal, the productivity of a region depends upon the amount of land area in production. The land that once supported the plants that fed deer, mice,

Exhibit 4

and birds will be used for the plant site, storage areas, settling ponds, roads, mining, and so on, and will no longer support the living organisms. Therefore, the simple destruction of habitat for other uses will decrease the biota.

The presence of man-made structures directly affects the flora and fauna. Especially to birds, these structures, including transmission lines, are physical hazards that may increase mortality rates significantly. The structures may also provide nesting sites or other accommodations for some species such as the common pigeon. The overall effect of the structures on the native species will probably be to reduce their numbers.

Although the impacts of power lines on game birds and hunting are not well known, one recent study shed some light on the subject.[15]

During the study, in Wisconsin, it was observed that Canada geese in normal flight never flew under power lines. No geese were known to be shot by hunters within one-quarter mile of powerlines. In spring and non-hunting periods in the fall, geese landed within one-fourth mile of powerlines, fed near them, and walked under them, suggesting that the lines hinder goose hunting in season.

Ducks were less wary of powerlines, but the wariness varied with species. Duck shooting success on a private march declined about two-thirds after a powerline crossed the area, and shooting was limited to local birds early in the season. It thus would seem that hunting might be affected if the powerlines from Colstrip were to pass through or near grainfields along the Yellowstone River. No adequate assessment can be made of environmental impact caused by powerlines and pipelines until their actual routes are known.

The noise and pollution from the proposed facility will alter the ecosystem, affecting the flora and fauna. The emissions from the plant will put a stress on some plants which may kill them or reduce their ability to compete with other species. Certain plants may be completely replaced. If such plants are essential to the survival of some animal species, a very significant change in community structure could take

Exhibit 4

place. Likewise, certain pollutants may be very toxic to some species or may interfere with their reproduction, again leading to a major change in community structure. Some other species may be favored by these changes.

The increased activity of vehicular traffic, hikers, hunters, dogs and cats will have a damaging effect upon the flora and fauna in most cases. Greater numbers of people living and working in the Colstrip area will increase the contact between man and the natural ecosystem. This increased activity will be a direct result of the proposed power plant.

The aquatic ecosystems in the area, including the Yellowstone River, will be altered in a number of ways. The diversion of water for the proposed plant will decrease the flow in the Yellowstone. The water quality will also be changed as stack emissions get into the water, and as towns increase in size producing more sewage and urban-type runoff. It is impossible to quantify these changes or predict the major changes in such activities as sport fishing.

It is impossible to determine the impact of water appropriation from the Yellowstone River until the actual volume to be used is known. The applicant has told the state that the pipeline will be 22 to 26 inches in diameter. However, documents dated December 22, 1970, and filed in the Rosebud County Courthouse in Forsyth, record that the applicant has appropriated 250 cubic feet a second, to be transported through a 60-inch pipeline. The applicant indicates the large appropriation was made because at that time it was uncertain how much water was to be needed.

As noted earlier, information on the pipeline is unavailable.

If the applicant were to use the full 250 cfs appropriated, it could have a serious effect on the Yellowstone River below the outlet, as noted in Table 10.

It should be noted that figures supplied by the Environmental Defense Fund show that 250 cfs should supply a sustained generation capacity of 9,875 megawatts. For comparison, a 24-inch pipe supplying 40.1 cfs would sustain generation of up to 1,590 megawatts. Although the applicant has disclosed no plans for more than 700

Exhibit 4

megawatts of generating capacity at Colstrip, officials of the Bonneville Power Administration have stated publicly that the applicant is considering construction of two 700-megawatt generators in addition to the development now proposed. The officials said the two additional plants would be expected to go on line in September, 1978, and September, 1979. To get the plants operable by that time, it was indicated, a decision to build would be necessary early in 1973. Such construction would require more water than could be transported in a 26-inch line.

Under Montana law, any water appropriated but not used may be appropriated by another user. Thus, if the applicant does not use the full 250 cfs, it may be appropriated by another consumer.

Considerable interest has been expressed regarding the possible construction of units three and four. The applicant has indicated that if the decision is made to build these additional units, reapplication would be made to the state, considering the increased scope of the operation.

TABLE 10

STATION	DRAINAGE AREA, MI^2	MAX. FLOW cfs	MIN. FLOW cfs	AVG. FLOW cfs
Yellowstone at Billings	11,795	66,100	430	6,754
Bighorn at Bighorn	22,885	26,200	275	3,756
Tongue at Miles City	5,379	13,300	0	405
Yellowstone at Miles City	48,253	96,300	996	11,140
Powder near Locate	13,194	31,000	0	600
Yellowstone near Sidney	69,103	159,000	470	12,910

Records show that between 1931 and 1965 the lowest daily flows of the Yellowstone River at Miles City averaged 1900 cfs. During these low water periods the flow of the Tongue River and Rosebud Creek is nil or nearly so. Therefore, low flows at Forsyth also should average 1900 cfs. Thus, 250 cfs at Forsyth would represent about one-eighth of the river's total flow at low flow in an average year.

In its comments on the draft statement, the Environmental Quality Council commented on consumption of water from the River as follows:

Exhibit 4

"Assuming utilization of the total appropriation of 250 cfs, proportionate use of Yellowstone River water would range from 11% to 25% at minimum discharge levels and 2.2% of the 43-year average discharge. For those who would contend that this is an unrealistic figure because appropriations are usually far above what is actually diverted and used, the Appraisal Report on Montana-Wyoming Aqueducts lists approximately 2,350 cfs (1,700,000 acre-feet per year) of Yellowstone River water subject to development as industrial water supplies and a recent newspaper editorial written by a Bureau of Reclamation official indicates that in normal years the flow of the Yellowstone would be reduced one-third and in a dry year the flow would be reduced about one-half as a result of water diversion for industrial use.[29]

"The diversion of water of the magnitude discussed in the paragraph above would have effects on the water quality of the Yellowstone River in the following areas:

1. Temperature. Loss of water volume and buffering capacity would result in more erratic temperature fluctuations, higher temperature maxima and more prolonged periods of freezing, thus affecting:

a. life histories of fish, invertebrates and aquatic plants.
b. growth and reproductive rates of preferred and undesirable fish species, possibly giving the latter a competitive advantage and resulting in changes in
c. relative abundance of preferred and undesirable fish species.
d. growth rates of aquatic plants, including algae; possibly enhancing seasonal production resulting in nuisance blooms and taste and odor problems.
e. diversity of the aquatic community.

2. Concentration of Pollutants. Most water quality management plans are based on the dilution effect afforded by the receiving waters. Once a substantial volume of dilution water is removed polluters may find themselves in a position of noncompliance with existing water quality criteria. Parameters, the concentrations or levels of which may be affected, include:

a. coliforms.
b. biochemical oxygen demand (BOD) and dissolved oxygen.
c. pH
d. turbidity.
e. temperature.
f. residues.
g. sediment or settleable solids.
h. toxic substances (pesticides and heavy metals).

In the extreme case, one or any number of these factors may increase (or decrease) in value or concentration to the point where the tolerance level of fish and bottom organisms is exceeded and community diversity is thereby reduced.

3. Concentration of Nutrients. Nutrients, particularly phosphorus, nitrogen and carbon, are critical to growth of algae and other plants which form the base of the aquatic food chain. Only slight increases

Exhibit 4

in the usable concentrations of these three strategic elements, alone or in combination, are often enough to trigger massive algal growths or blooms which could degrade the water aesthetically by causing taste and odor problems and visual unsightliness. The Yellowstone River, however, is not subject to this type of problem except where it or its confluent the Missouri may be impounded.

These are three areas where water quality would be affected by diversion away from the river. These are merely the types of problems that may arise; statements on their extent would be speculation at this time. The severity of the impact would be determined by the magnitude and timing of the withdrawal. Critical parameters should be monitored over a period of years to detect undesirable changes as development progresses and more water is appropriated, withdrawn and consumed."

The Ecological Consulting Service of Helena under contract to the applicant, is studying the possible effects.

Adequacy of air pollution standards

The State in its Ambient Air Quality Standards wrote

"The air quality standards listed describe a level of air quality designed to protect people from adverse effects of air pollution, and they are intended further to promote maximum comfort and enjoyment in the use of property consistent with economic and social well being of the community."

At this time, the State sees no reason to doubt the adequacy of the standards.

The EPA defines its primary standard as adequate to protect the public health to a sufficient degree. The EPA secondary standard is calculated to protect the public welfare from any known or anticipated adverse effects from pollution.

The EPA is believed to be considering new standards, and should these go into effect, provisions are available for backfitting additional pollution control equipment on the Colstrip plant, should it fall under the new standard.

For example, additional SO_2 removal could be accomplished by adding stages to the venturi scrubbers.

Social and economic impacts

The human dimension of the proposed Colstrip development is perhaps the most difficult to assess adequately. The economic aspects are somewhat more clear cut and some of the benefits of increased coal production at Colstrip can be predicted. Some of these follow:

Exhibit 4

Tax Returns

Under present tax laws, coal using operations are subject to the following kinds of taxes and fees:

a. Strip Coal Mines License Tax--paid quarterly to the state, based on gross value of tonnage mined, and heat content of the coal. The first 5,000 tons are exempt from taxation, and a credit of up to one cent per ton for land reclamation may be claimed, or else one-half the cost of reclamation, whichever is lower.

b. Corporation License--paid annually to the state, based on 5.75 percent of all net income earned in the state, with a minimum of $50.

c. Net Proceeds--paid to the county, based on tonnage mined. Net proceeds of mines and mining claims fall in Class 1 of taxable property, taxed at 100 percent of "full and true" value. So, although it has the appearance of an advalorem property tax, this is in fact a tax on production.

d. Property, both personal and general (land and improvements)--paid to the county. At the discretion of the Legislature and with the approval of the electorate, a statewide property tax of up to 2 mills paid to the state may also be levied.

Coal-using companies, power generating and distributing firms are subject to the Electrical Energy Producers' License Tax, amounting to 1.438 percent of the gross value of electrical sales, and to corporate income taxes as well as property levies. No taxes peculiar to coal-conversion companies have been enacted.

Rates at which these taxes are levied are based on amount of capital investment, volume and type of coal mined, or net income from operations. From partial figures on coal company operation, it appears that all taxes (not including royalty payments) paid to county and state are currently averaging about 18 cents per ton mined. The three companies on the tax rolls for the calendar year 1971 paid to the state and local governments 1 1/4 million dollars on 7 million tons mined.

For newer generation-plus-mining operations, payrolls are reported to average about $10,000 per employee, with this income subject to state income taxes, local property and special taxes, gasoline taxes, and licenses and fees.

"Value added by manufacture" is a rough measure of the relative tax-yielding character of an industry. But the added value may be due to high capital investment in machinery and equipment, subject to property taxes; or to high investment in personnel

Exhibit 4

and payrolls, subject to income and other taxes. It cannot be assumed, of course, that increased tax returns will lead inevitably to lower taxes per capita. Rosebud County however, has already felt a sharp increase in tax returns per capita as a result of coal-based operations.

Employment

Jobs and population increases from coal development will depend on the number and kinds of enterprises that are established. From present evidence, the number of jobs created per million tons of coal extracted per year are about as follows:

Mining only	10 to 20, depending on scale and efficiency of operations.
Power Generation	40

Multipliers

The relationship between numbers of jobs and the probable general population is calculated by using "multipliers." One of these described the numbers of service and professional occupations ("derivative" jobs) that appear in an economy as a result of a given number of new primary or basic jobs. In Montana, this relationship was derived in the Montana Economic Study by the University of Montana's Bureau of Business and Economic Research in 1970, on the basis of statewide historical figures up to 1969; and the multiplier was 2.7. This meant that in general 1.7 derivative employment positions have developed for every basic job -- defined as jobs based on products or services for export, and therefore creating income to the community or state from "outside." The multiplier was not worked out for different portions of the state, however, and a study of recently acquired figures giving data by counties shows indication that this multiplier is probably lower in the eastern counties, many of them characterized by population decrease and economic decline for decades. Another multiplier is the average size of family or household -- or more accurately, the number of persons supported by each of the income-producing jobs. Use of the average household size (3.1 persons in 1970) to estimate population would give an inflated projection, because it assumes each of the jobs would be filled by a separate breadwinner and would

Exhibit 4

represent a different household. The statewide ratio of population to jobs in 1970 was about 2.8, but this ratio obscures the "true" relationship because it includes a sizeable unemployment figure, which would not be characteristic of an area with expanding job opportunities and increasing employment.

Population increase would be inevitable if coal mining increases and increased numbers of jobs and people mean social impacts of various kinds. But it must be remembered that the eastern counties have already been undergoing considerable social impact from population and employment changes during the past decades. Although not all the counties have been decreasing in total numbers of people, all but one suffered net out-migration during the past decade, and all but one are subject to an "employment-gap" amounting to between 6 and 29 percent of total 1970 employment, and averaging 15 percent for the 14 counties. This employment-gap claculation was used in the Montana Economic Study to describe the amount of additional employment growth that would have been required to prevent out-migration of the labor force. It assumes that stopping net out-migration would have required a growth in employment sufficient to absorb the entire "natural" growth of the labor force (which depends on normal population growth rates in the area) and in addition reduce the unemployment rate to the 1960 national average, which was 5.1 percent and has been both higher and lower in the interim. By this kind of calculation the "employment-gap" still to be filled in 1970 amounted to at least 4,400 jobs in the 14 counties, and probably more.

The town planners hired by the applicant predicted that the population of Colstrip would reach a maximum of 1866 in late 1974, declining in 1976 to a permanent population of 1781.

Not all of this population would work directly for the company, and many or most of them would be the non-working dependents of the workers. As shown in Table 11 the payroll for construction, mining, and operation employees would peak in December, 1974, at $2,493,000 per month declining gradually to $410,000 per month after October, 1976.

based on:

Project 1972 costs - no escalation
Includes payroll estimate for construction, operation, and mining labor.

Exhibit 4

It is uncertain whether the tax benefits from the project would adequately offset the social problems that might ensue.

Few predictions can be made about the needs of the increased population. The State Department of Intergovernmental Relations believes the increased needs can be met with the increased revenues.

The Montana Board of Crime Control has developed a concept of what would be needed to enforce the law in the Colstrip area, following the influx of population. Rosebud County will require a new deputy sheriff, deputy probation officer, and secretary. A patrol car and other law enforcement equipment would bring the total estimated initial cost increase in the area to $40,579.69.

A 25-bed hospital under construction in Forsyth is considered adequate for the increased population.

As noted above, the police protection is furnished by the county. Fire protection is the responsibility of the Western Energy Company. Ken R. White recommended construction of a fire station in Colstrip.

Two churches also were recommended. Library service will be furnished through a bookmobile from Billings.

Substantial expansion of housing was recommended, as noted in the summary of the plan furnished in the appendix.

Heavy impact will be felt in the schools at Colstrip. Currently there are nine teachers and 141 students in the Colstrip elementary school, and eight teachers and 128 students in the high school. The superintendent of the Colstrip schools indicates that mobile units will be brought in as the need is felt. Initially, it is planned to add two classrooms, a library, a cloakroom, and a lavatory, to accommodate 55 to 60 students.

Much of the housing to be developed around Colstrip will be trailer units. The Western Energy Company has requested that the state approve a 68 unit mobile home park

Exhibit 4

on the south side of Colstrip. There should be no water pollution potential from the site, as it is proposed to connect to the town sewage system. The municipal water supply also would be utilized. A considerable impact may result from the amount of grading necessary.

It is estimated that 3000 cubic yards of site grading excavation will be required, along with 16,000 yards of site grading borrow material and 9000 cubic yards of topsoil excavation. Storage and replacement of the topsoil is required. Roads in the area will be surfaced, and all disturbed areas not otherwise stabilized will be planted with grass. Drainage and surface runoff will be controlled with landscaping and culverts.

The increase of population in the area will contribute to the impacts expected from the total population increase expected, as noted earlier.

Whether this area is maintained as an attractive housing site will depend on the trend of employment at Colstrip. If as predicted, the population levels off at almost 1800 persons, the area might escape the type of blight that often afflicts temporary housing areas.

Social impacts will be caused by the gradual change of lifestyles from agricultural to industrial. Although the loss of agricultural land is regrettable, the economic impacts may offset the loss. For example, ranch workers, many of them married and with families, ordinarily earn between $300 and $500 per month. With greater job opportunities resulting from coal development, these same men may earn $10,000 a year or more.

The quality of the overall development at Colstrip will depend in large part upon how diligently the applicant follows the town plan. The applicant asserts that architects have already been hired to implement the plan, which will be modified and updated to cope with changing situations.

Some impact also will be felt as subdivisions develop near the town, and as more families buy small acreages of land away from town. Some impacts already are felt on the Northern Cheyenne Indian Reservation from non-Indian workers living on tribal land, and purchasing supplies in Lame Deer. The Northern Cheyenne Indians have mixed feelings about the project. Some believe that the development will bring work to tribal members

Exhibit 4

and increase the standard of living, while others believe that increased contacts between non-Indians and Indians will be detrimental to the tribe.

Plans to Lessen Overall Impact

Efforts by the applicant to assess and minimize the environmental impact of the proposed plant include the financing of a number of special environmental studies, as follows:

1. Archaeological survey by the University of Montana. Completed, results in Appendix.

2. Study by Montana State University of air pollution effects on native vegetation, animals, soils in the vicinity of Colstrip. Preliminary survey results in Appendix.

3. Meteorological data collection and climatalogical interpretation of local weather pattern by MSU. One year's preliminary data used in diffusion modeling. Summary included in statement.

4. Air quality monitoring by the applicant.

5. Town planning for Colstrip growth by the Ken R. White Company, Denver, Colorado. Plan completed, summary in Appendix.

6. Wildlife habitat utilization in the vicinity of the generating station by the Ecological Consulting Service, Helena. In progress, preliminary survey results in the Appendix.

7. Determination of the presence of trace elements in the coal, and their disposition through combustion, by West Associates. No data yet.

All studies performed by MSU for the applicant will be available to persons with a "need to know," according to a spokesman for MSU.

Exhibit 4

IV. ADVERSE ENVIRONMENTAL EFFECT WHICH CANNOT BE AVOIDED SHOULD THE PROPOSED BE IMPLEMENTED

Exhibit 4

Exhibit 4

IV. ADVERSE ENVIRONMENTAL EFFECTS WHICH CANNOT BE AVOIDED SHOULD THE PROPOSAL BE IMPLEMENTED

There are a number of basic operations and effects that are inherent in a coal-fired power plant of the kind proposed. The impacts of these operations and effects cannot be avoided. The following group of effects is considered unavoidable, should the plant be built:

1. The consumption of about 90 million tons of coal in 30 years.
2. The consumption of 4.2×10^9 gallons of water per year.
3. Some air pollution--the amount of pollutants can be reduced, but not to zero.
4. Occupation of land by plant, mine, aqueduct, transmission lines, and human habitation space.
5. The adverse effects of increased population in Colstrip vicinity.
6. Change of life styles and social values as society is transformed from agrarian to industrial.
7. Aesthetic impact of facilities.

Exhibit 4

V. ALTERNATIVES

Montana Power Company and Puget Sound Power and Light Company have decided to build a coal-fired electrical generating plant at Colstrip if given permission to do so. The Department of Health and Environmental Sciences will decide to issue or deny the permit for construction. The decisions made by all parties concerned are choices of a wide range of possible alternative actions. The proposed actions of the companies involved, are alternatives which they presumably believe will be in their best interests. Whether or not the company's chosen actions are in the best interests of the people of Montana remains to be seen. What alternatives exist to the building of this plant other than proposed?

The alternatives that may be considered, include both ones realistically applying to the proposed plant and ones involving this plant's role in the national energy configuration over a longer period of time. The kind of cooling, for instance, which may be applied to this plant, is a real alternative which can be considered at this time. Building a magnetohydrodynamics (MHD) plant instead, is not a real alternative for this plant at this time. MHD is a possible alternative to the conventional type of power plant at some point in the future. The dividing line between these types of alternatives is arbitrary.

Real Alternatives to the Proposed Plant

The first real alternative which must be considered is that of not building a power plant. The decision to build the plant is based on meeting the "demand." "Demand" is a word that is heard a lot these days and perhaps should be discussed a bit further at this time. Demand, when discussing the use of electricity, is that amount of energy that the customers will use if it is available in the wires. To the consumer, the end of the wire is, practically speaking, an unlimited source if instant energy. As long as the voltage in the line is at the prescribed level, the consumer can extract all the

Exhibit 4

energy he needs at the moment. He cannot fill bushel measures with it to save for shortages, but neither is he limited in its use--that is until a brownout or total failure occurs. As long as the voltage is maintained in the line, the consumption of electrical energy is independent of the generating capacity at the power plant. Increasing generating capacity alone will not sell more power. However, if inadequate generating capacity exists, brownouts or failures will occur. Since brownouts have not occurred in Montana in the recent past, the growth of the demand is independent of the power companies except that attributable to their extensive advertising. (Even though Montana Power Company claims that their advertising does not increase the demand, this claim must be seriously doubted due to the large advertising budget of the company. They claim that the yard lights which they have promoted for years only serve to even the load during the 24-hour day.[20] Again, this argument can be questioned since such devices as timers on electric water heaters, which are used by other utility companies across the nation, are neither promoted nor available from Montana Power Company. Such timers would be more effective in balancing the load than the increased use of yard lights.) The decision to build a new power plant is a decision to continue to meet the demand. Unfortunately, if the demand on a particular line is not met, all of the users suffer the brownout--there are no preferred or established customers if they are supplied by the same wire.

The applicant has based their decision to construct on projected demands. According to the Bonneville Power Administration, (BPA), the rate of electrical energy use in Montana increases about five percent per year. Elsewhere, the growth rate is about seven percent, which causes a doubling of demand every ten years.

Figures from the National Power Survey, cited by the applicant, projected a demand increase from 1,460 mw in 1970 to 2,590 mw in 1980, in the area comprising Butte, Anaconda, Billings, Helena, Great Falls, Kalispell, and Missoula. The projection for 1990 in the same area is 4,700 mw. These power levels are peak loads, and are not entirely supplied by the applicant.

Exhibit 4

The applicant asserts it has had a deficiency in self-generated power in recent years. The applicant claims its self-generated resources in January, 1973, totaled 768 mw. An additional 263 mw were received from other utility sources.

In the opinion of the applicant, many of these other sources no longer will be available in 1975. The predicted 1975 peak load in the applicant's supply area is 1098 mw. The applicant asserts that brownouts could occur in 1975 if the proposed plants were not built, because the 768 mw capacity could not meet the predicted 1098 peak load.

A variety of new loads is predicted to contribute to the increased power demand. For example, U. S. Plywood and Champion International Paper is expected to need an unspecified but "significant" increase in power for expanded activities in about 1974. The Anaconda Company will need 25 mw for its new Anaconda smelter by 1975, the applicant states.

Further information from the applicant indicates that residential usage of electricity accounted for only about 20 percent of the total MPC output in 1972.

The applicant continues:

> "Several signs of growth, such as population growth, rise in the living standard, rise in recreation and tourism and employment for Montana in the decade 1970-1980, are evidence of the continued growing need for electrical energy in Montana for both residential and industrial use.
>
> "Secondly, in addition to the projection of more people and industry in Montana which will require more energy, the present market of electric energy is not exhausted. For example, only 75 percent of Montana's potential residential customers have electric ranges, only 60 percent have electric dryers, only 14 percent have outdoor lights, and only 9 percent have air conditioning. The percentage of customer growth has been the highest in history in the past two years for the Montana Power Company and is expected to continue."

One source of increased electrical demand is the farmer, who has found it feasible to place more acres under cultivation with the use of electrical sprinkler irrigation. The following is the annual added usage for irrigation purposes, from Montana Power Company information:

Exhibit 4

Year	Horsepower Added
1961	1380
1962	1333
1963	1622
1964	2163
1965	2042
1966	1643
1967	2767
1968	2582
1969	2081
1970	2743
1971	4643
1972	4292

It is predicted that the amount of energy used for environmental improvement on a national basis will increase from about two percent of total energy consumption in 1970 to four or five percent in the period 1970-1985.

The applicant indicates that sewage and water treatment facilities in Billings and Great Falls each will use enough electricity to serve an average Montana town with a population of 10,000.

Further information from the applicant notes that the Humble Oil Company in Billings has a water treatment system using four 50 HP electric motors on large aerators in the ameliorating process.

> "Great Western Sugar Company in Billings is constructing a new sewage treatment facility that will require 600 to 700 HP in electrical load. Furthermore, the air pollution equipment to be installed in the Colstrip plant will use approximately 25 mw. . .approximately 1/30 of the total electricity now generated by the Montana Power Company."

Although the applicant states that only 1,483 homes are electrically heated in the MPC service area, peak loads occur in the winter. The stated reason for this is

> "because the temperature is colder and the days are shorter which results in greater uses of electricity. For example, with shorter days more lighting is required. With shorter days and colder weather there is a tendency for people to be indoors and use more electricity for lighting, clothes drying, hot water and heating. In addition to electric heat, forced air and natural gas heating systems use electric thermostats, fans and blowers."

Montana Power Company peak loads are illustrated in Figures 10 and 11 and Table 12.

As noted, at least half the power generated will be delivered to the Northwest Power Pool, which serves Washington, Oregon, Idaho, western Montana, and other areas in the western U. S. through inter-ties with other pools. The BPA has testified at length on the probable need for power increases in the area served by the Northwest Power Pool.

The BPA indicates that the aluminum industry is the single largest power consumer in the Northwest. In 1970, the industry used about 21 billion kilowatt hours of electricity in the region. Individual plant use varied from 1.25 billion kwh to 3.5 billion kwh.[35]

The second largest industrial use is paper manufacturing with 45 pulp and paper plants in the Northwest. No specific data was immediately available on power usage by these plants, although some individual plants are known to demand almost 100 mw. The BPA estimates that pulp and paper plants account for 15 percent of the industrial use of electrical energy in the region. The third largest industrial user is the forest products industry, using over three billion kwh annually.

The following table (Table 13) from the BPA shows electric energy use by the West Group Area of the Northwest Power Pool for calendar 1970 and the percent of total electric energy use for each class compared to these same percentages for the U. S.

Exhibit 4

The West Group area includes Washington, Oregon, Idaho, and the portion of Montana west of the Continental Divide.

Table 14 and Table 15 further illustrate power demand projections in the Northwest.

According to BPA, a significant portion of the energy to be needed in the Northwest will be used for environmental clean up. For example, one pulp mill recently requested 7.5 mw for pollution control. If all 45 pulp plants required a similar amount of power, the demand would be considerable. BPA apparently does not agree with the applicant about the potential for large energy demand by sewage treatment, solid waste disposal and recycling processes. According to the BPA, such operations are "not large consumers of electric power."

Electrical heating units in the power pool region used about nine billion kwh in 1970 or 30 percent of the total residential electric energy use, according to the BPA. Usage of electric heat is expected to triple in the next 20 years "as shortages of fossil fuels and concern for a clean environment in the home and in urban areas accelerate demand."

No estimate was available as to possible increases in electric heating in Montana. However, MPC Executive Vice-President J. A. McElwain stated before the Board of Health on January 12, 1973, that his company does not advertise electric heat because "it's just not practical in Montana."

One BPA official has written a paper on the needs of the Northwest for more power. After detailing many reasons for the need, he summarized:

> "We are, in other words, building an affluent society (provided, of course, there is enough power for industry and commerce to create the necessary jobs and income) which will make it possible for the average consumer not only to purchase new homes and appliances, but to replace older appliances with newer ones which generally require more electricity." [9]

If an ever increasing demand for electricity is to be met in Montana, more generating capacity must be built. The no-build alternative means either the demand will not be met or the growth of the demand must be curbed. To stop the growth of the demand by 1975 would require a number of imaginative, bold, and unpopular steps by the

Exhibit 4

State, or, even less likely, attitude changes by society. Although it is felt by some that the growth of this demand must and will be slowed in the future, its occurrence in Montana within two years seems highly unlikely. The quickest manner in which this slowing could be brought about would be in rationing or taxing the price of power to limit the growth of the use of electricity. The increased cost would tend to cause customers to shift to other sources of energy or do without.[24] The political climate in Montana at this time places real limits on how far the State could proceed in this direction.

It can, therefore, be concluded that the no-build alternative is not feasible for this particular power plant.

Another real alternative involves the method of condensing the steam. Several methods can be used for this function, but since there is no large stream of water near the plant, once-through cooling can be ruled out as a real alternative. Even though the company has elected to install wet cooling towers, dry cooling is a possible choice that may be in the best interests of Montana. The State does not have adequate data to determine which is better at this time. The company claims that dry cooling is less efficient than wet cooling and will result in greater use of coal for the same power. This claim may or may not be true, but even if true, society may decide at some future time that the water is more valuable than the extra coal that would be burned. Another claim for wet cooling is that dry cooling is much more expensive; however, there are indications that if many power plants are built in Montana and Wyoming, it will be cheaper for society at large to insist upon dry cooling.[29] The ultimate decision on which method would be best for Montana would require extensive study. These studies have not been carried out to date, because until March, 1973, the State has not had the authority to affect any decisions on this subject and it still cannot affect decisions on this proposed plant.

The proposed plant will employ a venturi scrubber to remove particulate matter and gases from the stack effluent. Alternative collection devices exist and are in use

Exhibit 4

in other power plants. The most widely applied air pollution control unit for power plants in recent years is the electrostatic precipitator (ESP). The Corette plant in Billings, for instance, uses an ESP. Although ESP's can remove up to 99.5 percent of the particulate matter, they cannot remove gases. The venturi scrubber will remove a significant amount of SO_2 and gaseous fluorides which would otherwise be emitted into the atmosphere. This Department believes that the best available control technology is planned for the Colstrip plant.

The location and size of the proposed plant is also subject to alternatives. The State does not have the authority to insist upon possible changes in these factors for this plant (future plants will come under the jurisdiction of the newly enacted siting authority). As shown above, the size of the plant by itself will not change consumption patterns unless it is inadequate. The size of the plant is then a moot point. As to the best location, no study by the state has been done on this aspect. There are many places in the state that would be a worse location for the plant, but whether better locations exist is not known. The location of future plants will be considered by the State.

The demand for electrical power could possibly be met by a generating facility utilizing some method other than a conventional coal-fired boiler. Other forms of fossil fuel are more limited than coal and would not be acceptable from several environmental aspects. Nuclear plants require a long lead time for design and construction. Substituting a fission plant for coal is not feasible if the 1975 demand is to be met; therefore, is not an acceptable alternative to this particular plant.

This discussion on "real" alternatives is not meant as an excuse to build the plant as proposed. With the authority that the Department has over this particular plant, the alternatives which really exist are voluntary ones. Decisions on these alternatives will not be entirely up to the company for future power plants in Montana.

Exhibit 4

Long Term Alternatives

Many people are concerned about the exponential growth of electrical demand in the U. S. There exists a very definite limit (measured in decades) to the extent that this demand can grow and be met with fossil fuel. Effort should be expended to reduce the energy demand and to find alternate ways of generating power other than the burning of fossil fuels. These alternatives are longer term than those which are real for the proposed Colstrip plant. The reader is referred to Mr. Albert Melcher's discussion of alternatives in the Appendix.

Exhibit 4

VI. RELATIONSHIP BETWEEN LOCAL SHORT TERM USES OF MAN'S ENVIRONMENT AND LONG TERM EFFECTS

Our society's dependence upon electrical energy is growing rapidly. A form of energy developed in less than a century is now used in so many ways in the domestic, industrial, and commercial sectors of our society that our way of life is dependent upon it. The technological and economic changes of this century have been so dependent upon electricity that this form of energy is considered by many as essential to civilization. Others argue that civilizations have existed for many times as long as has electrical energy production and there is little indication that this society is more civilized than ones gone before. Even in existing societies, it is contended that there is no relationship between electrical power consumption and degree of civilization.

The rapid growth of electrical energy consumption in the U. S. at this time is an indication of our dependence on this commodity. This "demand" for electrical energy, and many question whether this is a real or artificially stimulated demand, is presently being met largely by the consumption of non-renewable resources: coal, oil, and gas. This "demand" is presently growing in such a manner that consumption doubles roughly every ten years. This kind of growth is referred to as exponential. At this rate of growth, the "demand" in just three decades will be eight times its present value. Because coal is being used to produce much of this energy, the consumption of this non-renewable resource is also growing exponentially. Although there are large quantities of coal still in the earth, there is considerably less than has been expressed by some. Global reserves are estimated to be 5×10^{12} tons or a 2300-year supply at current rates of consumption. However, at a growth rate of 4.1 percent annually (much less than the growth rate of electrical "demand") there is only a 111-year supply. Even if there is actually five times as much coal as estimated, the supply is only 150 years at a growth rate of 4.1 percent. In addition, the U. S. has about 32 percent of the world supply but presently consumes 44 percent of the world production. (Limits to Growth, Meadows, 1972, Universe Books, New York.) Therefore, if the

Exhibit 4

electrical "demand" continues to grow at its present rate and this growth is met largely by the conversion of coal, the coal reserves in the U. S. will be greatly diminished in a few decades. The coal, once consumed in a power plant, is lost forever. Future uses of the coal, whether to generate power or as a source of chemicals for production of some other commodity, are denied. The future needs of the coal may be more urgent than our present needs for electricity.

The proposed Colstrip generating plant will not consume the reserves in Montana by itself, but it cannot be divorced from the overall energy situation of the country. (The expressed purpose of the plant makes this point clear.) At present, coal is being removed from the area for power production outside of the Fort Union Region and more power plants are being planned within the Region.

Depletion of coal as a resource is not the only long term consideration involved here. An economy based on the exploitation of the coal is developed in the coal fields themselves, as well as where the electrical energy is being consumed. The short term gains to the Colstrip area are made known by the interests involved in building the plant and mining the coal. Jobs are created and money enters the local economy from these jobs. As long as the coal is mined and the power is generated, the flow of money through the community is assured. When the coal is exhausted, or its use for production of electricity becomes obsolete, the economy and way of life dependent upon the exploitation of the coal will suffer. Many feel that this consequence is inevitable; that only its magnitude and timing are in question. Improper reclamation of the land may destroy the original economic base of the region: the land used for agriculture. Numerous examples of boom and bust cycles can be cited. There is little evidence that this sort of thing will not happen in the Fort Union Region.

At the other end of the transmission lines, is a society and economy becoming more and more dependent upon electricity. Not only is the per capita use of electrical energy increasing, but the number of persons kept employed, warmed, and fed by this energy is increasing. Each ton of coal that is used to meet the increased "demand"

Exhibit 4

of electrical energy is increasing the entire society's economic and physical dependence upon electricity. A civil disturbance or war or other sudden interruption of the supply of electricity would be catastrophic. Likewise, a sharp rise in the cost of electricity would put a strain on the economy through businesses, manufacturing, and domestic use. This situation is true today but will be more critical as time goes by and our society becomes more and more dependent upon this energy.

The possible local destruction and regional degradation of the ecosystem by the proposed Colstrip plant also has long term implications. Land use changes adversely affecting food production, modification or loss of recreational areas for present and future generations, and changes in natural species may be more significant to our descendants than our use of electricity over the next several decades. Residents of the area will be subjected to changes in social and psychological pressures from this industrial economy and life style, as the change is made from an agricultural base to a more industrial one. Future residents may encounter the reverse situation; that is, adapting to an agrarian life style should the industrial form be removed or altered.

On the more positive side, one can speculate that both short term uses and long term uses will be beneficial. The short term, while the coal supply lasts and through the life of plant operation, will see increased employment in the Colstrip and Fort Union area, and at the receiving end of the electricity. The tax base for the communities will also increase. Over a longer period, the increased employment resulting from the short term energy use may continue indefinitely, even though coal is no longer available for power generation. Alternate energy sources will probably emerge as economics dictate their practicality. It is even possible, although not probable, that some of these sources may locate in the Colstrip-Fort Union Region, where water supply and transmission systems will already exist. On reclamation of strip mined land, and possibly obsolete power plant sites, it would appear that society's increasing environmental concern will move to disallow any but the most advanced reclamation methods for the time. It is not inconcievable that reclaimed land can be returned to its

Exhibit 4

former levels of productivity. Still on the positive, it can be argued that man continues to accept new challenges as they arise and often prevails, minimizing negative consequences. Few dispute that electricity benefits society, and that a major reduction in per capita energy available would be detrimental. Evaluation of these and other potential consequences, be they boon or bane, is nearly impossible. The factual information necessary to make such determinations is, at best, scarce and few people are willing to make judgments of the relative desirabilities of such alternatives for the future.

The relationship between the short term effects and long term effects is one of space and time. It is so much easier to plan for the short term than for the long term. The effects that occur in the long term are seldom planned or taken into consideration in planning. The long term effects, both good and bad, of the Colstrip plant will be accidents, in that they are not planned. One's concern is greatest for things and persons closest to him in space and time. As situations are removed in time (future) or involve a larger portion of the world, a person spends less time and energy thinking about them. For instance, a person is much more concerned with his family over the next few years than with the nation over the next hundred years. (Limits to Growth, op. cit.) Actions based upon these different levels of concern are often contradictory. It is also much easier to accept decisions that have more personal and quicker results than ones less personal and farther removed in time. It is, therefore, easier to decide in favor of a power plant that will prevent a small power shortage in one's own town in four years than to be concerned with the fate of a large portion of the United States society fifty years from now. Even though some very serious problems for mankind seem to loom in the future if he continues on his present course, he is reluctant to give up his immediate comforts. This concept is well illustrated by our attitude towards energy in this society. When evaluated at some future date, the proposed Colstrip plant may prove to have been very efficient at solving one immediate problem, but in doing so having created other problems of much greater scope and duration.

Exhibit 4

VII. IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS OF NATURAL AND ECONOMIC RESOURCES

The consumption of a non-renewable resource is an irreversible commitment. The burning of coal in the proposed power plant would be the major consumption of a non-renewable resource. Approximately 90 million tons will be burned in 30 years, which represents the coal under nearly 2000 acres if present mining methods are used.

Since this coal will be mined by stripping, 2000 acres of land will be disturbed which will put it out of production at least temporarily. If adequate reclamation is not possible, the 2000 acres of land will be permanently degraded.

There are also some of the materials that will be used in the construction of the plant itself plus the aqueduct and transmission lines. Metals and other materials that can be recycled do not fall into this category.

Exhibit 4

VIII. RESPONSE TO THE DRAFT STATEMENT

Exhibit 4

Exhibit 4

VIII. RESPONSE TO THE DRAFT STATEMENT

The Department of Health and Environmental Sciences has received over 3000 responses concerning the Colstrip power plant and general coal development since publication of the draft statement in October. Included in these responses were specific comments on the impact statement. The mail consisted of letters, postcards, petitions for and against development, and coupons from the Billings Gazette which express disfavor with the development.

Approximately 95 percent of the responses opposed development of the plant and coal mining operations. A breakdown of the mail as of January 4, 1973, concerning the proposed plant and coal development follows:

For the plant or coal development:	
Letters	73
Postcards	3
Signatures on Petitions	54
Total	130

Against the plant or coal development:	
Letters	1162
Postcards	55
Coupons	300
Signatures on Petitions	1350
Total	2867

A rush of correspondence arrived in late November and early December, which was probably precipitated by several articles in the Billings Gazette, including a front page editorial. Very few letters were received after January 4, 1973, and their change on the total figures presented above would be very minor.

Exhibit 4

Ranchers, doctors, lawyers, housewives, students, small town and urban dwellers, businessmen, retired persons and many more have written. Most of the writers were from eastern Montana, but included residents from other parts of this state and other states.

The fears most often expressed were:

1. Strip mining will proceed with little, if any, adequate reclamation of the land.
2. Air and water will be polluted significantly.
3. Large scale water consumption will result.
4. Montana will emulate the bad characteristics of other states.
5. Present life styles will be disrupted.

Many letters expressed disfavor with either Montana Power Company in general or with the population centers outside of Montana that would use some of the energy. Many letters and all of the coupons merely ask us to deny the permit for construction without any particular reason being stated.

There were two major misconceptions expressed or implied by the large number of correspondents. First, many people appear to believe that all of the power from the Colstrip plant will be used outside of Montana, and that Montana needs no additional generating capacity to meet its own needs. Second, most letters were written seemingly with the belief that the Air Quality Bureau could decide to issue or deny a permit on the basis of popular opinion or criteria other than the standards established in the regulations. The articles in the Gazette promoted this misconception.

There was a substantial amount of confusion expressed in the letters about the role of the Department of Health. The non-degradation clause from the Air Quality Implementation Plan was cited as evidence that the State should oppose construction of the plant. However, since in its literal interpretation, non-degradation is not possible, and since at the national level, the legality of non-degradation laws and variations thereof is before the U. S. Supreme Court, the Department does not feel it has the authority to enforce a literal interpretation of non-degradation.

Exhibit 4

There was also considerable concern as to why construction of the plant was allowed to begin before a permit to construct was issued. The reason is that the State had no authority to regulate construction except for those portions of the plant that would contribute to air pollution.

All letters commenting directly on the draft statement are included in the Appendix, either verbatim or condensed form. One of these comments worth noting states that all the great civilizations of the past became more technologically complex as they advanced. It was further noted that the great civilizations of the past also share the common characteristic of no longer being around.

Exhibit 4

ARCHAEOLOGICAL SURVEY

Exhibit 4

Exhibit 4

The following is from an archaeological survey performed in 1971 for the Western Energy Company by Dale E. Fredlund and his team from the University of Montana.

Site Descriptions

Ellison Petroglyph Site (24RB1019). Site 24RB1019 is a rock art site located in the southwest quarter of Sec. 29, T2N, R41E. Four panels of petroglyphs (Figs. 2-5) have been drawn on the northeast vertical face of a stump-like, 25-30 foot high, eroded sandstone remnant that juts up at the end of a pine-covered ridge. Site 24RB1020, a habitation and lookout site, surround the art panels. The two sites, although adjacent, were assigned separate numbers because there is no way of ascertaining any direct association between the inhabitants of 24RB1020 and the individuals responsible for the art work at 24RB1019.

The four panels cover completely a flat, vertical sandstone face approximately 8 feet in height by 15 feet in width, but vary among themselves as to their individual dimensions and height above the present ground surface. Panel 1 covers an area approximately 4 by 2 feet (8 square feet) and is 4 to 8 feet above the surface. Panel 2 is also 4 by 2 feet (8 square feet), but covers an area from 3 to 7 feet above the surface. Panel 3 is smaller, being only 2 by 2 feet (4 square feet), and is at a height of from 4 to 8 feet above the ground. Panel 4 is 2½ feet by 1 foot, and is the lowest of the panels, being at a height of only 0 (surface) to 1½ feet. In addition, one large sandstone boulder, which had fallen face-down from the sandstone wall within the past 10 years, was reported to have exhibited numerous figures. It was impossible to move the boulder in order to verify the lead, but it seems reasonable that the report is valid.

Many motifs are still clearly visible on the panels, despite damage due to weathering. Based on the superimposition of some of the figures and on the various

Exhibit 4

art elements present, it seems very likely that more than one group of people were responsible for this art work. Grooves, lines, and various human and animal figures have been etched and rubbed into the soft sandstone.

Art styles frequently found throughout the Northern Plains occur in Panels 1-3, as follows: 7 shield-bearing warriors; 3 V-necked anthropomorphs, 2 solid body, square-shouldered anthropomorphs; 3 outlines, square-shouldered anthropomorphs; 2 horses with feathered arrows in their backs; 1 tipi; and numerous lines and arrows.

Superimposition occurs on all three panels, but the following should be noted especially: the lines dissecting the V-necked, outlined shield bearer and the square-shouldered anthropomorph in Panel 1 are etched over the figures; the V-shouldered anthropomorph occurs over an incomplete circular design on Panel 2; and a V-shouldered figure is superimposed on a square-shouldered figure in Panel 3.

Art elements similar to those in Panels 1-3 occur at the following sites, as noted by Conner and Conner (1971-17):

Pictograph Cave, pictographs (Mulloy 1958)
Pryor Creek, No. 2, pictographs
Bear Gulch, pictographs (Secrist 1960)
Atherton Canyon, pictographs (Secrist 1960)
Decker Site, petroglyphs
Deer Medicine Rocks, petroglyphs
Nordstrom-Bowen, petroglyphs (Hagen 1963)
Langman Petroglyphs, petroglyphs

In addition, several other sites in the area of Colstrip display these art forms, especially 24RB1027, the Benjamine Hill site, located near the Western Energy survey area on Rosebud Creek.

While the elements on Panels 1, 2, and 3 are fairly common in the Northern Plains, Panel 4 is atypical. The style present is, to my knowledge, not reported from any other site in the state. The art work on Panel 4 (Fig. 5) consists of frequently connecting curved lines, and rotund heads with short "crew-cut" like hair and smiling faces. The low height of this panel above the present ground surface (1½ feet) and the advanced stage of its decomposition suggest that it was

Exhibit 4

the work of a different and earlier group of people than those who were responsible for Panels 1-3. A test pit was excavated below this panel; however, fallen sandstone blocks have sealed off any information which might be gained from the site (see 24RB1020 for the test report).

Ellison Rock Site (24RB1020). Site 24RB1020 is a habitation site which extends 100 yards upslope and away from the sandstone remnant exhibiting the petroglyphs of 24RB1019. The site also includes a high sandstone remnant which had been used prehistorically as a lookout site.

The ridge is covered by native grasses, prickly pear, sage, and sparse ponderosa pines. Various types of brush grow along the bottom of an adjacent dry wash which contains water for at least part of the year.

Three artifacts were found on the surface of the site: a small side-notched projectile point, and two granite-tempered, dark gray plain ware pottery sherds. A small test pit was dug at the base of the sandstone remnant under the rock art panels. The top level of the revealed strata was 2-6 inches deep and consisted of dry, wind-blown sand and surface duff. Below this stratum was a stratum of gray sand which extended to bedrock, at a depth of 19 inches below the surface. The sand stratum was composed of compacted sandy soil and sandstone fragments with scattered charcoal, and evidenced much rodent activity. From the test pit were recovered one projectile point, three scrappers and the remnants of a hearth.

The projectile point is a small side-notched type, 2.6 cm. long by 1.2 cm. wide by 0.3 cm. thick. One of the blade edges is straight, the other convex. Of the three scrapers, two are flake scrapers, both exhibiting fine pressure retouch on one edge only. One scraper is a plano convex end-scraper of tan chalcedony. This scraper is very well made and exhibits controlled primary percussion scars on the dorsal surface. Pressure retouch is evident along the lateral edges and nose of the scraper. Part of one hearth made of fragmented sandstone rock was found resting on the sandstone bedrock. It did not contain sufficient carbon for radiocarbon dating.

Exhibit 4

Farley Ridge Site (24RB1022). Site 24RB1022 is located slightly northwest of the Farley ranch building, along the base of a low sandstone outcrop ridge that extends into the basin. Small concentrations of debitage are found intermittently from the base of the sandstone ridge to its junction with the higher pine-covered ridges.

It is possible that because the ridge provided concealment, it was used as an approach route to game animals grazing on the flats.

Western Energy Shelter (24RB1033). Site 24RB1033 is located in the northeast quarter of Sec. 32, R41E, T2N. The shelter faces southward and is slightly above the floor of the east-west extending dry wash that dissects Sec. 32. Ponderosa pine, chokecherry, and native grasses constitute the vegetation of the immediate site surroundings.

Debris from lithic tool manufacture was found on a low sandstone outcrop directly above the rock shelter. Because of the proximity of the debitage, it was felt necessary to test the shelter for subsurface cultural material. The shelter was excavated to a depth of 49 inches below surface at which point bedrock was encountered. The subsurface strata consisted of sand deposited by wind and water, and rock sloughed from the shelter's ceiling.

At a depth of 5 inches below the surface was encountered a fragmented wood floor composed of 2-inch thick, sawed planking, some of which still evidenced green paint. Other historic items recovered included a metal can, glass, and cloth fabric found at 11 inches below the surface. A concentration of charcoal at about 12 inches below the surface suggests that part of the wood sturcture had burned.

Another south-facing rockshelter located during the survey had formed at the base of the sandstone outcrops in the southeast one-quarter of Sec. 8, R41E, T1N. The shelter measured 25 feet wide by 10 feet deep. Cow manure mixed with wind-blown sand covered the entire floor area. No surface indication of human habitation was detected. However, since the shelter would have

Exhibit 4

provided excellent protection and concealment for prehistoric peoples, testing of the floor deposits was warranted. A test location near the center of the cave's length on the outer lip of the floor was selected. Below the surface mixture of sand and cow dung was encountered clean, aeolian-deposited, compacted sand stratum disturbed by occasional rodent holes and with occasional rock that had sloughed from the ceiling. There was no indication of human habitation. Consequently test excavation was terminated 36 inches below surface level, at a point where sloping bedrock was encountered.

The Cattail Site (24RB1015). Site 24RB1015 is located on the second terrace above Armells Creek. Surface debitage extends for approximately 100 yards along the terrace. The vegetation in the immediate area includes cottonwood and chokecherry along the creek, and sage and native grasses on the terraces. Because the cultural deposits are entirely on the surface, cultivation has caused considerable damage to the site. Thus, I felt the site warranted no further study.

EMISSIONS EFFECTS

Exhibit 4

Exhibit 4

INTRODUCTION

In January, 1972, the Montana Agricultural Experiment Station initiated a preliminary investigation into the effects of coal-fired power plant stack emissions on the range resource in the vicinity of Colstrip, Montana. This study was the initial step of a potential program extending over several years. It was requested and supported by the Montana Power Company through the Endowment & Research Foundation of Montana State University. The objectives of the investigation were to:

1. Gather literature and information on coal-fired generating plant emissions and monitoring systems.
2. Inspect the site of the power plant and the adjacent areas.
3. Prepare a realistic and comprehensive proposal for implementation of a formal study.
4. Submit a budget for the investigation.

Substances Recommended for Study

Of the elements or gases already discussed, arsenic, poly-nuclear hydrocarbons, carbon monoxide, and gaseous hydrocarbons have not been considered in this category. Levels of these substances in the plant emissions will be extremely low or the pollutant may be readily removed from stack gases and hence to not warrant expensive analyses.

An analysis of fly ash for radionuclides should be made. If an estimation of particulate fallout and radionuclides shows a potential accumulation problem, a monitoring program should be initiated. Calculated maximum concentration that could possibly be derived from power plant emissions should always be significantly lower than maximum permissible concentrations in air as established by the Public Health Service.

Sulfur Dioxide:

This gas has been shown to produce toxic symptoms in several sensitive plant species at very dilute concentrations in the atmosphere. Ponderosa pine and alfalfa

Exhibit 4

are very sensitive to sulfur damage and are common in the study area. Atmospheric concentrations as low as 0.1 ppm sulfur dioxide produce injury in sensitive plant species if the fumigation is extended over prolonged periods of time (Hindawi, 1968). Because of the known presence of sulfur sensitive plants near Colstrip, the atmospheric concentration of sulfur will be very critical in this area.

The sulfur content of an individual plant is a poor indicator of plant damage or of environmental sulfur contamination since plant sulfur is quite variable. Vegetative sulfur concentration depends upon the species of plant analyzed and environmental conditions during the growth of the plant in addition to the rate and length of sulfur fumigation. In some instances, sulfur concentrations may be higher in healthy plants than in sulfur damaged ones and sulfur injury, if any occurs, can only be interpreted by visual inspection. Plant damage should be reflected, however, in the average sulfur content of a plant species.

Sulfur contents of vegetation established prior to power plant operation and compared to sulfur levels in the same plant species after operation of the generators will yield valid judgments as to the extent of sulfur fumigation during operation of the generating complex.

Oxides of Nitrogen:

These oxidizing substances are quite damaging to various plant species. Nitrogen dioxide is especially damaging to plants during periods of cloudy skies and high humidity. Some plant damage may occur in early summer at Colstrip if the oxides of nitrogen are released in sufficient quantity during this period of rapid plant growth. The function of nitrogen oxides in the formation of smogs was discussed under the emission of hydrocarbons in the previous section of this proposal.

Because of the wide variation in plant nitrogen concentrations no analytical technique has been developed that will allow interpretation of nitrogen contents of vegetation as an indicator of plant damage. Diagnostic study of affected vegetation

Exhibit 4

can reveal nitrogen oxide damage to vegetation only after it occurs.

At the present time sulfur dioxide and nitrogen dioxide damage are very difficult to describe analytically. To develop a picture of atmospheric concentrations of these two gases, a monitoring of existing air quality is strongly recommended. Data avilable from the sampling sites established by the Montana Power Company to monitor air quality and a diagnostic survey of vegetation should reveal the extent of sulfur and nitrogen oxide damages.

Fluoride:

Reports of the toxicity of this element to cattle are usually associated with aluminum reduction works or phosphate fertilizer plants because of the massive release of fluorides from these operations. Fluoride levels in the coal to be utilized at Colstrip and the rate of coal utilization anticipated at this plant justify close examination of the accumulation of this element in plants and animals on the range near the power plant.

The main route of fluoride accumulation in plants will be by foliar absorption since plant roots absorb little fluoride from the soil. In addition to absorbed fluoride some particulate matter high in fluoride will be found on plant leaves. It is inevitable, therefore, that animals feeding in the area influenced by stack gases from the Colstrip power plant will accumulate fluoride in their tissues. However, the low fluoride level in the coal, the retention of fluoride in fly ash, and the removal of hydrogen fluoride gas by wet scrubbers should reduce fluoride emissions below critical levels and fluoride should not pose an environmental hazard under the present production schedule at Colstrip.

Fluorides accumulate in skeletal tissues of mammals and produce damage by altering the normal molecular structure of these tissues. This action in cattle has been extensively studied and the probability of toxic accumulation because of the Colstrip power plant is remote. Much less is known of the effect of this element on wildlife and this facet of the total fluoride picture will be investigated

Exhibit 4

along with the accumulation in cattle.

Ponderosa pine, the most common tree in this area, is especially sensitive to fluoride damage. If atmospheric fluoride concentrations exceed the limits tolerated by this pine, an early loss of needles can be predicted. A decrease in the vigor of these trees may result in increased insect damage, and die off of most of the trees in the fumigated area will likely follow within a few years.

Mercury:

The toxicity of mercury has been well documented and federal levels in meat have been established. If mercury emissions are high enough, the movement of small amounts of mercury through the food chain may cause liver or kidney levels in range cattle to exceed federal tolerance limits without visible damage to the animals. The resulting economic loss to the ranchers in the study area could be substantial.

Selenium:

Several species of the genera Astragulus and Stanleya are known to accumulate selenium from the soil in which they are growing. Western wheatgrass (Agropyron smithii) has also been identified as a selenium accumulator but at lower levels than the other species. These plants are found in the Colstrip area and western wheatgrass is one of the dominant grasses on parts of the range in this area. Cattle generally avoid selenium accumulators but will not ignore the more common palatable grasses on the range. Thus, high selenium levels in western wheatgrass could be quite damaging on this rangeland.

A selenium concentration in cattle feed as low as 4 ppm is considered by some authorities to be the minimum level in food at which this element may accumulate in animal tissues and ultimately produce the characteristic signs of selenium toxicity (Underwood, 1962). Low levels of selenium, if present in stack emissions, could contribute sufficient quantities of this element to the soils of the area and permit range plants to approach this minimum critical selenium level.

Exhibit 4

Cadmium & Lead

These two elements are accumulative poisons similar to mercury. While neither of these is absorbed by terrestrial plants from the soil in appreciable quantities, foliar absorption and contamination does take place. If low level emissions of either of these elements from the power plant occur, food chain transfer and accumulation will take place and concentrations within the liver or kidneys of range animals will be elevated.

Unlike mercury, federal tolerance levels for cadmium and lead have not been established for foods destined for human consumption. The Environmental Protection Agency is presently considering such levels and long term accumulation in range cattle may pose economic problems for ranchers attempting to market animals from areas contaminated by cadmium or lead.

Beryllium and Chromium:

These elements are relatively unknown in the field of trace metal studies. Their extreme toxicity has been established and their carcinogenic properties substantiated by several investigators. Until the concentration of these two elements in the coal to be utilized at Colstrip has been determined and soil and plant levels analyzed, they should be viewed with caution. If emission of these elements occurs, the movement of the metals in the ecosystem will be carefully monitored.

Recommendations:

The present state of our knowledge of emissions from fossil fuel burning plants is fairly sophisticated. We can analyze the fuel or stack emissions for elemental composition and interpret meteorological data to determine fallout patterns. Unfortunately, our knowledge of the effect of many of these emissions on vegetation and animals or of synergistic effects of combinations of two or more of these emissions is very limited. In view of these facts it is recommended that selenium, cadmium, lead, beryllium, and chromium concentrations in soils, forage and cultivated

Exhibit 4

vegetation and animal tissues be established before the generating plant becomes operational in 1975. Monitoring of these elements after this date will reveal changes in the concentration of these metals in the appropriate compartment. If significant changes in the elemental composition of any trophic level occur, potential damage to the range resource will be implied. Trophic level concentration changes will preceed visible signs of range deterioration by one to several years and corrective action may be implemented before substantial damage to the range resource has taken place.

Plant damage due to sulfur or nitrogen dioxide in the atmosphere has been established but their influence on animals is still the subject of much research and debate. Since there are no present techniques to evaluate plant damage by these emissions other than by visual inspection of damaged vegetation, an air monitoring program for total sulfur and oxides of nitrogen is appropriate. Constant monitoring of atmospheric sulfur and nitrogen oxides will indicate if these atmospheric levels approach minimum toxic limits for the sensitive plants in the area. Furthermore, sulfur levels in dominant vegetation will be established prior to plant operation and monitored after power production has begun. Sulfur accumulation in the dominant species will be established by this procedure and the extent of sulfur dioxide fumigation after 1975 assessed.

Fluoride levels in vegetation and animals should be determined before 1975 and monitored after full plant operation. Cattle, deer, and antelope are found on the ranges near Colstrip throughout the year and will be subjected to increased fluoride uptake if substantial quantities are emitted by the powerplant. Elevated fluoride levels on vegetation of the area could be quite harmful to animals spending their entire life span on these ranges.

Mercury should be monitored in terrestrial animals and aquatic organixms. Although preliminary analyses of the coal to be burned indicate "normal" mercury levels

Exhibit 4

at least one published report has indicated elevated mercury levels in coal from Rosebud County. Until mercury concentrations in indicator organisms have been established before and after plant operation, this toxic substance must be viewed with caution.

Exhibit 4

Exhibit 4

WILDLIFE AND ECOLOGICAL REPORT

Exhibit 4

Exhibit 4

The following is from a preliminary wildlife and ecological report prepared by the Ecological Consulting Service of Helena for the Western Energy Company and Stearns-Roger Corporation.

The survey covers an area 10 by 20 miles, which the consultants believe is the area possibly affected by emissions from the proposed generating plant. Along with the wildlife study, the consulting service will analyze the downstream effects of removing the estimated 8,000 gallons per minute cooling water from the Yellowstone Riber. The effects on fish, irrigation, municipal and recreational uses will be studied.

I. DESCRIPTION OF STUDY AREAS

A. Location and History

The five areas of study are adjacent to Colstrip, Montana. They include A & B, Old Spoils, Experimental and Control areas. Colstrip has an approximate population of 266 persons most of whom have some connection with mining or construction activity in the immediate area. There has been periodic strip mining for coal in the vicinity for more than 50 years.

The study areas were investigated for wildlife species and vegetative communities which support them. Historically, the general Colstrip area has supported a large wildlife population and was used by Indians. With settlement, the area was used for raising livestock with the valley bottoms and other suitable areas cultivated for agricultural use. A comparison of the writings of early explorers and inhabitants of the area reveal an alteration of its vegetative complexes through a century of heavy grazing and other agricultural practices.

However, livestock and agricultural use has co-existed with an abundance of native wildlife and a few exotic species of introduced wildlife. Just prior to the 1900's, wildlife was at a low ebb throughout Montana but good conservation practices and improved range management allowed most wildlife species to build until, in the mid-fifties, deer population reached a peak statewide. By the late sixties, deer and

Exhibit 4

antelope populations and other wildlife species became stabilized with better harvest methods and hunting seasons more closely geared to available winter range.* Today, eastern Montana is one of the better wildlife areas of Montana. Areas A and B amount to approximately 6/10ths of one percent of Deer and Antelope Hunting District 72 in which they are located.

B. Physical Description and Vegetative Communities

1. Area A

2. Area B

These are the two areas proposed for strip mining of coal. They lie adjacent to each other immediately west of Colstrip with State Highway No. 315 as their common eastern boundary. Each area is approximately 3 miles east-west and 1½ to 2½ miles north-south. Each area contains approximately 5½ square miles with a collective total of about 11 square miles, and mining will be done only where the overburden is less than 150' deep.

Area A is bounded on the north and Area B is bounded on the south by higher elevation east-west ridges with Ponderosa Pine-type forests of varying density. The ridges slope to a rolling-type terrain on the valley bottoms, which consist of grassland types where the major portion is under agricultural cultivation. Lands cultivated for wheat and alfalfa in Areas A and B amount to slightly less than 1 square mile.**

An intermittent stream, the East Fork of Armell's Creek, drains the major part of both Areas A and B and serves as the arbitrary east-west dividing line between Area A and B. The East Fork joins the main stream of Armell's Creek at Colstrip. Armell's Creek flows past Colstrip in a northerly direction approximately 35 miles to the Yellowstone River.

---

*Montana Fish and Game Department Environmental Statement, "Annual Statewide Harvest of Big Game Animals", Project no. FG-22, July 24, 1972.

**Calculated from Montana Power Company map

Exhibit 4

Two major vegetative zones occur on both Area A and B: Ponderosa Pine and Sagebrush-Grassland. The Ponderosa Pine Zone occupies the northern part of Area A and the southern part of Area B. The elevations of the Ponderosa Pine Zone run from about 3,400 feet to about 3,600 plus feet. The Sagebrush-Grassland Zone occupies the remainder of both areas from an elevation of about 3,300 feet to 3,400 feet. In the total of Areas A and B there are approximately 5 square miles in the Ponderosa Zone and 6 square miles in the Sagebrush-Grassland Zone. The two zones are not clearly defined in all areas and a gradation from one to the other is common. The widest variety of plant species and associated wildlife occurs within the ecotone between Zones.

3. The Old Spoils Area

This area is east and south of Colstrip where spoil banks and piles date from 1921 to the present. The old spoils ridges are characterized by steep slopes and sharp tops. Some faces of the old spoils are nearly barren of vegetation and others are heavily vegetated by volunteer species in complex and radically differing communities and are used by a variety of larger wildlife. Wildlife species in the area were studied to comment on the value of the old spoils to wildlife.

4. Experimental Area

Reclamation experiments are being conducted in various places among the spoils area by Dick Hodder et al.* Experimental areas have been shaped to gentler slope and terrain configuration and carry a variety of planted and volunteer types of vegetation and receive some wildlife use. However, since the areas have only been established for 4 years, it is too early to determine the potential degree of wildlife use which can be expected as vegetation becomes more fully established. The area was studied for some comparison of wildlife use on the untouched spoils areas and "reclaimed" areas.

---

*Coal Mine Land Reclamation Research (Reports from 1968 through 1972.)

Exhibit 4

5. Control Area

A control area was established on the Don Bailey Ranch approximately 12 miles south of Colstrip. It was chosen as a place similar to Areas A and B and which was unlikely to be disturbed by major land use changes in the near future. Studies were made on comparable vegetative zones for comparison with Areas A and B and the Spoils Area.

C. Additional Data

1. Climate and Weather

The average annual precipiation in the Colstrip area is about 15 inches, with the number of frost-free days varying from 115 to 120 days. The weather is characterized by sudden and extreme changes with blizzards, hail, high winds, snow and drought being part of the "average". Summers can be extremely hot and winters very cold and severe. Temperatures may vary from 100° F. to minus 40° F. From spring 1972, to date, precipitation has been above average with a periodicity that has produced exceptional plant growth.

II. WILDLIFE

A. Game Birds*

1. Observed or identified:

a. Sharptailed Grouse . . Pedioecetes phasianellus . . . (all)

b. Ring-necked Pheasant . Phasianus colchicus. . . . . (7)

c. Sage Grouse. . . . . Centrocercus urophasianus . . (3)

2. Known to use the area, but not observed:

a. Mallard. . . . . Anas platyrhynchos . . . . . (8)

b. Greenwinged Teal . . . Anas carolinensis . . . . . (8)

c. Bluewinged Teal . . . Anas discors . . . . . (8)

d. Hungarian Partridge . Perdix perdix . . . . . (7)

---

*As defined by Montana law.

q. Grasshopper Sp . . . . . Ammodramus savannarum . . . . (7)

r. McCown's Longspur . . . . . Rhynchophanes mccownii . . . . (7,9)

3. Rare and endangered species*

Rare and endangered species are defined as those birds which, according to the Committee on Rare and Endangered Wildlife Species of the Bureau of Sport Fisheries and Wildlife, are so few in numbers or are so threatened as to be in danger of extinction.

No endangered bird species was in evidence in either the study area or in the general vicinity. The Prairie Falcon, which is known to be in the area, is classified as a rare bird, but not an endangered species. In the opinion of a qualified ornithologist familiar with the area, Peregrine Falcons will not be found there.**

4. Birds of prey

Birds of prey were found throughout the entire area and also outside the perimeter of Areas A and B, with the exception of the Cooper's Hawk, which was seen only in the Ponderosa Pine Zone. The other raptors were seen over the entire general A and A areas.

5. Mammals -- Game Species***

a. Observed or identified:

1. Mule Deer . . . . . Odocoileus hemionus . . . . . (all)

2. Pronghorn Antelope . . . . . Antilocapra americana . . . . . (all)

6. Mammals -- Non-game Species

a. Observed or identified:

1. Predators:

a. Badger . . . . . Taxidea taxus . . . . . (all)

b. Raccoon . . . . . Procyon lotor . . . . . (all)

---

*As defined by the Committee on Rare and Endangered Wildlife Species of the Burau of Sports Fisheries and Wildlife

2. Others:

a. Thirteen-lined Ground Squirrel . . . . Citellus tridecemlineatus . . (1,7,10,11)

b. Least Chipmunk . . . . . Eutamias minimus . . . . . (6,9)

c. Northern Pocket Gopher . Thomomys talpoides . . . . . (all)

d. Western Deer Mouse . . . Peromyscus maniculatus . . . . (all)

e. White-footed Mouse . . . Peromyscus leucopus . . . . . (6,9)

f. Porcupine . . . . . Erethizon dorsatum . . . . . (all)

g. Eastern Cottontail . . . Sylvilagus floidanus . . . . . (all)

h. White-tailed Jack Rabbit Lepus townsendii . . . . . (all)

i. Little Brown Bat . . . . . Myotis lucifugus . . . . . (4,6,7,9)

j. Striped Skunk . . . . . Mephitis mephitis . . . . . (all)

k. Mink* . . . . . Mustela vison . . . . . (4,7)

b. Known to be in the area, but not observed:

1. Predator:

a. Long-tailed Weasel . . . Mustela frenata . . . . . (6,9)

2. Others:

a. Richardson Ground Squirrel Citellus richardsonii . . . . . (1,7,10,11)

b. Ord Kangaroo Rat . . . . Dipodomys ordii . . . . . (2,6,9)

c. Northern Grasshopper Mouse-Onychomys leucogaster . . . . . (2,6,9)

d. Western Harvest Mouse . . Reithrodontomys megalotis . . . (7,Ag.)

e. Meadow Vole . . . . . Microtus pennsylvanicus . . . . (4,7,Ag.)

f. Meadow Jumping Mouse . . Zapus hudsonius . . . . . (4,7,Ag.)

7. Rare and endangered species

Rare and endangered species are defined as those animals which, according to the Committee on Rare and Endangered Wildlife Species of the Bureau of Sport Fisheries and

*Furbearer, according to Montana law.

Exhibit 4

Wildlife, are so few in numbers or are so threatened by circumstances as to be in danger of extinction.

No endangered animals were in evidence in either the study area or in the general vicinity. The Black-footed Ferret, an endangered species, which is closely associated with Prairie Dog towns, could not be expected to be in the vicinity as no Prairie Dog towns were found in the area. However, there are Prairie Dog towns within 50 airline miles of Areas A and B. Wherever there are Prairie Dog towns, the possibility exists that the Black-footed Ferret is also present. This small predator lives in close association with Prairie Dogs and preys upon them. During 1971 and 1972, the Montana Fish and Game Department asked through its bi-monthly magazine for reports of any sightings of Black-footed Ferrets in Montana. Although several reports were sent to the magazine, to our knowledge at this time, there has not been a confirmed Black-footed Ferret sighting in southeastern Montana.

III. VEGETATION

A. Summary

Areas A and B and the Control Area contain very similar plant communities and very similar wildlife species and population densities. The Control Area was selected because it probably will not be disturbed for several years and can serve as a check for those areas which are mined and reclaimed. Portions of the Old Spoils Areas were chosen for study: One was representative of the old untouched spoil banks and the other was on Hodder's reclamation experimentation areas. Due to the extreme vertical and horizontal diversity of plant composition and the wide variance of plant invasion, no transects were established on the old spoils, but species present were investigated and listed.

B. Classifications

The vegetation within the study area was classified into two zones: (1) Ponderosa Pine and (2) Sagebrush-Grassland. The species composition of the vegetative zones and

Exhibit 4

types for which measurements were taken are given in Tables I. through VII. Locations of these vegetative transects are shown on the enclosed map. Plant types which were not quantitatively measured include the Rhus Sagebrush-Grassland type in the Ponderosa Pine Zone and the Agricultural type in both the Ponderosa Pine Zone and the Sagebrush-Grassland Zone. The Ponderosa Pine Zone was divided into seven vegetative types. These are:

1. Ponderosa Pine Type.
2. Ponderosa Pine-Juniper Type.
3. Big Sagebrush-Grassland Type.
4. Silver Sagebrush-Grassland Type.
5. Rhus Sagebrush-Grassland Type.
6. Caprock Gumbo-Knob Type.
7. Agricultural Type.*

The Rhus Sagebrush-Grassland Type was further divided into four sub-types, which are:

1. Rhus-Grassland.
2. Rhus-Big Sagebrush-Grassland.
3. Rhus-Silver Sagebrush-Grassland.
4. Grassland Park.

The Sagebrush-Grassland Zone was divided into five vegetative types. These are:

1. Big Sagebrush-Grassland Type.**
2. Grassland Type.
3. Silver Sagebrush-Grassland Type.
4. Creek Bottom Type.
5. Agricultural Type.

---

*Not included in Tables.
**Permission to investigate this type denied by landowner.

Exhibit 4

Few of the vegetative types were clearly defined within the vegetative zone. There is considerable overlap among the various plant types. There are approximately 5 square miles in the Ponderosa Pine Zone and about 6 square miles in the Sagebrush-Grassland Zone within Areas A and B. The Agricultural Type represented about ½ square mile in each area.

IV. WILDLIFE HABITAT COMPARISONS

A. Game Animals

1. Areas A and B mirror each other as wildlife habitat. Five mule deer (2 does, 3 fawns) were observed using the Ponderosa Type on Area A. One doe had a slightly deformed ear and was sighted twice.

Seven mule deer (2 does, 2 fawns and 3 bucks) were observed using the Ponderosa Type on Area B. None of these deer had identifiable individual characteristics.

Checking the vegetational species present with the available literature concerning the overall area reveals an abundance of known deer foods as shown on Table I. The literature indicates that the Ponderosa Type is very important in the mule deer's overall requirements in country such Areas A and B.

Although Areas A and B are important to the deer using them, they represent only 6/10ths of 1 percent of Hunting District #72.

As deer winter range, the importance of any part of Areas A and B is unknown. Winter range is the limiting factor of deer populations. Establishment of observation routes and food habits studies during the fall-winter-spring period would define the importance of the area as winter habitat.

2. The Control Area is so similar to Areas A and B that one could expect similar deer usage and interviews with the landowner (Don Bailey) support this. Establishment of observation routes and food habits studies during the fall-winter-spring period would enable a relationship of deer population presence and usage between the Control Area and Areas A and B to be established.

Exhibit 4

3. Areas A and B and the Control Area are only fair antelope habitat in comparison with the overall area. Two aerial and one ground sighting revealed a lone buck and a group of 3 does, 3 fawns, and 1 buck using the western edge of Areas A and B. Vegetation composition of the areas shows an abundance of known antelope foods.

4. The Experimental reclamation plots in the spoils did not reveal any significant deer use.

Tracks, sign and some observable use of known deer food plants showed the Old Spoils to be used by deer at some times of the year although no animals were observed. Our experience suggests the Old Spoils Area is useful to deer for food, cover and possibly winter range because of its configuration and vegetational content.

The usefulness of the Old Spoils to deer in winter would be regulated by snow depths. As long as the gulleys between the banks do not drift in too severely, food plants would be easier for them to reach there. Observation and plant use data during fall-winter-spring would be necessary to establish this fact. Interviews with local residents indicate the spoils are used by deer during the hunting season. Some hunters consider them favored hunting places. It would seem the deer find the juxtaposition of food and cover advantageous when pursued by hunters.

5. Fish

The East Fork of Armell's Creek does not support a sport or commercial fishery because the creek is intermittent in character. A few small ponds are found in northern Area A, but they have no fish in them. The nearest fishery, in the old box-cut at Colstrip, contains a variety of stocked warm-water fish and some stocked rainbow trout, according to local fishermen and the Montana Fish and Game Department.

V. COMMENTS ON WILDLIFE

A. Present Population

Presently there is a healthy wildlife population of both game and non-game species in Areas A and B. This population does not seem to have any unique features

Exhibit 4

which make it exceptional in comparison with other areas of southeastern Montana with similar terrain and vegetation.

B. Displacement with Mining

If strip mining progresses at the rate of about 100 acres per year and reclamation follows within a three-year period, during any given year of the estimated 35-year period, 300 acres of Areas A and B (more or less) will not provide any important wildlife habitat. The larger, more mobile species will avoid the immediate mining area, but the rate of mining will be slow enough to prevent significant impact on their overall population. At 100 acres per year mining rate, about half the total acres within Areas A and B would be mined during the 35-year life of the mine.

C. Impact on Small Mammals

Small mammals will be the most susceptible to population disruptions, but normally they are the first classes of wildlife to return to a disturbed area as it re-vegetates. This class is the most numerous in the food chain and has the highest reproductive potential. They also have high annual and cyclic population fluctuations even when man's actions are not a factor.

D. Impact of Increased Local Population

The estimated existing population of Colstrip is 266 with a projected increase to 1,855.* The Montana Fish and Game Department estimates that one person in three buys some form of hunting or fishing license. Applying the 1:3 ratio to the present Colstrip population indicates that about 89 hunting/fishing licenses are sold to residents. When the population increases to 1,855, the number of licenses will grow to 618. This would have a major impact on the immediate Colstrip vicinity including Areas A and B.

If Areas A and B are reclaimed for heavy recreational use, the mere activity of people will make the larger wildlife forms more wary of the area, especially during the daylight hours and in the milder months. Also, if reclamation includes high use

---

*Ken R. White Co. data.

Exhibit 4

recreational development, hunting is seldom allowed in these areas. The impact of human population on the game species would also be felt outside Areas A and B.

An increase in people brings a corresponding increase of domestic pets and will create an abnormally high "predator" density in a small area. House cats and dogs in uncontrolled or semi-controlled conditions will have some affect on the wildlife in the immediate Colstrip vicinity.

E. Effect of Artificial Lake

A body of water of any size in the A and B Areas, where none presently exists, would draw waterfowl, especially during migration seasons. Depending upon the vegetative complexes established around the lake, some nesting of various waterfowl species could be expected if human intrusion is kept at a minimum during nesting season. Only an occasional pond now exists in northern portions of Area A and no significant natural bodies of water exist in the Colstrip vicinity. The popularity of the artificial mini-lake created by the seepage filling an old box-cut at Colstrip demonstrates that a more amenable body of water would receive high use from people living in the area.

F. Consideration of Small Mammals, Raptors and Predators

Preliminary findings on the Old Spoil Area and the Experimental Area show no signs of burrowing animals establishing themselves there. To some types of burrowing animals, such as pocket gophers, soil types are almost as important as vegetation types. If the habitat conditions of the reclaimed land on Areas A and B do not provide the needs for burrowing animals, the food chains utilized by predators and raptors will be affected. The absence of these burrowing animals on reclaimed areas will reduce the food supply for them and one would not see as many of them utilizing this reclaimed area. However, raptors have great mobility and the size of the area is small enough that they will fly past or over the area.

In a predominantly high-use recreational area, small birds and small mammals are susceptible to destruction due to the thoughtlessness and carelessness of people.

Exhibit 4

AGENCY AND PUBLIC COMMENTS

Exhibit 4

Exhibit 4

Because of space requirements, it was necessary to condense some letters commenting on the Draft Statement, as follows:

Name	Main Points Raised
Richard A. Wortman Consulting Geologist Bozeman, Montana	Stated efficiency of scrubbers doubtful. Other plants at Fruitland, New Mexico, Casper, Wyoming, and Kemmerer, Wyoming, have much lower scrubber efficiency than promised by operators.
Montana Chapter American Assoc. of University Women (unsigned)	Too many unknown facts about long term effects. Statement should contain definite information on pipeline size. No permit should be granted until the possibility of using dry towers is assessed. More documentation needed on particulate removal. Impact on schools not assessed. Energy conservation might eliminate need for plant, saving money to use in developing more efficient generating techniques.
Ron Schleyer Billings, Montana	Insufficient cause seen for violating "non-degradation" clause in Air Quality Implementation Plan. Biocides in cooling towers might cause impact on biota. Dry towers could be used.
Margaret Busha Sweet Grass County Treasurer Big Timber, Montana	Stop the plant; save Montana for Montanans.
American Association of University Women Edith Gronhoud Jean M. Evans Billings, Montana	A moratorium should be placed on this and similar developments until legislation is passed to adequately safeguard the environment and guarantee complete land reclamation and until other alternatives to construction of the plant are thoroughly studied.
Vincent Amicucci, M.D. Vice President, Audubon Society Helena, Montana	Industry must take care to safeguard the environment. Construction of additional plants could threaten minimal flows in the Yellowstone River. Site approval by the State should be required.
Mrs. William F. McKinney Birney, Montana	Draft statement contained insufficient data on fluorides and mercury. Dust from strip mining will cause health hazard. Large scale water evaporation could cause weather alterations. EPA or the state should monitor plant emissions, rather than the plant owner. What effect will ash have on groundwater? Future generations will be sorry if plants are built.
Mavis McKelvey Montana League of Conservation Voters Missoula, Montana	Non-degradation clause in the National Environmental Policy Act should be upheld. Burning coal at 30% efficiency not economical. Increased tax base caused by industrial development more than eaten up by needed services. Employment will not continue indefinitely. Ghost towns in Montana demonstrate futility of expecting long term

Exhibit 4

	returns from mining. Additive factor of emissions may occur between emissions from Colstrip and Billings. Much power wasted. New York City uses 65% of its power in lighting, including empty office buildings. Montana should call a halt to further despoilation.
American Association of University Women Elizabeth Miller, Chairman Bozeman, Montana	Statement does not provide clear evidence that the known facts outweight the known facts enough to justify issuance of permit. No more than one plant should be permitted until the first one has been evaluated to answer pertinent questions. Plant was under construction two years before respondent was asked to comment. Additive effects between Billings, Colstrip plants will occur. Computer modeling inadequate since it was not based on established fact. Trace element analysis needed. Scrubber efficiency on mercury vapor needs to be known. More information needed on emission of fluoride and radioactive materials. Weather modifications possible from humidity increase from cooling towers. Small changes in the ecosystem resulting from emissions should be carefully monitored, and when damage appears pollution should be abated. The alternatives portion should have listed alternatives and generating developments expected in the next 5, 10, or 20 years. Energy consumption should be moderated through changes in the price structure used by utilities. Coal consumption should be slowed and continued at a low rate over a long period, with boom bust cycle scaled down to a permanent economic asset for the area. Technological advances in coal conversion techniques and solar energy should be encouraged.
Carolyn and Irving Alderson Ranchers Birney, Montana	Federal non-degradation clause should be enforced Total effects of strip mining, water diversion from Yellowstone River, construction of transmission lines, all contribute to environmental degradation. The number of unknown factors cited in the statement are evidence that a permit should not be issued. The vast coal generating complex in the Southwest should have been analyzed for environmental impacts of the sort likely to result from the Colstrip project. Montana Power "arrogant" for beginning construction without a permit. Reclamation of strip mined land not proven for areas such as Colstrip. Strip mining might adversely affect groundwater. Considering the above, granting a permit would be irresponsible.
Montana Federation of Women's Clubs Mrs. William Graham Wyola, Montana	Sulfur dioxide and other emissions would have a serious detrimental effect on wildlife, livestock, and surface water.
Doris Milner Montana Wildlife Federation Hamilton, Montana	Water diversions, structures, aqueducts, pumping stations, transmission lines, and other facilities appurtenant to the generating stations have impacts that were only skimmed over in the draft statement. Cumulative impact

Exhibit 4

	of the plant and related facilities should be assessed in the final statement. An independent assessment should be made of the need for the electricity to be generated. The extent of state control over generation facilities not clear in the draft statement. Public should be alerted to the minimal control available to the state over power plant construction.
Michael Williams, Ph.D. Los Alamos, New Mexico	The 90% collection efficiency of fluorides estimated in the draft supplement is too high. Other plants release as much as 97% of fluorides into the air. Predicted fluoride concentrations seem inaccurate. No statement about what conditions they are based on is included in the supplement. Higher values seem to be indicated. TVA experience indicates the maximum 24-hour average is about one-fourth the maximum one-hour average as opposed to one-seventh as stated in the supplement.
Mr. and Mrs. Art Hayes Birney, Montana	Pollution concentrations should be monitored at all times. If standards are violated, the plant should be shut down. Otherwise, the surrounding lands will be rendered unproductive. Instead of building mine-mouth plants, the coal should be shipped to the load centers, with a stiff tax. If the plant is built, dry cooling towers should be required.
Christine S. Jones Birney, Montana	Montana Power Company negligent in not investing in research on other types of generating equipment. Geothermal power is being developed seriously in Japan, Mexico and Russia. Fly ash buried in spoil banks will cause major pollution problems in the future. Temporary construction workers will have drastic social effect on the area. High fluorides in emissions are a serious health hazard to the nearby Northern Cheyenne Indians, who already have a high TB rate, along with other pulmonary and respiratory ailments. Gradual increase of radioactivity over the life of the plant will lead subtle ill effects in the ecosystem. Monitoring of emissions from the plant should be done by the state. Coal should be mined underground.
Robert R. & Joan Tully Ranchers Roundup, Montana	Mercury pollution could result from power plants. Air pollution effects from large generating plants are not known. Large size of the proposed plants indicates fluorides and sulfur dioxide could reach dangerous levels even if within standards. How many dangerous air pollution events will be allowed under the law? How much water can be taken from the Yellowstone River without causing ill effects downstream? Reclamation is impossible in arid regions such as Colstrip. Why was construction allowed before a permit was issued? If there is no check on power plant construction, how can it be assured that future plants will not be under construction before emission effects from the proposed plant are assessed adequately?

Exhibit 4

Exhibit 4

Because of space requirements, it was necessary to condense some comments that were submitted for the record during and after the public hearing in Miles City, January 5, 1973, as follows.

Name	Main Points Raised
Berkeley and Cynthia Dowd Fishtail, Montana	Draft Statement written in a cursory manner, violating the intent of the Montana Environmental Policy Act. Most information in the draft was supplied by the Montana Power Company and not critically reviewed by the state. No permit should be issued until the Montana Power Company has proved no environmental degradation would result from the plant construction and operation.
Frank Dunkle Ecological Consulting Service Helena, Montana	The Montana Power and Western Energy Policy of "determining accurately what the present ecosystem of the Colstrip area really is today, is fundamental to answering accurately what effects mining and power generation may have on Colstrip and Montana. Sound information is the only realistic basis for comparing short and long range values of natural resources."
Byron J. Bennett, Ph.D. Dean of Engineering Montana State University Bozeman, Montana	Energy shortage is developing. No alternative to planning well for the continued use of coal reserves for at least 20 years. Well financed and organized research needed on alternate types of generation. Gas turbine research should be speeded. Research efforts on alternate generating techniques have "been surface efforts compared to what is needed." The finest air pollution equipment is planned for the Colstrip plant. It would be terrible if we were forced to exist with none of the gas or electric services now provided by Montana Power. Electricity indirectly required for auxiliary fans and pumps in most heating systems. Electricity needed to solve environmental problems.
The League of Women Voters of Montana Grace Edwards Billings, Montana	Analysis of coal needed, especially to determine mercury and fluoride content. Acid rain and fog likely to occur from mixing of plumes of stacks and cooling towers. More information needed on meteorology of the area, and of possible weather modification resulting from the plant, before construction is allowed. The discussion in the draft statement concerning the influx of population is inadequate. What plans exist to handle the influx? What will happen to the area population after the plants no longer function? Montana Power Company should live up to its claim of being a good citizen by working openly and cooperatively with state government and smaller political subdivisions.
Steven Jessen, Editor Forsyth Independent Forsyth, Montana	Economic impact of the plant is already felt in a more stable economy, a widened tax base, and increased prosperity in the area and elsewhere in Montana. The taxed collected by Rosebud County will double by 1976. The best interest of the people of Rosebud County and Montana are being served by developing the coal.

Exhibit 4

Jerry Landa Broadus, Montana	The population of the sparsely people areas are in no way obligated to sacrifice their health, their property, and their way of life for the big population centers elsewhere, as would be accomplished by the operation of power plants. Coal deposits should be kept for future emergencies. The permit to construct should be denied.
Bill Zumpf, President Miles City Chamber of Commerce Miles City, Montana	The Chamber welcomes new business, new industry and the development of all resources. Total membership of the Chamber not agreed about coal development. The Chamber endorses construction of the plants, within the limits of existing law.
Nick Golder, Rancher Colstrip, Montana	Agriculture is the backbone of Montana's economy, and will remain so if allowed to by the coal developments. Power shortage may be manipulated by big money and big government. Fluoridated water can be dangerous. Fluoride emissions need further study.
Albert Bud White	Coal development provides God-given opportunity for people to work. Jobs are needed. The state can best serve the majority of the people by providing environmental ground rules that will permit the development of natural resources in an orderly manner, without interruptions and the resulting loss of jobs. Should not build a fence around Montana.
Montana Chamber of Commerce	Adequate electrical power is an integral factor in the continued economic growth of any region. The Colstrip plant will meet or exceed existing regulations for ecological protection. The Board should grant the permit. Population in Rosebud County decreasing in numbers, increasing in average age, indicating unattractive total human environment.
R. D. Shipley Beacon Carter Service Miles City, Montana	What we do on our own private deeded land is our own business entirely. Environmentalists should be limited to regulating land they own. Coal is needed to combat the energy shortage. Reclamation is possible if strictly regulated. Grazing will be almost restored and the difference in the kinds of plant life will result in improved game habitat and, therefore, in hunting of a different but highly acceptable kind.
Robert J. Shy Custer County Rancher	Individuals and corporations have the right to do what they want with privately owned land. The Colstrip plant should be permitted, provided reasonable control is used and the surface lands are replaced or reshaped to the best possible use. Coal should be mined the same as any other resource.
Chuck Searl Executive Vice President, Billings Chamber of Commerce Billings, Montana	Plants at Colstrip should be completed, if they can meet existing and future air pollution standards. Power plant operation should not be allowed if it detracts from the life giving forces of the Yellowstone. The Chamber currently favors only the two 350 MW plants now under construction. Montana will need the electricity by the time the plants are completed.

Exhibit 4

Harry Swain Swain and Morris Construction Company	Existing businesses need more electricity. Farms need more electricity. Oil fields need more electricity. Living standards should not be lowered by trying to conserve electricity by not using air conditioners, radios, televisions, and other appliances that some call luxury items.
Chris Angle	More local industry, power, and employment needed to give stability to the state economy. 87% of students graduated from state colleges leave the state to get work.
Thomas B. Breen, President Empire Steel Manufacturing	The energy crisis is real, and Empire Steel, along with the rest of modern society, needs a reliable source of electrical energy. The Colstrip plant should be built.
John L. Hansen, President Cop Construction Company Billings, Montana	Construction of the Colstrip plant is necessary; the pollution control equipment will keep emissions within standards; and delays in construction will be detrimental to Montana. The next decade will bring the need for 500 more megawatts than now available. Montana Power Company peak loads exceeded their capacity in December, 1972, requiring import of power. If outside power was not available for purchase, industrial power would have been interrupted, causing economic loss. A power shortage impends, and coal-fired thermal plants are the only apparent remedy.
Roy E. Huffman, Ph.D. Vice-President for Research Montana State University Bozeman, Montana	The University does not conduct secret research. Data collected in research at Colstrip is available to state agencies and others with a need to know. When fully interpreted, research results will be available in published reports. MSU is working on meteorological studies for Montana Power Company. Montana Power Company personnel have displayed a sincere interest in determining the air pollution potential at Colstrip, so as to be able to meet state and federal air pollution standards. MSU has worked on reclamation at Colstrip for Western Energy since 1968. Other studies in progress for Montana Power Company include work on the effects of stack emissions, trace element analysis of coal. The sponsors of the research have made no attempt to influence the results of the studies, and they have been fully cooperative.
Robert A. Ratliff, Manager Billings Refinery, CONOCO Billings, Montana	Coal production should be doubled in the next 15 years to meet the energy crisis. Crude oil imports will have to quadruple. Montana must be concerned about the energy crisis. Billings refinery has experienced 17% compounded annual increase in electrical energy use. More energy yet will be needed, and a reliable source is a must.
James R. Beaty	Should be no urgency in marketing coal, as the energy crisis will cause a continued market. No need to increase Montana pollution to supply energy for out of state. No reclamation effort can be evaluated for at least ten years after all reclamation efforts have ended and the land subjected

Exhibit 4

to the forces of nature. If coal were hauled by rail to plants near the load centers, Montana would benefit from a stronger rail system. High voltage power lines will not move grain, lumber or other goods into or out of Montana. Strip mining should be permitted on a limited scale for ten years, to be followed by evaluation of the effects on land and water. Shipment of coal should be encouraged over mine mouth plants. No major generating plants except hydroelectric should be allowed unless 50% of the output will be used in Montana or adjacent states contributing directly and strongly to the Montana economy.

I. D. Peterson
Midland National Bank
Billings, Montana

Energy crisis is real; generating facilities must be developed to avoid dependence on outside energy sources. Economic and industrial development would stop without required energy. Tax base needed to supply the monetary needs of government. Colstrip plants should be built.

Louise Cross, Delegate
Montana Constitutional Convention
Glendive, Montana

Coal development occurring so fast that Montanans do not realize the environmental effects taking place. Much water will be used, the remainder polluted; productive land will be destroyed, and the air will be contaminated. Land is the only capital in Montana, and sustains Montanans when all else fails. Montana Power Company is building the plant without a permit, and will use the costs as an excuse to allow the operation of the plant. No public official will have the guts to shut down the plant no matter what it does to land, water, and air. Circumvention of the building permit sets a dangerous precedent for other companies. Power companies want to strip the land, ruin the water, take the coal, transport the power, and make the profits.

Exhibit 4

ITEM
#5

STATEMENT

on the

"Draft Environmental Impact Statement on the Proposed Montana Power Company Electrical Generating Plant at Colstrip, Montana"

by

The Montana Power Company

Presented at

Miles City, Montana

January 5, 1973

Exhibit 4

Exhibit 4

STATEMENT OF

THE MONTANA POWER COMPANY

The Montana Power Company and Puget Sound Power & Light Company on the 14th day of August 1972, filed a joint application, pursuant to the provisions of the Clean Air Act of Montana and the Regulations issued under that Act, to the Air Quality Bureau of the Department of Health and Environmental Sciences for a permit to construct and install equipment and machinery which are capable of emitting air contaminants into the atmosphere and for the construction and installation of equipment for eliminating, reducing and controlling the emission of such air contaminants.

The construction and installation of such equipment and machinery is in connection with two 350 megawatt steam electric generating plants to be constructed by the joint applicants at Colstrip, Montana.

Pursuant to the Montana Environmental Policy Act the Department of Health and Environmental Sciences has issued a draft environmental impact statement directed to the application to construct and install such equipment and machinery. This hearing is directed to the consideration of that draft impact statement.

This statement is made in the belief that The Montana Power Company can and should make constructive comments at this hearing. This statement refers only to the first draft of the Air Quality Bureau's Draft Environmental Impact Statement and if we have additional comments on the supplement to that draft, we

Exhibit 4

will submit them in writing before the record is closed.

Our comments are intended to supplement the material in the Draft Impact Statement. We ask that they include our remarks in the final environmental impact statement. We feel this would be appropriate since we are the applicant for the Construction Permit.

NEED FOR POWER

The projected electric requirements for consumers in The Montana Power Company's service area show that if the Colstrip Project is not built the Company will fall short of meeting the needs of its consumers by about 20% by 1975. This means that not only will no new customers be connected but that some existing customers will be curtailed or cutoff.

Montana Power Company generation, together with purchased power, served the 1971-1972 winter peak load with 124,000 KW to spare. 144,000 KW of power purchased in 1971-1972 will not be available to Montana Power Company by the winter of 1975-1976 because the electric suppliers now selling us this power will need it for their own customers. An additional 27,000 KW of purchased power will be lost to Montana Power Company by the winter of 1976-1977.

The Montana Power Company load historically grows at approximately 5% per year. We see nothing which will substantially change this. If the Colstrip units are not constructed, Montana Power Company will be 174,000 KW deficient by the winter of 1975-1976. Montana Power Company will be deficient by 246,000 KW by the winter of 1976-1977.

Exhibit 4

DESIGN PROCEDURES PRIOR TO CONSTRUCTION PERMIT APPLICATION

There has been some confusion expressed in various public statements regarding the procedure used to design and build a project of this complexity; specifically, questions have been raised as to why we do not have all details of the project designed at the time of application for a construction permit.

In order to design an installation such as this, it is necessary to know all details about every item of equipment to be used, including such things as dimensions, weights, location of connections to other devices, electrical power and control requirements, steam and water flows, nature of materials of construction, etc. No manufacturer, whether he be a supplier of a small water pump or a large steam generator, can afford to provide reliable information of this type until he has actually received an order for his equipment. In order to buy an item of equipment, engineers must first specify the overall operating conditions and the general nature of the devices. With this kind of specification, bids are then invited on a competitive basis and analyzed. Afterward an order can be placed with a supplier and only then can the information necessary to design some other effected feature of the plant be obtained. In this situation, in order to design a power plant, the procedure is to specify and invite bids on the largest and most costly items that have the longest delivery and construction times. This procedure must begin at a point in time sufficiently ahead of the date at which the plant will be required. Steam generators and turbine-generators have lead times of four to five years. After this equipment has been ordered, the manufacturer can provide information that can be used to write specifications, invite bids and place orders for a

Exhibit 4

level of equipment that has somewhat less lengthy delivery and construction periods. After this level of equipment has been ordered, information from its suppliers is again used to specify the next level of equipment and so on. In the meantime, enough time may have elapsed that it is necessary to start building foundations for the first level of equipment and perhaps portions of the equipment itself, even though all components and features of the final plan have not yet been determined.

While this overlapping of construction and engineering activities may cause a small amount of uncertainty in some parts of the plans for some period of time, the procedure has one outstanding advantage. By not specifying and buying items of equipment until the point in time is reached when it is necessary, then any new developments in equipment designs can be incorporated in the bid specifications. In this way the latest available technology can always be incorporated into each system of the plant. If this had not been the case and we had had to specify our air quality equipment at the same time as the steam generator was specified, the newly emerging technology of wet scrubbers could not have been incorporated into the plant design because it had not been adequately demonstrated in early 1970 when the steam generator was ordered. Initial planning for this increment of generation began in 1968, making a total elapsed time from planning to finish of seven years.

Under these circumstances, it should be clear that many details of the design will not be known at the time that a construction permit must be applied for.

If a procedure were followed whereby all engineering, and there-

Exhibit 4

fore all equipment purchasing, was completed prior to the time that an application for a permit is submitted, then major investments would have to be made in engineering time and equipment orders that might not prove to be the most logical. Such a waste of resources is inconsistent with our responsibility to provide power to our customers at the lowest possible rate. Instead, in the case at hand, we followed the normal established procedure after discussing the schedule with State officials, and applied for our construction permit as soon as we had sufficient information about the air quality control equipment.

Exhibit 4

ADEQUACY OF EQUIPMENT TO MEET EMISSION STANDARDS

The air quality control equipment we have proposed represents the latest technology in methods of collecting sulfur dioxide from flue gases. In fact, the emission limitation published in the Federal Standards of Performance for New Stationary Sources was predicated on the availability and use of wet scrubbing equipment. The federal government was required by law to publish standards that were consistent with adequately demonstrated technology. When the federal standard of 1.2 lbs of SO_2 per million Btu heat input was proposed on August 17, 1971, the EPA published a report entitled "Background Information for Proposed New Source Performance Standards". We are attaching Pages 8 and 9 of that report which state that flue gas cleaning for sulfur dioxide removal is an adequately demonstrated technology. When challenged in this regard, the EPA has stoutly defended the position that this technology is adequately demonstrated with more public statements, reports and correspondence than we can reasonably list. These federal emission standards are somewhat stricter than comparable State standards.

The ability of this kind of equipment to also meet the particulate removal requirements has been demonstrated on numerous nonutility applications, and more recently at the Dave Johnston power plant at Glen Rock, Wyoming.

Furthermore, our equipment specifications have very strong guarantee requirements that would expose the supplier to substantial financial loss if the proposed requirements are not met. Yet when we invited bids on this equipment, an adequate number of bidders accepted these guarantee requirements expressing the same confidence in their

Exhibit 4

ability to provide equipment to meet the standards as has been expressed by the EPA.

The performance level of this equipment will be maintained continuously because we will install all of the continuous monitoring devices listed in the EPA regulations. With the monitoring equipment in service, the Company can not have excursions of the standards that will go undetected.

Finally, should any element of the control equipment begin to show a mechanical malfunction, there will be no recourse to us other than reducing the load on the plant and repairing the equipment, because there will be no bypass installed by which flue gas can be passed around the control equipment. Maintenance can be performed with the plant in service because the scrubbing system will be modularized into three separate units that can be independently operated. With this arrangement, it will be possible to reduce the plant load and isolate and repair any troublesome portion of the system while continuing in service with the remaining modules performing at their normal level of efficiency.

Considering the foregoing, we are convinced that the equipment can perform initially and in continuous service with the specified efficiencies.

Exhibit 4

SUFFICIENCY OF THE STANDARDS

Since the publication of the Draft Impact Statement there have been a number of public protestations that meeting the applicable standards should not be considered sufficient in spite of the statement on the adequacy of the standards on Page 12 of the Draft Statement. We would, therefore, like to adress ourselves to this subject.

First, we point out that for the most part performance will be substantially better than applicable emission or ambient standards.

The federal emission standards, which are slightly stricter than comparable State standards, are based by law on whatever degree of emission reduction can be adequately demonstrated.

Furthermore, both the federal and State agencies that published ambient standards designed them so that they are more than just barely good enough. To quote from the Montana Ambient Air Quality Standards, Regulation No. 90-015, "The air quality standards listed describe a level of air quality designed to protect people from the adverse effects of air pollution; and they are intended further to promote maximum comfort and enjoyment in use of property consistent with economic and social well-being of the community". Further, the federal government in publishing national primary and secondary ambient air quality standards pointed out that their primary air quality standards define levels of air quality which protect the public health with an adequate margin of safety. They defined their more stringent secondary ambient air quality standards as levels of air quality which protect the public welfare from any known or anticipated adverse effects of a pollutant.

The Colstrip Project will meet whatever standards are the strictest

Exhibit 4

Since these standards are the judgment of the responsible federal and Stage agencies, they should be the basis of judging the performance of the plant.

Exhibit 4

DISPERSION CALCULATIONS

After equipment was specified to limit emission rates to levels at or below allowable standards, calculations were made to predict the contribution of the proposed plant to ambient air quality levels. The Draft Impact Statement says the State also made such calculations and gives their results. The principal reason for making these calculations is to select a stack height. On the basis of our dispersion calculations, a 500-foot height was selected.

Most of the results reported by the State are well under any applicable standards, and our own calculations are in agreement on this point. However, there are enough differences between the State's results and our own that we are attaching the report of our consultant, W. L. Faith, for your reference. Dr. Faith, a longtime air pollution control officer of the County of Los Angeles, is well qualified in the field of dispersion modeling. His experience and association with similar experts employed by TVA, the AEC and others, help him to employ good mathematical techniques and sound judgment, and we rely greatly on his calculations. Even though both sets of answers appear favorable when compared to the ambient standards, we hope that as soon as we are able to submit the final meteorological report being prepared by researchers at Montana State University, we can review the two sets of dispersion calculations to identify any differences in procedure and preclude any future misunderstandings.

There is a prediction in the Draft Impact Statement with which we strongly disagree. This is the set of values predicted for SO_2 concentrations under fumigation conditions for periods of ten minutes, one hour and three hours. We have already submitted our predictions

Exhibit 4

for these conditions which are well under the applicable ambient standard, and we ask that our transmittal dated November 30, 1972, be considered a part of this statement. We understand that we are now in agreement with the State on the method of making calculations for these conditions. We recognize that some other set of meteorological conditions could be postulated that would give a different set of values than our own, but we are confident that any set of conditions that has actually been observed during the meteorological program would lead to a result that compares favorably with the applicable standard.

Exhibit 4

TRACE ELEMENTS

While we would not disagree with the sentence in the Draft Statement that only a limited amount of knowledge about the trace element content of Colstrip coal is available, this situation is not abnormal. Coals throughout the country have not been examined extensively for trace element content for good reason, there has been no consensus on the part of the scientific community that trace element emissions from coal burning operations are likely to be harmful. The trace elements in coal are common in many other naturally occurring substances and are an essential ingredient in small quantities for many growing things. They change in nature from a necessity to a problem only when concentrations are unusually large. Consideration of emissions of these materials should not be made without also considering the final concentrations.

Mercury

The Draft Impact Statement states that values of mercury in the coal range from less than .006 ppm to 0.7 ppm for the Rosebud seam. Other analyses indicate an average nearer to 0.3 ppm, but this includes concentrations as high as 6.25 ppm which have been found in the pyrite in the coal. Coal pulverizers reject pyrites. During tests conducted by our Company, 19 samples of coal were taken at the discharge of our pulverizers using Colstrip coal and were analyzed by Truesdail Laboratories. The average content was 0.076 ppm when corrected to the as-received moisture content. Corresponding samples of ash discharged from the boiler at the same time were isokinetically taken and analyzed for mercury. These tests showed 97% of the mercury in the coal appears in the ash and can be removed by ash collection equipment. This would mean that less than .002 lbs/hr of mercury will

Exhibit 4

be emitted from the two units combined. Resulting ground level concentrations would be in the order of .0000003 $\mu g/m^3$.

The EPA has stated concentrations of 0.1 $\mu g/m^3$ is well below the level at which health or welfare effects have been observed. We are attaching the applicable reports, calculations and correspondence to support our conclusions.

Fluoride

The 19 samples referred to in the previous discussion were also analyzed for fluoride content. We have previously submitted the information that the average content was 4.2 ppm referred to the moisture content of the samples taken. We have been advised that subsequent tests on four samples have given higher values and that the values reported by different laboratories are not in agreement. We have no reason to disbelieve the results of the 19 samples we had analyzed. The importance of the information obtained from our tests is that the corresponding isokinetically taken ash samples showed at least 70% of the fluoride appearing in the coal also appeared in the ash and can be removed by ash collecting equipment. Any gaseous fluoride will be highly soluble and can be easily removed by the wet scrubber. These conclusions are consistent with references in the literature such as Pages 540 and 541 of Stern's "Air Pollution", Vol. III, where the use of alkali scrubbing systems is described for uranium ore and phosphate plants where uncontrolled fluoride emissions would be a problem. The importance of this is that when estimating emissions, full consideration should be given to the effects of collection equipment.

Due to the discrepancies in the previously reported fluoride tests,

Exhibit 4

we cooperated with your organization in taking additional samples under carefully controlled and standardized procedures. The samples were taken over the seven-day period from last December 16 to December 22. They were blended and split for analysis by the state and by our Company. Our portions are being analyzed by three different commercial laboratories, including Truesdail Laboratories. The results available to date are generally consistent between the various laboratories and average for the series about 22 ppm when corrected to the moisture content of the coal as received at the plant. We have attached all of the results available to this date and will submit a complete tabulation as soon as possible. We believe when you compare this tabulation with your own tests the results will be consistent.

Even if all the coal to be burned in the proposed plant had a fluoride content equal to the highest reported value, the fluoride emissions after considering the effect of the collection equipment would only be 8.3 lbs/hr based on particulate collection alone. At the average fluoride content, the emission would be 5.1 lbs/hr, and the resulting ground level concentration would only be .01 ppb compared to the ambient standard of 1.0 ppb or 1/100th of the State standard. Calculations showing this have been attached. If gaseous fluorides are also collected as can be expected, these numbers would be even lower.

Radioactivity

We have not tested for radioactive material in our coal and have no reason at this time to disagree with the values given by the State in the Draft Impact Statement.

We do, however, ask that recognition be given to the available

Exhibit 4

literature, such as Stern's "Air Pollution", Vol. I, Section 5, where it is reported that radioactive particles in coal burning operations associate themselves with the particulate matter, and therefore they can be removed by the collection equipment. By taking the values reported on Page 124, Line 3, for typical emissions and correcting those values for the radioactive content reported by the State and the degree of dust collection to be installed on the Colstrip Units, it can be concluded that radioactive emissions will be in the order of .047 grams per year of radium or equivalent. Our calculations showing this have been attached. For the Colstrip Project, the corresponding annual average ground level radioactivity would be in the order of 9 X 10^{-8} REM/yr. The AEC recognized limit of safe exposure is 0.5 REM/yr, or about five million times as much. The predicted amount for Colstrip could not be expected to cause a change in the naturally occurring radiation level of about .18 REM/yr. The exposure from the plants would be 500,000 times less than would be encountered in living in a wood-frame house in Montana.

Exhibit 4

DRY VS WET COOLING TOWERS

All processes which convert heat energy to mechanical energy must reject heat to their surroundings in accordance with the laws of thermodynamics. The use of flow-through cooling is not possible with current water quality regulations so power plants must use some sort of cooling device to discharge waste heat to the atmosphere. The most commonly used device for this purpose is the evaporative cooling tower which has been used on thousands of industrial installations including several in Montana.

Dry type cooling towers, rather than evaporative type, have been considered for use on the Colstrip Project. Dry type towers are being developed in this and in foreign countries for use where water is not available in even the relatively small quantities needed by evaporative towers. The controlling factor in dry tower design is the dry bulb temperature, which is usually considerably higher than the wet bulb temperature that evaporative towers depend on. This means that where dry towers are used, the plant must have a lower efficiency thereby causing more fuel to be used for the same amount of electric generation and more heat to be discharged to the atmosphere.

In addition, dry type towers can not transfer heat as efficiently as evaporative towers so that for the same job a dry tower is much larger than an evaporative tower.

In terms of the Colstrip Project, these differences could cause:

1. About 15% poorer plant efficiency.
2. About a 13% reduction in plant capacity.
3. About five times as much land required for cooling towers.
4. About six times as much cost for cooling towers.

Exhibit 4

In addition, the most significant factor is that there is no accumulated experience anywhere, either in this country or abroad, in the use of dry cooling towers on power plants approaching the size of the Colstrip plants. Extrapolating the limited experience available on small plants to the Colstrip Project would be highly speculative. Based on the above, dry towers should not be considered an available alternative at this time.

Exhibit 4

VISIBILITY EFFECTS

On Page 21, the Draft Impact Statement quotes paragraphs from the Department of Health, Education and Welfare publications discussing particulate and sulfur dioxide concentrations that coincide with certain visibility ranges. We would like to point out that for the lower visibilities to occur, the concentrations reported would have to be pervasive throughout an entire air basin such as the urban areas referred to. The conditions in these areas are caused by emissions from multiple sources. However, in the case of the Colstrip installation, which is a single point source, the estimated ground level concentrations are applicable only for single points in the area and would not at all be representative of the general air character. Therefore, the evidence cited to justify the conclusion that visibility might be reduced is not applicable to the Colstrip situation.

Exhibit 4

SUMMARY

To summarize this statement, the following points have been made:

1. The project must be constructed to avoid a shortage of electric power.
2. The design procedure for a complex project is such that many details of the design can not be known at the time that a Construction Permit must be applied for.
3. The proposed air quality control equipment is capable of performing at the specified levels initially and in continuous operation.
4. The information published by public agencies describes the air quality standards as being compatible with the promotion of economic and social well-being and adequate to protect people from known or anticipated adverse effects of pollutants. The Colstrip Project will meet such standards.
5. There are technical but not significant differences between our predictions of ambient air quality contributions and those of the State. The only one in which compliance with an ambient standard is affected is the set of values for SO_2 concentrations under fumigation conditions. Using the agreed upon techniques and current data, calculations show that the standard would be complied with.
6. Mercury, fluoride or radioactive emissions wil not cause any problems particularly after consideration is given to the effect of the air quality control equipment.

Exhibit 4

7. Dry cooling towers are not a logical or feasible alternative for this project.
8. Visibility will not be noticeably affected throughout the area.

Exhibit 4

The fact that most low-sulfur fuel oil or crude oil will have to be imported from Alaska or from foreign countries. Substantial quantities of desulfurized fuel oil will be available from Caribbean facilities, several of which will go on-stream in 1971 and 1972.

The fact that naturally occurring low-sulfur coal is restricted for the most part to the Rocky Mountain area, so that shipping costs to eastern and midwestern power stations can be appreciable. Coal-cleaning techniques can be used to remove substantial portions of sulfur and ash from some coals, but the processes are highly dependent on the make-up of the coal.

The fact that stack-gas desulfurization processes have only recently been developed to the point at which they can be applied to steam generators. The first new steam generators to be affected by the standards will be put into operation in 1975 and 1976. In many cases owners and operators can delay decisions on air pollution control equipment for a year or longer after the steam generator has been designed. At that time there should be a greater number of options for sulfur dioxide control schemes from which to choose.

JUSTIFICATION OF PROPOSED STANDARDS

The proposed performance standards are based on inspections and tests of prototype and full-scale control systems, on consultations with state and local officials and operators and designers of steam generators and control systems, on EPA surveys of available combustion fuels, and on review of the literature. Essentially all of the technology applicable to the subject was developed in the United States.

Exhibit 4

The adequately demonstrated techniques include the use of electrostatic precipitators for particulate removal, low-sulfur fuels and flue-gas cleaning for sulfur dioxide removal, and combustion modifications for nitrogen oxides abatement. For the most part, these systems have been developed independently for each pollutant. The best systems for sulfur dioxide and particulate removal have not necessarily been operated on the same coal-fired steam generators. Many of the nitrogen oxides control techniques have been developed on units fired with low-sulfur fuel oil and natural gas, which had no requirements for sulfur dioxide or particulate control.

Particulate Matter

The particulate limits are based primarily on EPA tests of existing electrostatic precipitators that were reported to have high collection efficiencies. Seven precipitator-equipped steam generators were tested during coal burning using the EPA test method. Two of the installations were shown to meet the particulate limit, and two more barely exceeded the limit at 0.21 pound per million Btu. At the most effective precipitators only a trace of the emissions was visible.

Tests of the one scrubber showed particulate emissions of 0.32 pound per million Btu. The marble-bed scrubber, however, was designed principally for SO_2 removal rather than high-efficiency particulate control. Information obtained from various pilot-scale test programs indicates that advanced scrubber designs can achieve the particulate standard of performance. Full-scale scrubbers are now being installed at large steam generators. They have been designed to meet particulate levels that are consistent with the standard.

December 6, 1972

Mr. D.T. Berube
Montana Power Co.
Electric Building
Butte, Montana 59701

Dear Dan:

I am attaching a report showing the maximum ground-level concentrations of various pollutants that may be expected from the 2-360 mw units being constructed at Colstrip. An appendix to the report shows the methodology used in making the calculations. The maximum concentrations shown are well within all applicable Montana and Federal standards.

The actual emissions from the plant represent, in my opinion, best available technology.

Sincerely yours,

W.L. Faith

December 29,1972

Mr. D.T. Berube
Montana Power Co.
Electric Building
Butte, Montana 59701

Dear Dan:

For the record, in my report "Air Pollution Effects of Colstrip Unit 1" dated December 5,1972, the particulate emissions shown in the Appendix (0.1 lb per million Btu/hr heat input) are those allowable under EPA regulations.

I understand that the emissions of particulate matter actually expected are 0.038 lb per million Btu/hr heat input. In that case, the maximum annual mean ground level concentration of particulate matter will be 0.039 ug/m^3.

Sincerely yours,

W.L. Faith

Exhibit 4

APPENDIX

Pertinent plant design and operating data are:

2 - 360MW boilers each with a 500-ft stack
Heat input per hour per boiler - 3410×10^6 Btu/hr
Stack gas temperature - 175°
Stack gas velocity - 90 fps
Stack gas sp.ht - 0.259 Btu/lb/°F
Stack gas flow - 4609×10^3 lb/hr/stack

Emissions data are:

SO_2 - 1.0 lb per million Btu/hr heat input
NO_x - 0.7 lb (calc. as NO_2) per million Btu/hr heat input
Particulates - 0.1 lb per million Btu/hr heat input

Plume rise calculations:

Taken from "Plume Rise" by G.A. Briggs, U.S. Atomic Energy Commission, 1969

Unstable and neutral - Briggs'Eq. 5.1
Stable - Briggs'Eq. 5.7

where $s = 2.22 \times 10^{-4}$ for Category E
$s = 4.71 \times 10^{-4}$ for Category F
$s = 5.99 \times 10^{-4}$ for Cateogry G

Dispersion calculations:

No inversion:
short-term glc - Turner's "Workbook" Eq. 3.3
long-term glc - Turner's "Workbook" Eq. 5.13

With inversion(trapping):
short-term glc - Turner's "Workbook Eq. 3.5

Inversion breakup (fumigation):
TVA inversion breakup model - see Eq. 3 "Principal Plume Rise Dispersion Models: TVA Power Plants", J. Air Poll. Control Assoc. Aug. 1971, pp. 491-495

Correction factors

To change from concentrations derived from use of 10-minute σy and σz values, multiply by 0.74 for one hour and 0.62 for 3-hours.

Exhibit 4

AIR POLLUTION EFFECTS OF COLSTRIP UNIT 1

W.L. Faith
Consulting chemical engineer, San Marino, CA

Colstrip Unit No. 1 consists of 2-360MW coal-fired boilers each served by a 500-ft. stack. Other design and operating data, including emission data, are shown in the Appendix.

Calculated maximum ground-level concentrations (glc) of emitted pollutants are listed below (in comparison with applicable standards, if any)

	Maximum glc	Applicable standard
SO_2 - 1-hour	0.089 ppm	0.25 ppm
- 3-hour	193 ug/m^3	1300 ug/m^3
-24-hour	9.6 ug/m^3	260 ug/m^3
- annual mean	1.08 ug/m^3	60 ug/m^3
Particulates - 24-hour	1.0 ug/m^3	150 ug/m^3
- annual mean	0.1 ug/m^3	60 ug/m^3
Nitrogen oxides - annual mean	0.76 ug/m^3	100 ug/m^3
Mercury 24-hour	3×10^{-6} ug/m^3	None (proposed -0.1 ug/m^3)
Fluoride - 24 hour	<.002 ppb	1 ppb

(See Appendix for methodology of calculations)

Exhibit 4

(from Turner's"Workbook" p.38).

To correct for lower maximum glc brought about by use of 2 stacks and calcualting plume rise from one stack only, multiply glc by 0.9. (See "Recommended Guide for the Prediction of the Dispersion of Airborne Effluents, ASME, 1968).

Data for 24-hour calculation:

Meteorological tower data indicate most persistent wind was 22 hours of Stability D and 2 hours of Stability C in a SE direction. Used Turner equation 5.13 and no corrections.

Data for annual mean calculation:

Meteorological tower data indicate greatest annual concentration will be in sector resulting from a NW wind, which occurs 11.1% of the time. Makeup of wind is essentially 3% Class C at 5.5 m/sec; 8% Class C at 8m/sec; 3% Class C at 10 m/sec; 9% D -5.5; 39% D-8; ;2% D-10; 3% E-5.5; 13% E-8; and 5% E-10. Class G was ignored as it would contribute little. The small amount of Class F was distributed between E and G classes.

Long-term X/Q values for each of the above were averaged on a weighted basis for various distances from stacks.

Highest average X/Q (1.13×10^{-8}) occurred at 10 miles. This value was multiplied by amount of total emissions in micrograms per second and by percentage of NW wind (11.1%) to yeild maximum annual concentration in micrograms per cubic meter.

Other sources of emission data

Mercury emissions - 0.002 lb/hr, based on experimental data showing that 97% of mercury in coal remains in ash.

Flouride emissions - 0.8 lb/hr, assuming 70% retention in ash.

Exhibit 4

ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

COPY
OWS

June 25, 1971

Honorable Clinton P. Anderson
United States Senate
Washington, D. C. 20510

Dear Senator Anderson:

I regret that Mr. McGowan's earlier reply to your letter of June 3, 1971 regarding mercury emissions from the Four Corners power plant at Fruitland, New Mexico, was not fully responsive to your inquiry.

There is a paucity of actual measurements of mercury concentrations in the stack effluents and ambient air in the vicinity of this power plant. Samples of coal taken in May 1971 from the mine supplying all the coal for the Four Corners plant were analyzed by Environmental Protection Agency laboratories and by three outside laboratories. The analyses ranged from 0.3 ppm to 0.6 ppm by weight of mercury. In addition, the State of New Mexico has taken composite coal samples over a three month period. These samples have been sent to Lawrence Radiation Laboratory for analyses to include mercury content. Results will be available early in July.

The State of New Mexico has contracted with Environmental Sciences Associates, Cambridge, Massachusetts, to sample, among other things, the water input and effluent, the stack gases, and the ash for mercury. Results are not yet available but are also expected early next month.

New Mexico will also shortly begin a stack sampling program for mercury emissions from these units. The Environmental Protection Agency has provided sampling equipment for this study. We expect that the results of these analyses will be available in about a month.

Geomet Incorporated of Pomona, California, was retained by the Southwest Research Information Center, Albuquerque, New Mexico, to sample the power plant's stack gases. At the end of May, 1971, Geomet sampled the stack gas after it had passed through the precipitators and reported 80-120 nanograms (billionth of a gram) of mercury per cubic meter of stack gases. These values appear to be low and suggest that some of the mercury is collected with the particulate matter that is removed by the electrostatic precipitator or reacts with the materials in the fire box and boiler flues.

Assuming for purposes of discussion that coal fired at this plant contains an average of 0.5 ppm by weight mercury, that the plant is operating at full capacity, and that none of the mercury is caught by the precipitator or elsewhere in the system, the calculated mercury emissions would be 27 pounds per day. These estimates are as follows:

Unit No.	Operating Capacity Megawatts	Coal Burned tons/day	Mercury Emissions lbs/day
1	175	2,180	2.2
2	175	2,180	2.2
3	225	2,790	2.8
4	795	9,870	9.9
5	795	9,870	9.9
Total	2165	26,890	27.0

Exhibit 4 (Over)

LAB NO.	MERCURY, ppm	FLUORIDE, ppm	Sulfur, %	Combustible Matter, % (Loss on ignition)
COAL ASH:				
22479	0.276	57.5	5.83	0.48
22480	0.163	26.	0.87	0.48
22481	2.201	5.	0.85	0.25
	0.88	29.5		

METHODS OF ANALYSIS:

Mercury
Each sample was digested under reflux with nitric, sulfuric, and perchloric acid with sodium molybdate as catalyst. When digestion was complete, an aliquot of the solution was analyzed for mercury by flameless atomic absorption, using a special 10 centimeter cell. A National Bureau of Standards sample was analyzed by this with an accuracy of ± 0.01 ppm (Theory 0.13 ppm, found 0.125 ppm)

Fluoride
Accurately weighed samples (approx. 5 grams) were treated with saturated lime water in nickel crucibles. After drying at 105°C the crucibles were ignited at 550°C. The ash was transferred to special fluorine stills, sulfuric acid solution added, and steam distillation was conducted until 100 ml of distillate was collected. The distillate was then analyzed by the SPADNS method (colorimetric). The detection limit was 1 ppm.

Sulfate in Ash
Weighed samples were extracted with hydrochloric acid containing bromine. After filtration the sulfate was precipitated as barium sulfate and weighed.

Combustible Matter in Ash
The ash was dried at 105°C. Weighed samples were ashed in platinum dishes. The loss in weight was reported as % combustibles.

Respectfully submitted,

TRUESDAIL LABORATORIES, INC.

Charlie A. Crutchfield

Charlie A. Crutchfield, Ph.D.
Technical Director

Exhibit 4

TRACE ELEMENT CALCULATIONS

I. Emission rate of fluorine and mercury

A. Fluoride

Average content of 19 sample run = 4.2 ppm

Average moisture of partly dried samples = 8.75%

Ash content equivalent to 4.2 ppm = 10.2%

Fluoride content of ash = 29.5 ppm

Coal equivalent =

$$29.5 \times 10^{-6}\# \text{ Fl}/\# \text{ ash} \times .102\# \text{ ash}/\#\text{coal}$$

$$= 2.95 \times 10^{-6}\# \text{ Fl}/\# \text{ coal}$$

% Fl in coal found in ash

$$= \frac{2.95 \times 10^{-6}}{4.2 \times 10^{-6}} \times 10^2 = 70\%$$

Fluoride emission rate =

$2 \times 385{,}500 \times 22.0 \times 10^{-6} \times (1 - .7) = 5.1\#/\text{hr}$ at the fluoride content of the 37 sample average

B. Mercury

Average content of 19 sample run = .091 ppm

Mercury content corrected to 23.9% H_2O

$$= .091 \times \frac{.761}{.913} = .076 \text{ ppm}$$

Mercury content of ash = 0.88 ppm

Coal equivalent =

$$0.88 \times 10^{-6}\# \text{ Hg}/\# \text{ ash} \times .102\# \text{ ash}/\# \text{ coal}$$

$$= 0.088 \times 10^{-6}\# \text{ Hg}/\# \text{ coal}$$

% Hg in coal found in ash

$$= \frac{0.088 \times 10^{-6}}{0.091 \times 10^{-6}} \times 10^2 = 97\%$$

Exhibit 4

Atmospheric diffusion calculations, based upon operational data from the power plant and meteorological conditions typical of the Farmington area, indicate that, under the most adverse meteorological conditions, mercury concentrations would not exceed 0.05 micrograms per cubic meter.

These concentrations may be compared to the threshold limit value of 50 micrograms per cubic meter that has been set by the American Conference of Government and Industrial Hygienists for industrial exposure over an 8-hour day, 40-hour week. Air quality standards for mercury have not been established, but based upon present medical evidence, 0.1 micrograms per cubic meter is well below levels at which health or welfare effects have been observed.

However, any emssions of a toxic substance are of concern to us, especially considering mechanisms by which they might enter the food chain. At the present time, our investigation of such mechanisms is only in the preliminary stages and no conclusions can be provided regarding the present issue.

With respect to the mercury content of fish from Navajo Lake, we can only speculate that some of the mercury emitted from this plant would find its way into the lake, but it is difficult to envision atmospheric emissions as the principal source.

Data in the Report on Mercury in the Environment, Geological Survey Professional Paper 713, 1970, indicate that the mercury content of sedimentary rocks in the Colorado plateau region which surrounds and includes the Four Corners area is extremely high. Such sedimentary rocks compose, or immediately underlie, more than 90 percent of the surface of the region. It may be that water entering the lake contains leached mercury.

As you may know, we have announced our intention to set National Emission Standards for three hazardous air pollutants: asbestos, beryllium, and mercury. The Clean Air Amendments of 1970 mandate that these standards be proposed by September 27, 1971. We are now in the process of assessing the sources and quantities of mercury emissions to the air, as well as available control techniques. Information to date indicates that on a national basis the combustion of fuel accounts for a substantial quantity of mercury emissions. However, as these sources are so widespread through the nation, no one source or area sources are believed to seriously affect the public health or welfare directly.

I hope this additional information is helpful. And I regret that it was not made available in our initial reply.

Sincerely yours,

/s/ William D. Ruckelshaus
Administrator

Exhibit 4

Radioactivity Calculations

From State Impact Statement:
Samples of coal tested contain

Radium	pCi/g
Uranium	0.7 and 0.77 ppm
Thorium	3 and 1.74 ppm

Stern reports on 1000 MW plant without dust collection using coal containing:
1.1 ppm ^{238} U
2.0 ppm ^{232} Th

Plant emitts: 350×10^{-3} curies ^{228} Ra from ^{238} U 0.79 ppm
550×10^{-3} curies ^{226} Ra from ^{232} Th 1.44 ppm

So 2 x 360 MW would give: 252×10^{-3} curies ^{228} Ra corresponding to 0.79 ppm ^{228} U
396×10^{-3} curies ^{226} Th corresponding to 1.44 ppm ^{232} Th

Now averaging State Impact Statement figures:
?U 0.7 and 0.77 — 0.735 ppm
?Th 3.0 and 1.74 — 2.37 ppm
?Ra 2.8 pCi/g — 2.8×10^{-12} curies/gm coal
or 2.8×10^{-12} gm

So using our coal and Stern's Emission figures (99.5% particle collection)
$\frac{0.735 \text{ ppm}}{0.79 \text{ ppm}}$ (1.26×10^{-3} curies/yr ^{228} Ra) = 1.17×10^{-3} curies ^{228} Ra

$\frac{2.37 \text{ ppm}}{1.44 \text{ ppm}}$ (1.98×10^{-3} curies/yr ^{226} Ra) = 3.26×10^{-3} curies ^{226} Ra

Now Radium from our coal
385,500 lb coal/hr-unit 9.23×10^{6} 24 hr
3.37×10^{9} 365 day yr

Mass Radium emission/yr
2.8×10^{-12} curies/GM $\times \frac{454 \text{ gm}}{\text{lb coal}} \times 3.37 \times 10^{9} \frac{\text{lb coal}}{\text{year}} = 4.28$ curies year

Collection 99.5% efficient
0.0214 curies/yr escape
x 2 units
.0428

Three sources and emission rates

^{228} Ra	1.17×10^{-3}	Curies/year
^{226} Ra	3.26×10^{-3}	
? Ra	$\frac{42.8}{47.23} \times 10^{-3}$	

or 0.04723 curies/yr or 0.04723 gm Radium/yr

Exhibit 4

Mercury emission rate =

$$2 \times 385{,}500 \times 0.076 \times 10^{-6} \times (1 - .97) = .00175\#/hr$$

II. Ground level concentrations

A. Fluoride -- The published State standard is 1.0 ppb, 24 hr average.

MPCo. prediction of SO_2 glc = 0.004, 24 hr average.

$$\text{GLC (ppm HF)} = \text{ppm } SO_2 \times \frac{\text{moles/hr fluoride (as HF)}}{\text{moles/hr } SO_2}$$

$$= 0.004 \times \frac{\frac{5.1}{19}}{\frac{6820}{64}} = 11 \times 10^{-6} \text{ ppm}$$

$$= 0.011 \text{ ppb}$$

B. Mercury - No standard published.

EPA states 0.1 $\mu g/m^3$ a safe value.

$$\text{GLC } (\mu g/m^3 \text{ Hg}) = \mu g/m^3 \ SO_2 \times \frac{\#/hr \text{ Hg}}{\#/hr \ SO_2}$$

$$= 11.0 \times \frac{.00175}{6820}$$

$$= 0.28 \times 10^{-5} = 0.0000028 \mu g/m^3$$

INTRODUCTION

This pamphlet presents a resume of the Plan for Colstrip, Montana, a company town owned and operated by Western Energy Company. Colstrip is located in southeastern Montana 30 miles south of Interstate 94 in Rosebud County. The town planning area is located between Highway 315 on the west and the Burlington Northern Railway lines on the east. Western Energy's property limits determine north and south boundaries of the planning area.

Expansion of mining operations and development of a steam electric generating plant by the Montana Power Company will stimulate growth and the need for additional housing, streets and other urban facilities. The Plan proposes a reasonable, ambitious development program which will benefit Western Energy from the standpoint of economics, public relations and employee relations. In addition, the following benefits can be expected:

(1) Minimal employee turnover can be achieved by compensating for Colstrip's geographical isolation with an attractive and functional community. Good educational and recreational opportunities, comfortable and attractive living quarters and ready access to commercial facilities will go far in fostering satisfaction among employees and their families.

(2) Higher employee morale and job performance should result from pleasant living conditions.

(3) Public relations of Western Energy can be enhanced by developing Colstrip as a model community and avoiding the historic image of the "company town". This concern together with reclamation of mined land are in the best interests of Western Energy Company.

SUMMARY OF THE PLAN

The fast growth rate projected for Colstrip by 1980 required that the Plan for Colstrip be flexible. The construction of homes, streets and other facilities must keep pace with the population influx and must adjust to any unforeseen alterations in the growth rate. Therefore, the concept of the Plan provides for future growth to develop in separate "pockets" surrounded by open space. This concept allows for physical growth to occur in one of several areas at a time, depending on the demand for housing. Three types of housing (single-family, apartments and mobile homes) also provide flexibility to meet the different housing needs of the population.

The following summary reviews population projections for Colstrip and major elements of the Plan: housing, commercial, community facilities, traffic and utilities.

POPULATION

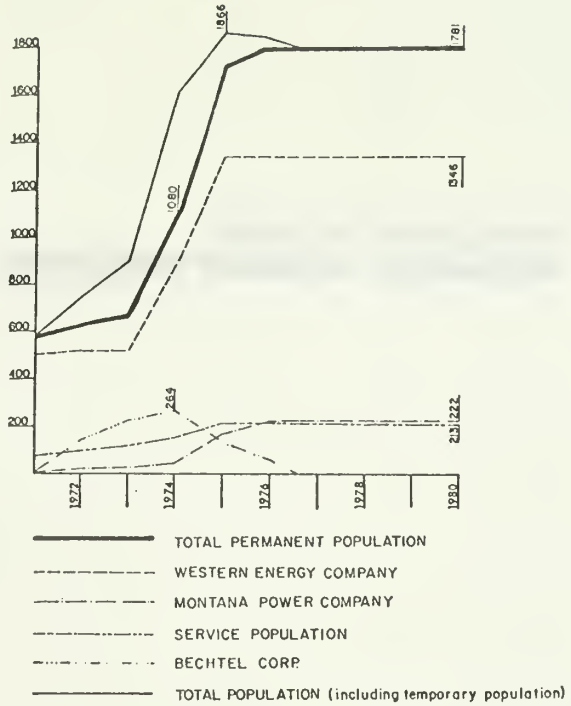
Colstrip's population is projected to grow to 1,780 by 1980, several times the current population. The following table and graph illustrate the yearly incremental increases in population.

POPULATION GROWTH
BY GROUP

Year	WECo.	MPCo.	Services Total	Bechtel	TOTAL
1972	522	17	91	140	770
1973	522	25	118	228	893
1974	885	42	153	264	1608
1975	1346	177	213	130	1866
1976	1346	222	213	63	1844
1978	1346	222	213	0	1781
1980	13[illegible]	222	213		

Exhibit 4

Population Growth



Projections were based on the following factors:

(1) Current census of Colstrip's population;

(2) Estimate of temporary construction employees and their families expected to live in Colstrip during construction of the steam electric generating project;

(3) Projected personnel and their families of Western Energy and Montana Power;

(4) Estimate of professional and commercial personnel required to serve professional, commercial and service businesses in Colstrip; and

(4) Factors establishing the single/married employee ratio and average family size.

Recommendations for relating the population growth to development of the town are as follows:

(1) Establish a system for monitoring population growth to keep abreast of changes in housing and other needs.

(2) Inform the school district of anticipated population changes and other demographic information pertinent to school planning needs.

HOUSING

Colstrip's rapid population growth requires a flexible housing plan. Construction must keep pace with the growth rate and be flexible to changing housing requirements and mix of housing types. To achieve flexibility, each new residential section is separate and surrounded by open space. Therefore, construction can vary from development of one section at a time to simultaneous construction of all sections. If the single/married ratio varies during a growth period from the projections, adjustments in the construction of apartments and single-family homes can also be accommodated. The following table relates projected population and households to anticipated housing requirements.

INCREMENTAL INCREASE OF
HOUSEHOLDS AND DWELLING UNITS
Colstrip, Montana

Year	Households	Dwelling Units by Type M. Fam.	Sing. Fam.	Mo. Home	Total
1972	230	38	64	128	230
1973	274	46	91	128	265
1974	412	61	199	128	388
1975	562	83	273	128	484
1976	551	95	273	128	496
1978	529	95	273	128	496
1980	529	95	273	128	496

Single-family homes are planned for three areas: (1) north of and adjacent to the existing single-family area in the northeastern part of the existing town, (2) in the southern part of the planning area between Highway 315 and the proposed mobile home park, and (3) north of the school to the limit of the planning area. Apartments are planned for the areas southwest and adjacent to the existing town and between the new mobile home park and the new single-family section to the south. The new mobile home park is planned south of the existing mobile home park and adjacent to the rail line.

Single-family homes should be located on lots with sufficient building setbacks to provide sufficient space between homes and to avoid a crowded appearance. Variation of setbacks for groups of houses can avoid a monotonous building setback appearance, particularly on long, straight streets. Variety in the styles of homes between each residential section can do much to provide variety in the visual appearance of neighborhoods. Predominant types of landscaping in each residential section will also enhance the visual appearance of neighborhoods.

Town house and garden apartments are recommended for new multi-family areas. Dwelling unit densities should range from 6 to 14 units per net acre for town houses and 15 to 20 units per net acre for apartments. Major design factors in developing multi-family areas are: (1) low land coverage and abundant open space, (2) privacy and quiet for the individual family, (3) adequate and convenient off-street parking for tenant's cars, and (4) convenient community shopping and recreation facilities.

Exhibit 4

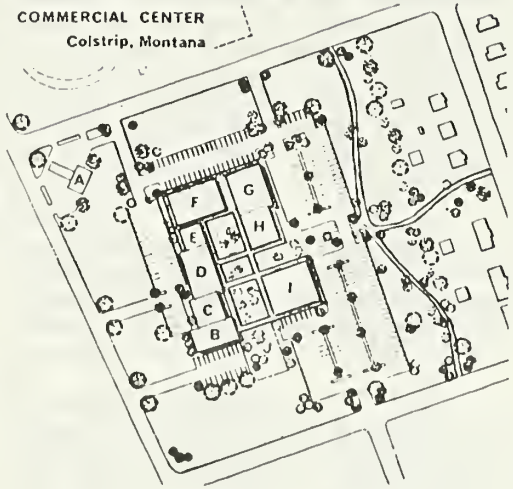
COMMERCIAL

Commercial development is planned for the area south of Main Street across from the school. The site is centrally located to serve both the community and highway traffic.

The proposed complex resembles a small neighborhood shopping center and consists of a grocery store, drug and hardware store, general merchandise store, offices, medical facilities, a post office and space for services such as a laundromat and beauty and barber shops. A service station, small motel and restaurant are located on the site and are oriented toward the highway. A recommended development plan for the commercial center is illustrated below.

Careful consideration should be given to design and aesthetics of the center as it is a major element in the future image of Colstrip. A market study should also precede development of the center to derive spatial requirements and quantity and range of merchandise.

COMMERCIAL CENTER
Colstrip, Montana



A. Service Station (14,000 sq.ft.)
B. 20 Room Motel (3,825 sq.ft.)
C. Restaurant (2,025 sq.ft.)
D. General Office Space (3,375 sq.ft.)
E. Medical-Dental Office (1,089 sq.ft.)
F. Drug-Hardware Store (3,666 sq.ft.)
G. General Merchandise (3,575 sq.ft.)
H. Commercial Services (2,475 sq.ft.)
I. Grocery (4,875 sq.ft.)
J. Future Expansion (optional)

COMMUNITY FACILITIES

Colstrip's community facilities include the school, fire and police protection services, churches, health care, library and parks and recreation services. Fire protection and parks and recreation are the primary responsibility of Western Energy; the other facilities are public or quasi-public facilities.

SCHOOLS — Although provision of additional school facilities is a public function, Western Energy should inform school officials of Colstrip's anticipated impact on school enrollment so appropriate action can be taken for school expansion. The present site can accommodate additional buildings, but additional playground and recreation space may be required. Agreements between Western Energy and the school district can bring about the mutual use of school recreation facilities and the proposed park north of the school site.

FIRE AND POLICE PROTECTION SERVICES — Fire protection will be a responsibility of Western Energy. A fire station is recommended to be constructed along Willow Street where ready access to the community and the Montana Power facility will be available. Police protection will be provided by Rosebud County. If an office is required, it should be located at the fire station or in the commercial center complex.

CHURCHES — Two additional church sites are provided in the Plan. Both sites are in new residential areas. If new churches do not organize, they can be converted to additional residential lots.

HEALTH CARE AND LIBRARY SERVICES – Western Energy's primary responsibility for assisting with health care and library services is to provide sufficient space. A combination doctor and dental office is recommended as part of the commercial complex. Library services will be provided through a bookmobile from Billings, Montana. Therefore, no permanent space will be required for this service.

PARKS AND RECREATION – The plan for parks and recreation consists of the following elements:

- Landscaping of the existing park.
- Development and expansion of the proposed teen and community center.
- Development of new playfields, tot lots and parks within the open space.
- A bicycle path constructed throughout the open space and connecting the parks with major areas of the town.
- Additional facilities (a golf course and community recreation area), which are planned for areas beyond the limit of the planning area.

TRAFFIC

The thorough fare plan incorporates the existing street system and the development of new streets. The plan establishes three categories of thoroughfares which are:

(1) Major Thoroughfares .— which carry through traffic and are designed to move traffic with minimal congestion.

(2) Collector Streets — which connect one area of the community with another.

(3) Local Streets — which provide access to individual land parcels and are designed to encourage slower speeds.

Major thoroughfares are Main Street and Willow Street. Plans call for the termination of Main Street at the rail lines and the extension of Willow Street to the east across the rail tracks and to the west to connect with Highway 315. A grade separation will be required at the rail line crossing.

Collector streets are First, Second and Third Streets, which extend into areas of future development. Another collector extends south from the commercial center through the apartment area and into the single-family area. It will connect with Willow Street and Highway 315. First Street extends to the north and intersects with the extension of Third Street. Second Street serves the existing mobile home area and extends south into the proposed mobile home park. Third Street continues north of its present alignment and connects with Highway 315.

The remaining streets on the Plan are local streets. They are usually shorter than the other streets and are designed to provide access to individual lots. Pavement is narrow and curves are shorter to encourage slower speeds.

It is recommended that Highway 315 remain in its present location and that Western Energy and Montana Power petition the Highway Department to place the highway on a schedule for resurfacing and widening of the pavement. The present road is dilapidated in some areas and presents a safety hazard. An overpass is also recommended for the highway over the proposed road and rail line which will serve new mining areas to the west.

UTILITIES

Storm drainage, sewage and water supply are the major utilities to be provided in Colstrip. Several conditions should be given careful attention to insure smooth operation and functioning of these basic urban facilities. To this end the following recommendations have been made:

DRAINAGE –

(1) Western Energy should conduct a study to define flooding potentials of Armells Creek, particularly in that area within the community.

(2) A water storage basin should be provided in the existing park to handle any excessive drainage loads created by new development to the north. The basin, which normally would be dry, collects water during heavy storms and avoids construction of large drainage structures adjacent to the railroad down to Armells Creek.

(3) Utilize landscaping and the above basin principle in new development areas and in parks and open spaces wherever drainage may become a problem.

(4) Carry excessive surface runoff from the commercial center south to the Armells Creek tributary located in the planned open space within the multi-family area. The drainage should be handled in a subsurface system.

SEWAGE –

(1) The capacity of the existing lift station should be increased if new development south of Willow Street overloads the existing system.

(2) Additional sanitary sewer facilities should use pipe systems with flexible gaskets at joints to avoid infiltration.

(3) The lagoons planned for sewage treatment should be designed for up to 120 days' storage capacity.

(4) Western Energy should keep abreast of changing Federal requirements affecting sewage treatment and treatment discharges.

(5) Land disposal of treated effluent should be considered.

WATER –

(1) Western Energy should plan to provide a yearly water consumption of 400 acre-feet by 1980 — an additional 263 acre-feet of water per year over present supply of 137 acre-feet per year.

(2) Present areas served by four-inch mains should be replaced or at least paralleled with six-inch mains in order to maintain desired pressure and to meet fire department requirements.

ELECTRIC BUILDING
BUTTE, MONTANA 59701

October 9, 1972

Mr. Ben Wake
Administrator
Dept. of Health and
Environmental Sciences
State of Montana
Helena, MT 59601

Dear Sir:

In response to your inquiry made by Don Holtz as to specific dates that certain activities were undertaken by The Montana Power Company in the Colstrip area, I submit the following chronology of the activities and developments of our Colstrip project.

1969 - July - Negotiated the Technical Services Agreement with Bechtel Corporation to evaluate turbine generators and boiler additions to The Montana Power Company's system, initially planned for the Billings plant.

- Sept.- Placed an order for the first turbine generator set with General Electric Co.

- Dec. - Placed an order for the first steam generator with Combustion Engineers.

1970 - Mar. - Contracted with Bechtel Corporation for an engineering evaluation of potential coal fired steam electric generating sites throughout The Montana Power Company area. Previously planned addition to the Billings plant had been abandoned because of the local weather patterns, metropolitan development of the area and public attitude. The final Colstrip location was selected over 6 other sites in the Colstrip area, and 15 other locations on The Montana Power Company system, after complete environmental and economic evaluations.

Exhibit 4

- July - Surveys of potential cooling ponds in the general area - three on Stocker creek drainage - one each on Armells, Cow, and Pony creek drainage areas.

- Sept.- Soils and subsurface strata evaluation on four of the above sites by drilling 13 tests holes and digging 15 exploratory trenches.

1971 - Jan. - Colstrip site test hole drilling commenced for soil and subsurface strata evaluation.
- Installed a mechanical weather recording station and a recording hygrothermograph near the proposed site.
- Contracted with Western Scientific Services Incorporated to investigate weather records for the Colstrip area and establish a complete weather station at the location.
- Engaged W. L. Faith, Consulting Chemical Engineer, to evaluate meteorological data, plant design and equipment selection pertaining to air quality control.

- June - Expanded weather investigation and retained Montana State University through their Endowment and Research Foundation to establish long range meteorological program.

- July - Commenced drilling a 9,330 ft. test well to evaluate subsurface aquifers for possible water source for plant water requirements.

- Aug. - Design was finalized for the 350 ft. weather observation tower and erection was completed in November.

- Sept.- Began discussions with Montana State University through their Endowment and Research Foundation for development of a program to evaluate the effects of the Colstrip project on the existing ecosystems of the area.

- Nov. - Excavation for removal of coal underlying plant site commenced.

1972 - Jan. - Installed first air quality monitoring station consisting of an SOx, NOx sampling train, a high volume dust sampler, dustfall jar, Huey sulfation plate and a fluoride plate.

- June - First concrete poured - drilled caisson footings.

Exhibit 4

- Aug. - First surface placement of concrete grade beams on top of caissons.

In addition to above events, construction at the Colstrip site to date has consisted of:

Drilling a water well and installing a water system.

Erection and operation of a concrete batch plant.

Start of construction buildings - structures and placement of utilities for an office, warehouse, worker's change house and a maintenance building.

Building of access roads and subgrade for a railroad site.

Placement of the 840 yard pedestal base for Unit #1 turbine generator.

With the completion of all the caissons, Unit #1 foundations and grade beams, and site fencing expected by the first part of December, construction activity will be suspended until spring.

Yours very truly,

Carl R. Anderson

Air Quality Bureau
State Department of Health and
Environmental Sciences
Helena, MT 59601

ATTENTION: Don Holtz, Chief

RE: Draft Environmental Impact Statement Pertaining to the Colstrip Generating Plant

Gentlemen:

We have received and reviewed your draft Environmental Impact Statement dated October, 1972, relating to our application for a construction permit for the installation of equipment which may cause or contribute to air pollution. We have also reviewed your Draft Supplement, dated December, 1972, to that Statement.

Your statement refers to the ownership as a "joint venture" of The Montana Power Company and Puget Sound Power and Light Company. Actually, the parties are owners as tenants in common and it is technically not a "joint venture."

By letter to you of November 7, 1972, we submitted specific comments on your predictions of ground level concentrations of sulfur dioxide set out in the draft statement. A copy of our letter is attached as Item 1. We have also submitted specific comments on other areas of the draft statement by letter dated November 30, 1972, and December 29, 1972. Copies of those letters are attached as Items 2 and 3. Further, at the public hearing held by the Department in the Custer County High School auditorium in Miles City on January 5, 1973, representatives of both The Montana Power Company and Puget Sound Power and Light Company made oral presentations concerning the statement. A copy of the statement of Puget Sound Power & Light Company is attached hereto as Item 4, and The Montana Power Company's statement is attached as Item 5.

Exhibit 4

Now that we have completed our review of your draft statement and supplement, as well as those comments by others where copies have been furnished to us, we have the following additional comments on the statement and supplement as a whole:

1. Additional Information. In some instances, the draft statement tends to set out conclusions without stating the facts upon which those conslusions are based. For example, the social consequences discussed in the section of the draft statement dealing with the impact on the human environment seem to be predicated on the development of vast number of generating plants and mines and not on the construction and operation of the facilities for which application has been made.

We believe that elaborating on the facts pertaining to our proposed facilities would dispel what appear to us to be a number of erroneous conclusions. To further this end of making the draft statement more factual, we recommend that you consider the following preliminary studies and incorporate them in the statement as you see fit:

A. Meteorological Study

Montana State University is pursuing a long range meteorlogical investigation at Colstrip. A permanent weather station was established in 1971 and a 350 foot tower was erected to monitor wind and temperature up to that height. Higher altitude data has been obtained with balloons and aircraft. A full year of weather information has now been collected, and copies of that data have been submitted to your Department. Correlation between the tower information and the high altitude data is being pursued as well as their relationship with regional meteorlogical data. The Department may wish to supplement this study with data obtained from the National Weather Service at Billings, Miles City, or Sheridan, Wyoming.

B. Environmental Surveillance Study

Montana State University Agricultural Experiment Station has undertaken an evaluation of the existing conditions of the total environment in the area so as to establish a preproject base. The University is investigating the vegetation and soil chemistry, vegetative communities, vegetative growth (including fodder production which is of major concern to the local cattle industry), insect and animal communities and chemistry, surface and ground water chemistry, etc. Copies of the Experiment Station's "proposal" and "Preliminary Study Report" are attached as Items 6 and 7. The Experiment Station has prepared a study entitled "Range Types and Productivity of Two Study Areas in Southeastern Montana". This study was prepared for Western Energy Company, a subsidiary of Montana Power, and relates to certain areas described in that study. We have attached a copy of this study as Item 8.

Exhibit 4

C. Historical Values

An archaeological study was conducted by the University of Montana Anthropology Department under the direction of Dale Fredlund, State Archaeologist, during 1971. This study included all of the lands which will be part of the project during the development and early years of operation of the project. Arrangements are being made to expand the study to include lands that will be affected by mining activity in the later years of the project. A copy of the University of Montana's Archaeological Survey Report is attached as Item 9.

D. Community Planning

Ken R. White Company, Denver, Colorado, Land Use Planners Designers, and Architects has prepared a preliminary report on the development plan and program for Colstrip. This report investigates employment, population forecast, recommends housing plans, commerical facilities, community facilities, recreational facilities and utility requirements, and sets forth a general land use and circulation plant for the community and adjacent area. The final draft of this report has not yet been received, but will be sent to you when received.

E. Wildlife Habitat Utilization

This preliminary report has been developed for a limited area within the project by Ecological Consulting Service. The report essentially deals with a specific control area and is currently being expanded to include the entire project area. The initial summary of this activity is attached as Item 10.

F. Coal Mine Land Reclamation Research

The Montana Agricultural Experiment Station has conducted research in this area since 1968. The study has examined many aspects of reclamation requirements and has lead to the development of a successful reclamation program. A copy of Experiment Station's Research Report #20 is attached as Item 11.

G. Stream Flows and Water Data

The project as applied for will require approximately 8000 acre ft/yr, at rates up to a maximum of 8000 gpm. That maximum rate will be about 0.2% of the average flow rate of the Yellowstone River. Information pertaining to stream flows and other water data could be obtained from the U.S. Geological Survey, such as in their Special Publication 28, "Mineral and Water Resources of Montana", and also from the U.S. Bureau of Reclamation, the Corps of Engineers, and other governmental agencies. The applicants have retained Ecological Consulting Service of Helena, to more fully evaluate the water use and hydrology of the Yellowstone River, and what effects, if any, this minor diversion may have on the downstream characteristics of the river.

Exhibit 4

2. Need for Power. The draft statement makes reference to the need for electric power which necessitates the construction of the proposed project. No where in the draft statement, however, is this need quantified. Therefore, we have attached as Item 12, a summary of the projected loads, resources and deficiencies of the applicants through 1982 which should be included in the statement. This summary is developed on the same basis as data provided by the applicants to the Western Systems Coordinating Council for its annual publication "Summary of Estimated Loads and Resources".

3. Environmental Impact of Realistic Alternatives. In the section of the draft statement dealing with alternatives to the proposed project, nine alternatives are listed. Under the National Evnironmental Policy Act, upon which the Montana Act is modeled, the courts have indicated that "the range of alternatives that must be discussed in an impact statement is generally limited to realistic alternatives that will be reasonably available within the time the 'decision making' official intends to act." NRDC v. Morton, 2 ELR 20029 (D.C. Cir. 1972). Such a standard rules out at least the following alternatives which are discussed in the draft statement: nuclear fusion, magnetohydrodynamics, solar energy, wind, and geothermal energy.

Furthermore, the environmental impact of none of the alternatives set out in the draft statement is discussed. We recommend that the draft statement be supplemented to include such discussions.

4. Other Comments. There are a number of areas in the draft statement which could be made considerably more readable and understandable to the layman and scientist alike by adding the following additional sections to the statement:

a. Bibliography. The draft statement contains some conclusions which appear to be based on surveys or other statistical or research sources. For instance, on page 38, it is stated that "The future needs of the coal may be more urgent than our present needs for electricity." References to the sources for this and similar predictions would be very helpful to persons examining the statement.

b. Glossary. A glossary should be added defining such terms as "primary impact", "secondary impact", "pollution", and other similar words used throughout the draft statement. There are statutory definitions of these terms which appear to be different than the definitions which the drafters of the statement mean to attribute to the terms. For example, see the definition of "pollution" in the Montana Clean Air Act.

c. Appendix. An appendix describing the science of diffusion modeling would prove useful. Although the draft statement on page 12 states that diffusion modeling is "explained

Exhibit 4

more fully in the section dealing with sulfur dioxide", no such full explanation was found in that section. Readers of the statement deserve a full, descriptive explanation of diffusion modeling as it was applied to the analysis of the proposed project.

d. Maps. Illustrations, figures, maps, etc., offering a graphic statement for the laymen of Colstrip and its environs would be useful. The spatial relationship between this project and other features of the surrounding area would be enhanced through these visual aids.

Finally, we wish to point out that the applicants will be conducting continual monitoring studies of the air quality in the area both before and during the operation of the proposed project. These studies will be available to the Department of Health and Environmental sciences if it wishes to use them to supplement its own monitoring studies.

If you wish to review any of these comments with us, we would be pleased to meet with you. We hope that you will give these comments your fullest consideration and revise your environmental impact statement to incorporate them.

Very truly yours,

The MONTANA POWER COMPANY

GENERAL OFFICES
ELECTRIC BUILDING
BUTTE, MONTANA 59701

February 12, 1973

Daniel Vichorek - Technical Writer
State Department of Health
Helena, Montana 59601

Dear Mr. Vichorek:

The following discussion is offered in reply to your inquiries in your letter of January 12.

January 12 Letter

1 - Why was the Colstrip site most feasible?

Site selection for this project lead to the Colstrip area for environmental and economic reasons.

Environmentally, the Colstrip area is remote and development would affect fewer people directly; i.e., fewer residences, less roads and highways with less use. The weather patterns of eastern Montana are generally less confining than the more mountainous terrain of much of the MPCo.'s service area (detailed investigation has proven the weather patterns at the specific site selected to be acceptable). Existing land use levels would be upgraded by the proposed development; i.e., more people would realize more use from the energy available from this land than the values being received by very few people at its present level of use. Also, the lands disturbed by the mining activity will be reclaimed, and the extensive research over the past 5 years in WECo.'s area, indicates the disturbed land will be back in production in 3 to 5 years. The site adjacent to the town of Colstrip minimizes the travel and time of the operating personnel to and from work, as town facilities, including homes, would be provided by expanding the existing village.

Economically, all locations away from the mine area were subject to uncertain future freight rates for transportation of coal by rail, and also to possible shutdown from transportation labor strife that could interrupt coal deliveries. Also for this project, much of the energy transportation is accomplished

Exhibit 4

Mr. Vichorek

by displacement over existing transmission lines. But even a new transmission line installation has the advantage of known and practically fixed costs associated with it with a one time set investment required. Contrast this known cost with the unknown future freight rates for moving the coal.

2 - What was unfeasible about the other sites and might they be developed in the future?

The other sites considered were not as desirable as the Colstrip site in one or more of the reasons listed in #1, and were not necessarily found to be unfeasible. Each of the fifteen other sites around the state were considered to some degree, but not necessarily in great depth. An obvious unique local condition may have discounted a location promptly without serious consideration.

3 - What was discovered about the soil permeability and the water table at Colstrip?

Drilling throughout the Colstrip area finds the soils to be recent alluvium underlain by interbedded shales and lenticular sandstones overlaying the coal seams. The shales have little or no permeability. The first water zone is found in the coal seal, but potable water supplies throughout the area are taken from below the McKay coal seam; e.g., the Colstrip town shallowest water wells are completed at a depth of 350 ft., whereas the McKay seam at the plant site was at a depth of about 20 ft.

4 - Will any well water be used for any phase of the proposed project?

The only use of well water for this project will be from a 600 ft. Ft. Union well for water at the concrete batch plant. The well was drilled specifically for that purpose. A 9330 ft. Red River well was drilled by the MPCo. to test the availability of water for this project from underground aquifers. Testing of the Red River and Mission Canyon zones indicated deliverability restrictions and chemical composition requiring substantial treatment in order to make it usable.

5 - How much well water is available?

The Red River and Mission Canyon aquifers are practically unlimited in that they are being recharged from outcrops in the Big Horn Mountains and the Black Hills. Productivity on the test well reached 390 gpm from the Mission Canyon and Red River combined.

Exhibit 4

Mr. Vichorek

6 - What possibility is there of materials from the ponds reaching the water table?

None. The settling ponds will be sealed with bentsnite or some other impervious material to eliminate seepage into the ground. Methods and procedures to achieve suitable sealing are currently being investigated.

7 - What precautions will be taken against contamination of ground water?

No seepage into the ground or out of the pond in any direction, except for evaporation will be permitted as stated in #6.

8 - How tall will the cooling towers be?

The height furnished for your draft statement still applies; i.e., 65 ft. high x 48 ft. wide x 252 ft. long.

9 - What precautions were taken to prevent plume mixing between stacks and the cooling tower?

The low level cooling tower water vapor emission is about 600 ft. west of the stacks, which is generally upwind from the stacks.

The low level emissions of water vapor at a height of 65' with little thermal rise, will not mix with the stack emissions being released at 500 ft. with a significant thermal rise effect. In general, air movements will influence both emissions in the same direction which will tend to maintain the elevation difference. Appreciable lateral movement of the plumes will have to occur before mixing takes place, and such movement will dilute the concentrations of each plume. Mixing of plumes with sufficient concentrations of their individual components to have any detrimental effect will not occur.

10 - What is your estimate of monthly payrolls for each month at Colstrip project through the construction period?

See the attached schedule.

11 - Do you have any information on the drift potential from Colstrip on its (cooling water) ?

The cooling water will be fresh water, with some mineral carry over in the vapor, but these minerals will fall out within 200 ft. of the towers. Any fog formation is expected to be dissipated within the project property.

Exhibit 4

Mr. Vichorek

12 - Western Energy declined to cooperate in a study with the Fish and Game Department in 1969. Can you explain this?

WECo. was operating a limited mining activity in 1969 and had entered into a contract with the Endowment and Research Foundation at Montana State University to evaluate the flora and fauna in the area and research the reclamation needed for the mining area. As they had done with other mining companies, the Fish & Game Department approached WECo. suggesting a yearly fee of $1,000 to do some sort of a study of the Colstrip area. MSU was investigating and evaluating everything that the Fish and Game could offer. Government agencies are developed specifically to investigate actions, past, present and future, in unique definite fields of endeavor. I find it difficult to understand that the Fish and Game Department could not investigate the activity just because WECo. did not contribute $1,000/year.

MPCo. had not settled on the Colstrip site for the steam electric generating project in 1969. The choice was made in 1970. MPCo. was aware that a comprehensive study would have to be undertaken during the pre-project development to supply important base line data. Another agreement by MPCo. with the Endowment and Research Foundation at MSU extended their investigation and evaluation to cover a much greater area than just the mining reclamation agreement with WECO. A comprehensive wildlife study is also being pursued by a highly qualified local environmental consulting service. The necessary base line data will be established prior to the operation of these plants.

13- If studies indicate that the plant will be detrimental to the ecosphere, what will the applicant do to offset the effects?

Our extensive studies underway in the Colstrip area will establish what the ecosphere is. Continued observation will monitor changes in the base line conditions established by these studies. Changes identified as resulting from the project operation, will be investigated and evaluated.

Changes required to avoid detrimental effects from the project operation will certainly influence the project's future operation.

This project is being designed and developed to cause as little environmental impact as possible, but it will affect the environment. All actions do, including natural events. We will meet all of the requirements imposed by Federal and State laws and regulations for the operation of the project.

Exhibit 4

Mr. Vichorek

14 - Our booklet on how to conserve power was sent to you last week.

We continue to work on the balance of your questions. As soon as complete answers are developed, they will be sent to you.

Yours very truly,

Carl R. Anderson

Exhibit 4

The MONTANA POWER COMPANY

GENERAL OFFICES
ELECTRIC BUILDING
BUTTE, MONTANA 59701

January 31, 1973

Mr. Daniel Vichorek
Technical Writer
State Department of Health
Helena, MT 59601

Dear Mr. Vichorek:

I apologize for the delay in answering your letter of January 3, but your inquiries warranted complete answers and that has taken time. In reply, discussion of each of the questions you asked follows:

1. Has surveying begun on the two additional power lines?

No. Refer to my letter to Don Holtz dated December 29, 1972 included in your supplement to the Draft Environmental Impact Statement.

2. Has right-of-way for above lines been procured?

No.

3. When must survey be completed?

A July, 1973 completion of preliminary survey is necessary to allow sufficient time to evaluate environmental, engineering, right-of-way, and material considerations before construction which must commence in the spring of 1974.

4. About how far from Billings will substations be built?

Not yet located, but probably from 6 to 12 miles north in or adjacent to existing transmission line corridors.

5. How will substations be connected to the existing transmission facilities?

The substation will be the termination point of six lines. Two of those lines, one from Anacona and one from the Billings Steam Plant, are presently in operation. An additional line from the Billings plant will be put on existing double circuit towers. Another of the lines will be the Billings-

Exhibit 4

Great Falls line that will commence construction in 1973. The proposed Colstrip lines will be the last two lines terminating in this substation.

6. How much and what size lines will be required to make the connection?

How much line is unknown until the exact substation location is set. The six lines referenced in No. 5 are all 230 kV size. With some of the lines already installed and operating, environmental considerations suggest location to be so as to require installation of the least amount of new line.

7. When must survey and right-of-way be completed for the pipeline?

By January 1, 1974, assuming everything else is ready, and construction starts that coming spring.

8. Sketch on map of possible pipeline and power line routes.

Attached.

9. Detail flora and fauna along the routes, including how much crop land, range land and waste land?

Without precise routes, such detail would have to be so general and broad, the description would be impossible to ascertain with any precision, and would have little value.

10. How wide a right-of-way required for two parallel 230 kV lines?

Two hundred feet or less.

11. By two parallel 500 kV lines?

That size line is not part of this project, and The Montana Power Company has none of that size line on its system, but industry usage indicates up to 300 feet may be required.

12. What type of poles would be used for 230 kV lines?

Primarily two-pole X-braced wooden structures made with 50 to 60 feet poles. Some three-pole wooden structures required on angles.

Exhibit 4

13. For 500 kV lines?

Again, such lines are not part of the project and The Montana Power Company has none on its system, but industry uses metal structures primarily.

14. What are the specifications, route and projected completion date for the new Billings-Great Falls line?

The line will be a 230 kV routed from Billings via Judith Gap to Great Falls, and is scheduled for completion by November 1974.

15. Is this line related to the Colstrip project?

No.

16. What type and how many pumps will be required for each of the pipeline routes?

The design has not been finalized, and the pumps not selected. There will be a horsepower requirement of about 5000 horsepower and the pumps will probably be staged centrifugal.

17. Provide sketch of the development to illustrate the location of boilers, cooling towers and ponds?

The boiler and cooling tower locations were indicated on the maps submitted with our application for construction of equipment affecting air quality, in August, 1972. The 3-acre surge pond will be located about 1 mile north of the plant site, and the two settling ponds will be located approximately a thousand feet east southeast of the plant site, and will be approximately 30 acres in size. All ponds and equipment will be located on land presently owned by the Applicant.

18. What effort will be made to reclaim the land disturbed by the pipeline?

The normal reclamation procedure as pursued by The Montana Power Company in the past in the installation of its 1500 miles of buried gas transmission line will be applied to this installation. Backfill, compaction and proper re-seeding restores a pipeline right-of-way to its original appearance.

Exhibit 4

Answers to the rest of the questions you've asked in this letter, as well as the two following letters of January 12 and January 24, are being developed and will be sent to you as soon as the necessary information can be gathered and the questions fully answered.

I am enclosing a copy of our power conservation booklet that you requested in your January 12 letter.

A copy of Puget Power's comparable publication is also enclosed.

Yours very truly,

Carl R. Anderson

February 16, 1973

IN REPLY REFER TO:

John S. Anderson, M.D.
Director
State of Montana
State Department of Health &
Environmental Science
Helena, Montana 59601

Dear Sir:

In response to a letter from your Technical Writer, Mr. Daniel Vichorek, on the City of Colstrip, we are giving you the information we have in-house related to a subgrant where we funded manpower and equipment for Rosebud County. The City of Colstrip is in that County.

I am enclosing parts of the subgrant, giving you what data we have and information showing the budget page of what we are doing to assist them in trying to take care of any police impact in that area. It will also explain what they believe they can do from added taxes in the years to come after this funding year has ended.

The academic and professional background from the persons contributing information on this is from, what we believe, the expertise in that area, such as the District Judge Al Coate, the County Attorney, the Sheriff and the Juvenile Probation Officer. Since this grant was awarded, the City of Forsyth and the County of Rosebud have consolidated. I believe this will give them even better coverage from the additional manpower that we have funded to cover the impact of this Colstrip area.

Montana Power Company has asked assistance in law enforcement in Colstrip itself. As you know, this is not an incorporated city but a privately owned town. They are having problems with the local sheriff enforcing the law, as their director wants to limit what an officer can do inside the Colstrip area. We have tried to look at the entire county's problems in these matters. The other coal companies have given us what information they have of what they

Exhibit 4

believe their impact will be in the surrounding areas. The information I am sending you is the best that we have been able to come up with at this time. Some of the figures and data is from the State Planning Office here in Helena. Others come from the local law enforcement and criminal justice people.

I hope this will be of some help to you.

Sincerely,

BOARD OF CRIME CONTROL

Laurence L. Lytle

Exhibit 4

COAL INDUSTRY DEVELOPMENT IMPACT AREA

The estimated population increase in Rosebud County due to renewed COAL activity is projected at 700 families or about 2,800 persons. This is a county of 6,032 population; 5,042 square miles; with 281.75 miles of improved roads; 1,391 of unimproved roads and a taxable valuation of $10,559,000.00. It is a fifth class county with the city of Forsyth as county seat and a population of 1,873. Forsyth is a third class city. Within the county boundary is the Northern Cheyenne Indian Reservation, with the towns of Lame Deer, Birney, Ashland, Colstrip, Finch, Rosebud and Angela. These towns are prefected by the Sheriff and five officers. The city of Forsyth has a chief and three officers, three civilian dispatchers and two part-time dispatchers.

The COAL development is solely a private enterprise, and it is felt by local government that they can assume the added costs from a broader tax base provided by the coal industry. If funds are transferred from the ABM area to Rosebud County to assist for one year, local governments can then support the additional man-power to other needs within the Criminal Justice System.

It has been determined by Montana State officials that the COAL development sites will create a primary impact area which should receive planning priorities. A permanent industry will develop with an increasing and permanent population.

In requesting the transfer of funds from the ABM area, we have estimated a one year funding period from September 1, 1972 to August 31, 1973.

Exhibit 4

This section constitutes the heart of the grant application. It is the applicant's detailed statement of the project -- its aims, precisely what will be done, who will be involved and what results can be expected. Together with the project budget, it provides primary evidence for LEAA and the Governor's Crime Control Commission of the soundness of the project, the care and planning that has gone into its formulation, and the responsibility and qualifications of the applicant and others who will be involved.

SPECIAL REQUIREMENTS

Request for EQUIPMENT must include the following information:

Full description of present inventory
Is equipment an addition to or a replacement of present resources?
Full description of equipment requested, including make and model.

Request for TRAINING ASSISTANCE must include the following information:

Training background of applicants involved.
Full description of school, including agenda, course out-line, curriculum and instructors. Attach official brochure whenever possible.

THIS NARRATIVE SHOULD FULLY EXPLAIN ANY ITEM NOT COVERED FULLY ON BUDGET PAGE.
Use Continuation pages if necessary

The Following program is designed to alleviate the pressure on law enforcement in the 16h Judicial district caused by the sudden influx of people into Rosebud County.

Personell:
Deputy probation officer to hired from federal funds.
Deputy Sheriff to be hired from federal funds.
Secretary to be funded from federal funds, services to be shared jointly by Probation office and the County Attorney's office.
Judge Alfred Coate will act as the Project Director and will devote 10% of his time supervising the project.
Irvin Zeitner, Chief Probation officer will devote 20% of his time supervising and training the new probation officer.
Sheriff Andy Schulenberg will spend 20% of his time in the supervision and training of the newly hired deputy sheriff.

Travel:
20,000 miles per year to be traveled by the deputy probation officer needed from federal funds. Computed at 12c per mile.
Rosebud county will maintain and support the new or additional patrol car to be purchased. Computed at $200.00 per month.

APPLICATION DISTRIBUTION:

For Units of Local Government

White copy - applicant agency
Green copy - Region Council
Gold copy - Region Council
(to be forwarded to Crime Commission)

For State Agencies

White copy - applicant agency
Green copy - extra
Gold copy - Governor's Crime Control Commission

Exhibit 4

Equipment:
Patrol Car, needed for additional deputy to be hired that will be stationed at Colestrip, Mt.
Two Mobile Radios 4 frequencies, Model MT74TFN 100 Watt including installation. One to be installed in the additional patrol car and one to be installed in the deputy probation officers car.
Graphic Camera Kit, needed equipment by the Sheriff's office.
Psychological Testing kit, usefull instrument needed by the Juvenile Probation office.
Two WV-o33v CCTV/VTR Monitoring cameras.
Two WV-7063P Video Monitors, this equipment to be used to be able to monitor the jail at all times. The jail is used jointly by the Sheriff and the City Police.

Operating expenses:
Installation of monitoring equipment and including the necessary wire.
Line rental charges to Mountain Bell Telephone Co.

ATTENTION: Mr. Don Holtz

Gentlemen:

We understand you do not have copies of Stearn's "Air Pollution" which we referred to in our statement at the public hearing in Miles City on January 5, 1973.

Enclosed are copies of Pages 535 to 549 from the Second Edition of Volume III of that text. Although this chapter discusses the water quality aspects of air pollution control, the references to the use of wet scrubbing systems for fluoride control, especially Pages 540 and 541, make it clear that this equipment can be expected to minimize residual fluoride emissions from our proposed operation.

Also enclosed is a copy of Part 1 of Chapter 5 from Volumn I of the same text. We referred to this in our discussion of radioactive emissions.

Finally, we are enclosing copies of a chapter entitled "Environmental Radiation From Pressurized Water Reactors" from "The Environment and Nuclear Power" by Dr. James H. Wright, Director, Westinghouse Environmental Systems Department. Pages 14 and 15 give information on naturally occurring radiation which we believe helps to put any expected radiation effects from our Colstrip plants into proper perspective.

Very truly yours,

D. T. Berube
Thermal Generation Engineer

Dear Mr. Vichorek:

I have your letter of February 6 concerning the projected population increase in the Colstrip area, and I am pleased to offer pertinent information.

We have been in touch with the schools in the Colstrip area and our supervisors have discussed with school personnel the building and curricular expansion for their elementary and secondary schools.

We have made our School-Community Assistance Process available to school officials, and we are prepared to offer professional assistance in every way possible. A description of the process is attached for your information. The School-Community Assistance Process is under the direction of Dr. L. E. Scarr, Assistant Superintendent in my office.

If I can be of further assistance, please let me know.

Sincerely,

Dolores Colburg

Dear Mr. Vichorek:

Once again I apologize for the delay in answering the rest of your inquiries of January 3rd and 24th. The following discussion is offered in reply to the balance of your questions.

January 3 Letter

19. Why is the power plant needed?

This Colstrip Project is needed to supply the electrical energy required by the customers of M.P. Co. and PSP&L Co., and other citizens of the Pacific Northwest. That customer requirement is based on the projection of past usage adjusted for known changes. The historical peak and energy loads for the M.P. Co. are attached, as well as the projected loads, resources and deficiencies for M.P. Co. and PSP&L through 1982. The projection, which was previously presented to your department with our comments on your Draft EIS, shows the increasing requirements and deficiency and the need for additional electrical energy.

The M.P. Co. generation, together with purchased power, served the 1971-72 winter peak load with 124,000 kW to spare. But 144,000 kW of power purchased in 1971-72 will not be available to M.P. Co. by the winter of 1975-76 because the electric suppliers now selling us this power will need it for their own customers. An additional 27,000 kW of purchased power will be lost to M.P. Co. by the winter of 1976-77.

The M.P. Co. load historically grows at approximately 5% per year. We see nothing which will substantially change this. If the Colstrip units are not constructed, M.P. Co. will be 174,000 kW deficient by the winter of 1975-76. M.P. Co. will be deficient by 246,000 kw by the winter of 1976-77.

Exhibit 4

The increasing requirement for electrical energy is the result of our expanding productivity which has made us the greatest industrialized nation in the history of mankind. The use of electrical energy has also increased our life expectancy, decreased our work week, and allowed us to develop the casual pleasures of our life style, such as TV, radio and light to increase our productive hours and expand our horizons. Energy protects us from the elements and adds to our security. Electrical energy is truly a necessity in our modern lives.

There is no alternative to the Colstrip Project. No other technically proven source of electrical energy is possibly achievable in time to supply the electrical needs of the M.P. Co. customers. The only technically proven alternate energy source available in the size of this project is nuclear fission. That source would not only be much more expensive, but could not be constructed by 1975. Eight to ten years are required for such a nuclear project, and there would still be much environmental concern by the public.

Other sources of energy are alluded to by uninformed persons, but such alternatives are not available. Such sources mentioned are wind, solar, organic waste, geothermal and MHD.

Wind power has been used for pumping water wells and charging batteries throughout the world for years. These are sporadic uses and adaptable to the caprice of nature. 700 MW of reliable sustained electrical energy could not be developed with such a system.

Solar energy sites are limited to 35° north and south of the equator. Stronger and more continuous sunshine is available in that area. Even there, with continuous sunshine for reliability (which of course, is not available) a 700 MW output would require about a 70 square kilometer collecting area with a collecting efficiency of 10%. (See Scientific American Vol. 224 No. 3 Sept., 1971, p.67) Montana is not geographically located to even consider such an installation.

Decomposition of organic waste holds interesting, but limited possibilities for future power generation. The city of Missoula is an example of the current technology of such a process. That metropolitan area utilizes the methane generated in their sewage treatment facility, and realize only enough gas to partially power a 187 kW electric generator. Their average electric load in 1972 was about 1800 kW per day, ten times the usable methane realized from their waste processing.

Geothermal is also of limited applications. Such development is confined to unique geological locations where the earth's heat is near the surface, such as the Geysers in California. That prime geothermal project supplies only 302 MW of electric capacity, less than

Exhibit 4

one half of the proposed Colstrip Project, and it has been under development since 1956 when the well drilling began in earnest.

The sources listed above are just being investigated or developed, but have hardly progressed beyond the laboratory pilot plant stage. Even MHD (Magnetohydrodynamics) utilizing clean burning natural gas in Russia, which is a rapidly diminishing energy source in most parts of the world, has not been developed beyond 25 MW of capacity.

Coal is the most realistic energy source available for conversion to electrical energy at the present time with known technology. Other fossil fuels are in short supply whereas coal is an abundant resource. Nuclear fissionable material is also limited in supply at the present time, although that will be resolved when the FBR is developed. Developable hydro sites are limited, and such projects have limited public acceptance.

The proposed Colstrip Project is truly the only technically proven and possibly achievable source of electrical power required to supply the increasing demand for electrical energy by the customers of M.P. Co. and PSP&L .

20. Is the demand for power growing faster than the population of Montana?

Yes. For example, the residential customers of The Montana Power Company increased from 131,203 in 1961 to 151,334 in 1971, about a 15% increase. Whereas the individual residential customer average usage increased from 4,177 kilowatt hours per year to 6,032 kilowatt hours per year in the same period of time, about a 44% increase.

21. What accounts for this increase?

One of the classes of customers whose use of electricity has increased the most has been the farmer. Farms now use as much electricity as many small industrial concerns. Television has been one of the larger contributors to the use of electricity. Lights of all kind contribute less to the growth of electric demand than many other appliances, such as ranges and water heaters.

The previously referenced residential increase has been lightening the physical work for the homemaker and increasing leisure time, brightening evenings for more reading and other pleasures, as well as enhancing law enforcement, increasing safety on the streets and highways. But the residential use amounted to only about 20% of the total sales of The Montana Power Company in 1971. The balance of the electrical sales provided jobs, goods, services and conveniences in our commercial and industrial world. Some of that use was for environmental improvement, and more will be required for that use in the future as additional towns install the sewage treatment equipment required by

recent federal law, as proper disposal or recycling of the ever increasing amounts of solid waste is developed and as more emission sources are controlled to improve air quality. With reference to that, about 30,000 to 40,000 kW of the capacity of the Colstrip generation will be consumed at the plant just to operate the air quality control equipment being installed.

22. Use of power by percentage in Montana to industry, home heating, aluminum smelting and all other uses?

The state totals are not readily available, but those figures for The Montana Power Company system in 1971 were:

Industrial - 2,178,169 Mwh
Home Heating - insignificant *
Aluminum Smelting - 0
All other uses - 2,392,116 Mwh

* Only 1,483 dwelling units are equipped with electric heat on The Montana Power Company system, and many of them are seasonal dwellings, such as summer cabins or ski resorts. The overall electric consumption for home heating is very small since natural gas has more than a 95% home heating saturation in the company service area. Other fuels for home heating include oil, coal, propane, wood and hog fuel.

23. Power exported out of state will be delivered where, and will be used for what?

The Montana Power Company system is an integral part of the North west Power Pool and the Western Systems Coordinating Council as described by Mr. John Ellis of Puget Sound Power & Light Company in his presentation to the board at the public hearing in Miles City on Janua 5. We presently have 230 kV ties south to the Bureau of Reclamation and Pacific Power & Light at Yellowtail Dam, southwest near Lima to Utah Power and Light and Idaho Power Company, and west to Bonneville Power Administration and Washington Water Power Company at Anaconda ar Hot Springs.

The power produced at Colstrip Units #1 & #2 largely will be consumed in Montana. Exported power will flow through The Montana Pow Company system to any one or all of the interconnected systems at various times with Montana Power Company and Puget Sound Power and Light Company owning and controlling the output of this project equall for each unit. The power will be used to satisfy the customer require ments of those interconnected utility systems, and will be a necessary part of total supply required to maintain the integrity and reliabilit we all expect and demand of our electric service.

Exhibit 4

24. What accounts for the increased demand for electricity in the area where the power will be delivered?

Generally the same things that increase the demand in Montana as described in answers 19, 20, & 21, but compounded by greater population increases in many areas in the Pacific Northwest than the increase experienced in Montana. People migrate to and are productive in the places where the most opportunity and the greatest number of jobs are available. Montana's limited growth indicates a lack in those.

25. What are the economies of hauling coal to the generating plants near the out of state load centers vs power transmission from mine-mouth generating plants?

The economies are unique with individual company situations as shown by the fact that coal continues to be shipped to load centers even for new plants being built in the Midwest by some companies. And others, namely Puget Sound Power & Light Company and Montana Power Company, are investing in mine-mouth generation.

The power produced at Colstrip Units #1 & #2 largely will be consumed in Montana. System Montana flow studies indicate that the only transmission necessary for the project under application would be lines wholly within Montana. The project will not require new transmission westward outside the State.

From a regional reliability standpoint, construction of the generating plant and transmission lines in Montana will significantly improve the load flows within the coordinated network of the Western Systems Coordinating Council, strengthening this traditionally weak portion of the system. With the generating plant at Colstrip, load flows eastward into the State will be reduced and at certain times reversed.

Bonneville Power Administration (BPA), the Washington Water Power Company (Water Power) and Montana Power Company have interconnections in western Montana. Puget Power has interconnections with BPA and Washington Power in western Washington, thus Puget Power's share of the project output will be furnished to Puget by displacement through the company's interconnections with BPA and Washington Water Power. In other words, Puget Power's share will be consumed by customers of BPA and Water Power in the eastern portion of the Northwest Power Pool while an equivalent amount of power will be supplied to Puget Power in western Washington. This procedure eliminates the need for interstate transmission line construction and reduces the line losses of the involved utilities.

With the only transmission required located in Montana, clearly the evidence overwhelmingly favors transmission as the alternative to hauling the coal in this instance. The economics of these

alternatives as applied to other generating plants would, of course, vary with the capacities, plant locations and load locations involved.

Also, definite advantages do exist with an electric transmission line investment, compared to shipping coal. The energy transportation over the electric transmission line would not be exposed to future escalation of freight rates, and the possibility of interruption of energ delivery caused by transportation labor disputes would be eliminated.

January 24 Letter

1. Have you definitely decided on venturis?

Yes.

2. What leads you to believe the venturis will perform up to par over the life of the plant?

The EPA set their recently adopted "stationary new source emission" standards on the fact that scrubber technology was proven, as Dan Berube pointed out in his statement in Miles City.

Also, Bechtel Corporation, the engineering contractor on the Colstrip Project, of world-wide reputation, organized a research team for the investigation of scrubber technology. They concluded venturi scrubbers are feasible and in fact developed, and recommended they be used on this Project. In addition, the M.P. Co. engineering staff investigated this problem in depth and visited numerous scrubber installations throughout the country. Their findings and observations confirmed Bechtel's results and further recommended the use of venturi scrubbers. The expenditure of $20 - $25 million is never done lightly. Every check and evaluation achievable has been pursued prior to committing that amount of money for this equipment.

I would also like to point out that the plant operation is entirely dependent on suitable scrubber performance. The plant cannot be operated without the scrubbers in service, as there will be no by-pass installed. If the scrubbers plug off, the combustion gases cannot be exhausted.

3. Other reports on the operation of venturis on other plants similar to the Colstrip development?

Attached is a review of "the State of the Art" of scrubbing, summarizing the development of scrubbing. We have reviewed many technical reports on other installations, as you no doubt have. We are currently investigating operating performance of this unique venturi application with a pilot installation on the J. E. Corette unit at the Billings Plant for which we have received authorization. Design parameters and performance characteristics developed from the operation of this pilot installation will be the basis for building the Colstrip facilities.

Exhibit 4

4. Have you checked into the Krebs-Elbair type scrubbing device?

Yes. It was our decision that if particulate only had to be removed, such equipment could possibly have been used. A limited amount of SO_2 would also be removed, but the capacity and flexibility of this device is much more limited than the more sohpisticated venturi selected. The Krebs could possibly remove up to about 20% of the SO_2 with the Colstrip ash characteristics. The venturi, equipped with delay tanks and utilizing the ash for scrubber liquor, will result in higher SO_2 absorption rates up to 40%. A review of this scrubbing technique is being developed and will be sent to you when done, probably this week.

5. Are the concentrations of sulfur, fluoride and other pollutants uniform throughout the coal seam?

The analysis of various coal samples from the Colstrip seam show minor variations in the sulfur and fluoride content. The coal has also been tested for mercury. Test results have already been submitted to the Department of Health. The majority of the sulfur occurs as pyrite nodules, deposited in fractures in the coal and as fossil replacement. Incidentally, the larger pyrite nodules are rejected by coal pulverizers in the Corette plant, and the Colstrip plants will be equipped with similar pulverizers.

6. Which trace elements will be looked for in the West Associates analysis?

The elements being investigated are arsenic, boron, beryllium, cadmium, chromium, fluoride, germanium, mercury, manganese, nickel, lead, selenium, vanadium, yttrium. The study is not yet completed.

M.P. Co. has now entered into an agreement with the Endowment and Research Foundation at MSU to investigate the same 14 elements in Colstrip coal. This program is just starting. Some core hole coal samples have been collected. Additional sampling will establish a proper pattern for full evaluation of the coal deposit, both laterally and vertically. This information, in conjunction with West's information on disposition during combustion, will lead to positive identification of emissions.

7. When will the results be available?

West Associates have some data that is being evaluated, but is not available until the project is completed, which should be during the last half of 1973.

The MSU investigation is just starting. Assuming no delay in establishing techniques and procedures, data should start becoming available by mid-year.

Exhibit 4

8. What other facilities will be built for the construction workers?

A construction camp is being erected by M.P. Co. for construction workers. The camp design has been reviewed and approved by the State Department of Health, Environmental Services Bureau. The camp will be equipped with a kitchen-dining facility that will handle 300 people, and which can be expanded up to a capacity of 500 people. There is also a recreation hall included in this camp.

A 20 unit camper area, including a central washroom with showers, toilets and laundry facilities is also being developed.

Also, M.P. Co. is developing a 200 unit mobile home park for construction workers. The town of Colstrip is also being expanded by Western Energy Company. Additional homes are being built, and the mobile home park is being expanded. The town development is described in detail in the enclosed brochure summarizing the Ken R. White planning group's recommendation. The town sewage facility was recently expanded by a local special improvement district to accommodate all of the present and planned development. An approved landfill solid waste disposal area is also available.

9. What slimicides would be used in the towers at Colstrip?

The precise slimicides have not been selected, as the potential problem has not been evaluated at this time. Any chemical treatment required will certainly be accomplished with acceptable and approved chemicals or slimicides.

10. How will slimicide bearing water be treated?

We do not know at this time. Treatment will depend on the amount and type of slimicide required.

11. How will the water soluble portions of the ash be prevented from reaching the ground water?

Answered previously in question #6 of your January 12 letter.

12. What is the current status of construction at the plant site?

No activity has been underway since last December, when the balance of the concrete footings and foundations was poured for Unit #1. Steel is expected to start arriving early this spring.

13. When will the full year's meteorological report be available?

The total year summary is expected within a month and will be sent to you as soon as it is received.

Exhibit 4

Answers in previous letters cover the balance of your questions asked in the last paragraph of your letter of January 24. If additional information is required, please let me know.

I believe this completes the information required in your three letters with the exception of detailed design and operating specifications of the plant requested in your January 24 letter. As discussed with you, this information will be developed directly with Don Holtz by our engineering department.

Yours very truly,

Carl R. Anderson

RECEIVED
JUL [illegible]
ENVIRONMENTAL SCIENCES
DIVISION

COMMENTS OF:

THE ENVIRONMENTAL POLICY CENTER

ON

THE DRAFT ENVIRONMENTAL STATEMENT

ON THE PROPOSED MONTANA POWER COMPANY

PLANT AT COLSTRIP, MONTANA

Submitted by:

Bruce C. Driver

Exhibit 4

Exhibit 4

The Environmental Policy Center believes that the Draft Environmental Impact Statement (hereafter known as the Draft) does not adequately measure the environmental impacts stemming from the construction and operation of a 700 mw electrical generating plant at Colstrip, Montana. We recommend that another draft statement be circulated for public comment prior to the preparation of a final statement.

Exhibit 4

On page one of the Draft it is said that mine mouth plants are favored, "at least from the owner's standpoint." What about the standpoints of the citizens of Montana whose value preferences, as mirrored in the policy statements of section 3 of the Montana Environmental Policy Act (Montana Statutes 69-6503), are those which the state government is charged with implementing in its actions? In the Northern Plains there is very great risk that decisions made by private enterprise in a climate of indirect governmental subsidy and articulated in dollars and cents figures will be allowed to be determinative of the Region's future. The very real but intangible preferences of the people of the Region may be given short shrift. Nowhere in the Draft is there any example that the State has attempted to measure citizen feelings about the precedent-setting Colstrip Plant and related development. It may be that much useful information is being elicited by the comments to the Draft and attendant public hearings. However, in light of the complexity of the suggestions of the North Central Power Study, Wyoming-Montana Aqueduct Study and the Colstrip Plant's relationship to the concepts of these two studies, it is recommended that the State allow more time to pass before a decision be made on the question of permitting construction of the Plant. During this time citizen preferences ought to be more rigorously examined, the results of such examination appearing in a second draft statement to be oirculated before preparation of a final statement. The extra time will allow citizens to more fully acquaint themselves with the meaning of the decision regarding Colstrip.

Also on page one, the Draft mentions Venturi Scrubbers, stating that, "There is evidenoe that the venturis will also remove most fluorides and trace metal compounds." In conjunction with the material on pp. 18-20 of the Draft pertaining to trace elements in the coal, this halting statement leaves us with no confidence that the State is aware of the problems which

can result from the buildup of trace elements in the environment or, if it is aware, that it is in a position to control these problems. In light of the spotty history of operation of venturis, we recommend that the State complete further research into the effectiveness of venturis in controlling trace elements which could arise from the coal seams to be mined in order to supply the Colstrip Plant with fuel.

The Draft makes only passing reference to the end use of the power to be generated at Colstrip. That much of the electricity will be consumed in load centers outside the boundaries of Montana should be of concern to those citizens of Montana who have a stake in the continuing availability of those aesthetic amenities, the lack of which in centers such as those to which the electricity from Colstrip may be sent, attracted them or their forefathers to Montana. That we live in a federal system in which much commerce is interstate will not mitigate the sting in the minds of many Montanans if most of the benefits from power development in Montana flow to private owners of capital and consumers outside the boundaries of the state, whereas most of the costs are imposed on Montana. At the very least the State ought to provide a more detailed picture of end-use of Montana resources in the "Description of Proposed Action."

We would like to see greatly expanded treatment of the pipeline transporting water to the Plant from the Yellowstone. This most cursory explanation does not let the public know what the size of the pipeline is to be or what the effects on the Yellowstone are of the withdrawal of the given amount of water, to name but two of the deficiencies which must be remedied.

In failing to discuss the strip-mining for coal and attendant problems of land reclamation necessitated by the Colstrip Plant, the State has made a serious mistake. If the Plant is permitted to be constructed, coal will be strip-mined, regardless of the fact that a later environmental impact study

on strip-mining may indicate that satisfactory land reclamation is unlikely. Construction of the Plant is the cruoial event foreclosing honest consideration of future environmental impacts because of the pressure which will be exerted to allow coal to be strip-mined to fuel a plant which has already been certified and constructed. A revised draft must contain information on land reclamation technology and its physical ability to bring about satisfactory reclamation in the Colstrip area. Furthermore, the economics of reclamation and the institutional enforcement mechanisms of the State should be examined.

Section 5, Construction and Location, on page 3 of the Draft demonstrates that the State has little knowledge of or control over populations fluxes associated with construction of the Plant and thereafter. Where will the 800-900 men required for construction and their families live? Who will provide services for them? And what will happen to these services after these men and their families depart? The State must answer these questions before it makes a decision on the Plant. If it cannot answer them or if it allows private actions to determine the answers on an ad hoc basis, Montanans can be sure that they are on the road to seeing their state Appalachianized.

Page 8 of the Draft raises several points which are not effectively treated in the Draft. Under D., "Historical Values", the statements are made that "The archaeology of this area is not well known. This portion of Montana may contain a great wealth of historically significant archaeological material." The logical conclusion of this is to conduct a reconnaissance of the area believed to be affected by the Colstrip Plant and the supplying coal mines before permitting the construction of the Plant.

Regarding E, "Recreation", the importance of the Colstrip area and surrounding country to the national public should be stressed. Although not spectacular country like that found in the national parks and wilderness areas of Western Montana, Southeastern Montana is the epitome of the great rolling plains and, as such, occupies an important niche in American cultural history.

To the urban easterner, the Indian and ranching cultures which have developed on these plains have values of their own, apart from any aesthetic amenities offered by the wilder areas of Western Montana. Further examination should be made of the national demand for the recreational amenities offered by the Colstrip and surrounding areas before even part of the area is committed for power development.

The section on Meteorology leaves something to be desired in our opinion. The major east-west storm track across the United States does not pass through the center of the state. No major storm track crosses any part of Montana or, for that matter, anywhere near the state. Low pressure systems from the Pacific Northwest generally follow a trajectory which takes them southeast from Washington or Oregon across Utah into Colorado, New Mexico and, sometimes, Wyoming before they turn on a more easterly path. Storms not originating in the Northwest may form anywhere along an arc from Colorado through Texas, the Gulf and up the East Coast, but only rarely will a major storm originate in Montana. This is why precipitation levels are low and why no satisfactory, eccnomically feasible technology of land reclamation for arid Northern Plains lands has been developed.

On page 12 of the Draft, it is said that "Emissions are expected to drift to the east." It is probably true that winds in the Colstrip area blow from west to east more than in any other direction. However, strong and prolonged northerly and northeasterly winds associated with arctic air masses may interrupt the west to east pattern for a substantial portion of the fall and winter months. And in the spring and summer, a southerly air flow may predominate for lengthy periods of time. We suggest that the State should have a better grasp of wind conditions and their variability before allowing construction of the Colstrip Plant.

Exhibit 4

Exhibit 4

Regarding "Impacts Other Than Emissions" there is a disturbing reliance on future willingness of Montana Power Company to do what is necessary to avoid damage to the environment. For example, on page 25 of the Draft, "The applicant has indicated that they will selectively landfill the ash if groundwater purity is threatened." Later, "Aeration equipment can be easily added...if an odor problem arises...." Will the state require it? The history of voluntary compliance in the utility industry is not such as to permit us to have confidence that action will be taken when necessary. The State must be able to assure its citizens that it has the power to assure that proper steps will be taken well after the construction of the plant is completed and when power is being produced. Who will monitor the Plant on a continuing basis? What are the sanctions which can be imposed if there are violations of state and federal law and regulations? It may appear that the answers to these questions are not the subject of an environmental impact statement. However, such information is vital and, indirectly, has an impact on the natural environment. Maybe this is why federal NEPA statements now carry extensive information about monitoring, lease forms, stipulations, etc.

On page 26 there is no indication that the State knows what the effect of alternative modes of sewage treatment are. If the state did know, it might have decided that a decision should not be made only on the basis of "simplicity of operation and costs" but also on health and welfare criteria.

We have the feeling when reading the section on "Impact on the Human Environment" that the State does not understand the nature or the magnitude of the problems involved. Planning may offset some of the more grotesque dislocations which mining can produce in a region. But no amount of planning can stop long term deterioration of a region when the capital responsible for

the boom departs, unless there are guarantees that the mining industry or the state pay the costs of relocation and maintenance of public facilities. These costs are likely to be staggering. An eroded tax base in the mining region will not help the State raise the money. Diminished agricultural viability of the land which is as well unable to sustain a tourist trade are but two of the ways in which the wealth of a region is diminished by mining. The source of future revenues to be used to mitigate the deleterious impact on the human environment must be the Montana Power Company and other private investors. Financial guarantees should be exacted before construction of the Colstrip Plant is permitted.

In Alternatives to the Proposed Action, the State is faced with discussing alternative means of supplying power to regions most of which are outside of Montana. The discussion on pp. 34-36 of the Draft talks in very general terms and in extremely cursory fashion about alternative energy sources. We submit that the discussion bears no relevance whatsoever to the question at hand. We realize that it may be irregular for one state to talk about alternatives for load centers outside its boundaries, but due to the nature of Montana Power Company's plans for the Colstrip facility, it is this question which should have been discussed.

In addition to erroneously framing the issue for discussion, the State has come forth with a most superficial analysis of alternatives. What would be the actual effect of not constructing the Colstrip Plant? Exactly who, if anyone, may suffer from the failure of this plant to produce electric power at certain times in the future? How many megawatts would have to be produced at some other power plant? How can we know what the parameters of an alternatives discussion are if we do not have some numbers to go on? A revised draft of the environmental statement must answer these questions.

Exhibit 4

Solar energy is more than in the research stage at this time. In fact the equipment necessary to collect and store energy from the sun for heating, air conditioning and ventilation in residences is in the nature of plumbing, not space age technology. Insofar as the electric power generated at Colstrip may be for these residential purposes, solar power would be a feasible substitute for Colstrip power were it not for the fact that much of this power appears to be headed for the cloudy Pacific Northwest, one of the few areas of the United States where solar power for residences may not be viable at this time.

Geothermal resources present much less of an "unknown" at this time than does satisfactory land reclamation technology in the Northern Plains. One study, "Geothermal Energy", prepared by Walter Hickel and staff for the National Science Foundation presents the following table entitled "Geothermal Energy Resources Potential":

	1975	1985	2000
Power (thousands of mws)	0.75	132	395
Electrical Energy* (millions of mwh)	5.913	1041	3114
Oil Equivalent** (millions of Bbls/day)	0.024	4.213	12.60

*90% load factor

**3,412 BTU/KWH and 5,800,000 Bbl of oil used at 40% conversion efficiency

These are estimates made by a Panel on Geothermal Energy Resources, U.S. Dept. of the Interior, August 1972. They represent the amount of electric power possible from geothermal sources at certain times in the future. Data from this report indicate that geothermal power could be considered as an alternative source of power for the Pacific Northwest.

Exhibit 4

Missing from the section on Alternatives is consideration of the alternative of conservation of energy. A new draft environmental statement might point out, with reference to the Office of Emergency Preparedness's study, "The Potential for Energy Conservation," October, 1972, that there are substantial savings available in industrial, residential and transportation sectors of our energy-using economy from conservation measures. The OEP study suggests energy conservation measures can reduce nationwide energy demand by as much as the equivalent of 7.3 million barrels per day of oil by 1980. How relevant the potential savings from conservation of energy measures suggested by the OEP Report are to the question of whether or not to permit the construction of a plant at Colstrip cannot be known in the absence of more data regarding end-use of the power. Assuming that most of the power will start to flow to load centers in the Pacific Northwest in the mid-1970's and that the power will be used primarily for residential and industrial purposes, the State might address itself to such measures as more efficient home insulation and the use of taxes to encourage more efficient energy use in industries of the Pacific Northwest. These are but two of the mid and long-term measures suggested in the OEP study as real alternatives to the continuation of the construction of power plants to meet growing demand. Of course the State of Montana has no direct control over whether or not conservation of energy measures are implemented in those load centers to which power generated at Colstrip will flow. Yet the fact that these alternatives exist provides ample justification for the refusal of the State to allow its lands and culture to be disrupted in order to supply areas which have not implemented conservation measures. The State may want to withold permission for the construction of the Plant at Colstrip pending an examination of implementation of conservation and other alternatives measures in the load centers to

Exhibit 4

which Colstrip power will flow. In any event, further examination of all alternatives should be made. The results of this examination should be published in another draft of the required environmental impact statement.

Exhibit 4

CONCLUSION

While we believe that the State has made an admirable beginning of the arduous task of examining environmental impacts, we must underline the fact that the Draft is only a beginning. The Draft simply is not a satisfactory document on which to base a decision regarding the construction of the Colstrip Plant. We have indicated where we think the Draft is deficient. We think that the procedure to follow is circulation of another draft in which these deficiencies can be remedied.

Perhaps if the Colstrip Plant were but one, isolated plant, we would not be so concerned that the State comply rigorously with the Montana Environmental Policy Act. But, whether or not the North Central Power Study, as such, is defunct, pressures for development on an enormous scale of Northern Plains coal and power facilities are destined to increase to levels which will be hard to resist unless the State is fully aware of the environmental problems involved. State governments in the Northern Plains will get buried in the rush of private and federal governmental interests to develop the riches underlying the Plains regions, unless these States begin early to examine the complex environmental and social problems of development. States must learn to extend their examinations into problem areas heretofore left to the federal government, such as alternatives to conventional power plants supplying multi-state areas. We realize that this Draft does not represent the total effort of the State of Montana regarding electric power production or strip-mining in Montana. Nevertheless, because of the importance of the Colstrip Plant decision, we feel strongly that the State should more fully examine the variables affecting this decision in another draft.

7) inadequate data throughout upon which to judge the Draft, and hence offer comment.

Comments upon specific portions of the Draft Supplement follow.

Exhibit 4

Fluorides

According to the DS, the proposed Venturi scrubbers for the Colstrip generating plant should remove 97-99+ percent of the fluorides from the gaseous and particulate emissions of that "proposed plant" presently under construction. The Department of Health and Environmental Sciences utilizes a report from the Stauffer Chemical Company to demonstrate the efficiency of Venturi Scrubbers in removing fluorides from the Stauffer operation at Ramsey, Montana.

A 1972 study by the personnel of the University of Montana Environmental Studies Laboratory of fluoride accumulation in over 500 samples of flora, fauna and soil collected around the Stauffer Chemical Company's operation at Ramsey demonstrate the effects of fluorides that are not removed by their Venturi scrubbers. Fluoride analysis of 1971 and 1972 forage collected in the area demonstrate that forage on 11,520 acres (not including Stauffer Chemical Company properties) contained from 35 to 55 ppm of fluoride (dry wt. basis). Furthermore the forage on 4,736 acres had accumulated 55 to 100 ppm of fluoride; and forage samples on 450 acres (again outside of Stauffers property) had accumulated from 100 to 500 ppm of fluoride. Maps demonstrating fluoride levels in the Stauffer plant area are presented in the appendix of this statement.

Probably the most important data collected around the Stauffer Chemical plant which have the 97% efficient Venturi scrubbers is that the fluoride levels in forage collected from all 11 study radii (which covers 80 to 100 square miles) around the plant site were above the normal fluoride background level for forage of 7 to 10 ppm. Even more revealing is the

Therefore we cannot accept your conclusion that no fluoride damage will occur because your diffusion model demonstrates to you that the State ambient air fluoride standard will not be exceeded.

Exhibit 4

SO_2

Adequate comment on this section is impossible since neither the refined diffusion model nor the new meteorological data are presented. Since the Draft Supplement has revised the maximum SO_2 concentration downward by a factor of 3 the importance of the model and meteorological data are obvious.

The DS states that those conditions necessary for the one hour state standard to be violated are "highly unlikely". There is no data to justify this statement in the DS. We submit that the dismissal of the possibility of the occurrence of conditions favorable for violations of State Air Standards as merely "highly unlikely" without further substantiation is a shirking of responsibility on the part of the Department of Health and Environmental Sciences. This is all the more obvious since the DS admits that the revised predicted SO_2 concentration could be $\frac{1}{2}$ or twice actual levels, and that from the State's experiences violations of state standards do occur.

The SO_2 section is further inadequate and difficient since there is a lack of substantiation for predicting F^-, NO_x and particulate concentrations based upon their relative concentration ratios to SO_2.

Effects on Ecosystems

This section, we submit is again deficient and inadequate. Flourides at concentrations of less than 35 ppm in forage will cause damage to cattle. The Intalco Aluminum Company in Ferndale, Washington recently paid $150,000 in damages to a farmer whose cattle were damaged by consuming

Exhibit 4

vegetation contaminated with F^-. The average flouride concentration in the forage was 26 ppm. The DS expects that "dangerous concentrations" of F^- are not expected to occur in vegetation based upon predicted ambient air fluoride levels, but does not substantiate this expectation with data. Nor does it define "dangerous concentrations." Mention of long term concentration of flouride is made in reference to Ponderosa Pine 17 miles from Colstrip, but range grasses in the immediate vicinity of the plant site with 3 year life cycles, are not considered at all. We submit that the DS does not consider the effects of F^- on the ecosystem since wild indigenous animals are not mentioned at all.

Although the DS indicates that no damage to alfalfa by SO_2 should occur, it is difficient in that it does not enumerate those studies upon which this indication is based. Literature on the effects of SO_2 on vegetation is voluminous and research is continuous. No adequate comment is possible without the bases for the DS's indications of no SO_2 damage to Alfalfa.

The DS is less certain about the synergistic effects of SO_2 and other pollutants. It states that data on synergism is scarce, and that there is no indication from the paucity of data that synergistic process would occur which would damage vegetation. Prudence would seem to dictate that a lack of information and a paucity of data would not be the basis upon which to predict an event.

The section on Effects on Ecosystem is further inadequate in that there is no data supporting the expectation that the physical separation of the cooling towers and the stacks would prevent generation of significant

amounts of H_2SO_4. Although the climate in Colstrip is now dry, the DS ignores any increased humidity as a result of the operation of the cooling towers themselves. Clearly, a substantive statement on sulfuric acid mist is possible only by considering increased humidity. The section is further deficient in that the environmental impact of the amount of acid expected to be formed, although "insignificant" is not considered, nor is a "significant generation of acid mist"defined.

Human Health

The subsection entitled human health is grossly inadequate. One need only refer to the record of the December 15th, 1971 hearing on the Anaconda sulfur dioxide SO_2 petition to note the voluminous literature available on the health effects of air pollution. Such a vital subject as the effects of air pollution on human health deserves more than 5 sentences.

We simply have not had time to comment on the sections entitled, Water Use, Dry Cooling Towers, Powerlines, or Power Use.

Conclusions

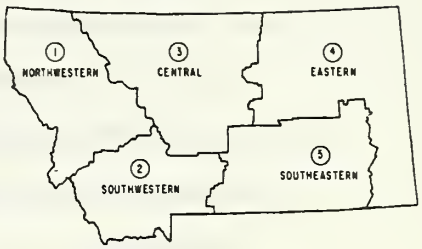
In conclusion we wish to reiterate our objection to the distribution of supplemental materials one day prior to a public hearing which will consider the materials. We believe that the supplemental draft in no way elimates the deficiencies noted in the Draft Statement and in fact is subject to the same shortcomings noted in the draft statement. We therefore urge that the department prepare a revised draft environmental impact statement, as recommended by the Environmental Quality Council, Environmental Defense Fund and Student Environmental Research Center addressing itself to the full impact of this development.

Exhibit 4

EDUCATION -- CONSERVATION

Montana Wildlife Federation

AFFILIATE OF NATIONAL WILDLIFE FEDERATION



STATEMENT PREPARED FOR THE JANUARY 5th PUBLIC HEARING CONCERNING MONTANA POWERS'S APPLICATION FOR CONSTRUCTION OF A COAL FIRED GENERATING PLANT AT COLSTRIP.

My name is Robert Lynam and I reside at 501 Palmer, Miles City, Montana. I am president of the Montana Wildlife Federation and this statement reflects the general policy of that organization.

I have read the draft copy of the Environmental Impact Statement as well as the North Central Power Study and these documents form the basis of my remarks.

The Federations policies reflect concern with the entire environment and while I am concerned with the total environmental consequences of the proposed action, time forces me to narrow my comments to a few. Omission of comment does not imply consent or agreement with the overall plan for the plant or for the energy generation complex in southeastern Montana.

There are two general topics that I will discuss in detail and they are: Air emmissions and water demands.

AIR EMISSIONS:

The impact statement raises the question about the Jim Bridger plant in Wyoming. What will be the effect of emmissions even if the plant complies? Nowhere in the statement do I find this question answered, either about the Bridger plant or the plant at Colstrip. However, the writers summarize in

Exhibit 4

in Item 4 that air quality degradation is a probable adverse effect.

I question also what guarantees that the emission equipment will function as designed? Will the Air Quality Bureau have the ability to stop or scale down operations if the equipment fails? Past experience has taught us that once the investment has been made the regulatory agencies become ineffectual.

The Air Quality Bureau admits in the statement that they expect violations of the 0.25 ppm 1 hour standard for sulphur dioxide. It is difficult to have confidence in these statements when the report states the results are preliminary since input meteorlogical parameters were not founded facts.

TRACE ELEMENTS

The statement contains this quote related to trace elements. "When millions of tons of coal are burned the trace elements become significant potential pollutants." The writers of the statement conclude and I quote, "Very little is known about the trace element content of the coal to be burned at Colstrip. Thorough comprehensive sampling for trace elements has not been done on this coal.

It is important to know how much of these elements will be emitted but it is vital to know the impact of these trace elements upon animals living a normal but stressful life in their natural environment. Will the hunters find eating birds and animals of the area hazardous because of high Mercury levels? The content of mercury and the removal of mercury are admittedly unknowns.

What are the expected deposition levels of fluoride upon the vegetation and ultimately the levels in the animals of the area? What is the fluoride content of the coal and how much will be removed?

Exhibit 4

WATER VAPOR:

The statement contains an estimate of 4 million pounds of water vapor released per hour from the cooling towers and the stacks.

Winter is a very critical time for animals. Will the snowfall increase? Normally available foods and feeding areas may become unavailable to these wintering animals.

WATER DEMANDS.

The water needs for the plant at Colstrip are estimated at 13,000 acre feet per year. Withdrawals in this amount are not expected to have a significant effect on the present flows of the Yellowstone River. However, the Bonneville Power Administration refers to at least two more plants in the Colstrip area in the near future. Other energy companies are planning additional generating plants as well as gasification plants for southeastern Montana.

It is these total water needs which are of great concern to the Federation.

Stabilized flows in the Yellowstone drainage will have adverse effects on the aquatic communities. Paddlefish studies indicate that spawning is triggered by the spring increases in flows. Sauger and walleye depend on clean gravel bars for successful spawning. It is the increase in flows which cleanse the gravel bars of the accumulation of silts.

The water demands can be reduced by incorporating dry cooling towers instead of the evaporative towers. The Federation recommends dry cooling despite the added costs.

The Federation is deeply concerned with the inefficiency of conversion of coal to electrical energy and the high transmission losses. Better methods must be found to convert the non-renewable coal to electrical energy.

The Bonneville Power Administration has requested permission from the Forest Service to run the Colstrip generated power vial high voltage

Exhibit 4

transmission lines through the Magruder Corridor. The Federation opposes this action through this candidate wilderness area.

In summary I find it very difficult and frustrating to make factual comments about the probable impacts of the Montana Power generating plant at Colstrip when the draft statement contains statements such as, efficiency unknown, meteorlogical parameters were not founded facts, no background information, etc. The Montana Wildlife Federation does not oppose the mining of eastern Montana coal, with proper safeguards, but we oppose the granting of this permit until the impacts are more accurately judged and degradation will not occur.

Exhibit 4

STATEMENT OF UNITED STATES FOREST SERVICE

Regarding the Draft

ENVIRONMENTAL IMPACT STATEMENT

For

COLSTRIP POWER PLANT

My name is Dan MacIntyre. I am Forest Supervisor of the Custer National Forest, whose headquarters are at Billings, Montana. I am here to make a statement on the behalf of the Regional Forester of the Northern Region of the Forest Service, Steve Yurich, whose headquarters are at Missoula, Montana.

We have previously submitted a written response to the draft Environmental Impact Statement (EIS) to the State Air Quality Bureau and won't go into the details of that document here today. We would, however, like to summarize our views for the hearing record.

The greatest concern which specialists, line, and staff officers of the Forest Service in the Northern Region have expressed, lies not with the Colstrip Power Plant per se, but with the larger areas and issues which will surely follow and hence are associated with the installation of these first two plants. We suggest, therefore, that we cannot put the plant itself in the proper perspective for meaningful comment except as it relates to the total context of these larger areas and issues.

Exhibit 4

Our first and primary concern, therefore, is for the critical need for a more comprehensive study to assure orderly development and the production of needed power from the entire Fort Union Formation Area, in a manner which will prevent, or at least minimize degradation to the environment, traditional uses, and human resources of the area affected.

We believe that an approval for construction and operation of the first two relatively small facilities discussed in the Environmental Impact Statement would act as a precedent for additional plants in the area. An analysis of the cumulative effects of the ultimate amount of mining and the number, size, and location of plants is needed before piecemeal development is undertaken.

Our second area of concern is for the transmission network issuing from the power plant or plants. We are informed that 350 MW of the 700 MW to be produced from the first two proposed plants at Colstrip would be wheeled to the West Coast. This same informational material shows that an additional 1,050 MW would go west from the second two plants being planned by Montana Power and Puget Sound Power and Light. Thus far, we have been unable to determine where the balance of available power will be directed. We are most anxious to find this out since it is not only possible but quite probable that transmission lines will be planned which would have to cross National Forest lands west of Colstrip.

Exhibit 4

Some prominent transmission line corridor possibilities, in light of the above discussion, are:

1. Colstrip, Montana, west to Anaconda, Montana, westerly across the Saphire Range and Bitterroot Mountains via the Magruder Corridor to south of Lewistown, Idaho, then westerly to the load centers.

2. From Anaconda, Montana, to Hot Springs, Montana, to Spokane, Washington, and south and west to load centers.

3. From Anaconda, Montana, to Hot Springs, Montana, following the present Dworshak Hot Springs Transmission Line to west of Dworshak Dam near Ahsahka, Idaho, via the lower Snake River area to the load centers.

The above possible transmission line corridors could involve directly and indirectly National Forest system lands located on eight National Forests.

There is no evaluation as to the possible transmission line corridors, transmission line capacities, and the environmental impacts involved in moving the needed electricity to the Pacific Northwest load centers.

The report of the Senate Committee on Interior and Insular Affairs, concerning problems of Electrical Power Production in the Southwest (released in the fall of 1972) points out in the Findings section on page 29:

Exhibit 4

"Although the current controversy over the power development in the Southwest has not greatly highlighted transmission lines, it is probable that the ultimate transmission grid contemplated will pose the most severe problems of aesthetic insults to the region."

In considering potential transmission line corridors where National Forest system lands are involved, there are land and resource management considerations involved which must be solved and alternatives considered before final decisions and authorizations can be made. Comprehensive land and resource evaluations and analysis must be completed to ascertain that the proposed transmission line corridor(s) is consistent with other planned activities and would not create serious adverse consequences for long term management. Determination must be made that the portion of a proposed corridor located on intermingled or adjacent land would not adversely and seriously offset important National Forest system values or preclude the achieving of National Forest objectives. Determination must also be made that the proposed corridor location on National Forest system lands would not adversely or seriously affect the environmental quality of intermingled or adjacent land of other ownerships.

Other factors which must be considered are primitive area studies, social and economic impacts, pending legislative action, environmental statements required by the National Environmental Policy Act, public involvement, coordination between all utilities including public,

private, and Federal agencies involved in the production transmission and marketing of electricity. Until the above is accomplished and all alternatives considered, we consider that options related to the allocation of National Forest lands from a diminishing land base must be kept open. Determination of locations and authorization for transmission line cordidor(s) on National Forest land such as discussed above, would require in-depth analysis and Environmental Analysis and Statements.

Our third area of concern relates to stack emissions from the proposed plants. National Forest lands nearest to the proposed Colstrip plant lie approximately 20 to 25 miles to the east. Due to westerly prevailing winds, the projection for uncontrolled emissions of 3.2 pounds per hour of fluroides and 0.23 pounds per hour of mercury are particularly worrisome. These are cumulative poisons and affect plants and animals at relatively low concentrations. Livestock, for instance, develop fluorosis if grazing is done on vegetation containing more than 35 ppm fluoride.

To summarize then, we have three chief concerns:

1. The need for a more comprehensive study for the total impacts of coal development in the entire Fort Union Coal Formation Area.

2. The need for more information and evaluation of the impacts of the transmission network following power plant development.

Exhibit 4

3. The cumulative effects of stack emissions on National Forest lands lying east of the proposed Colstrip plant.

We would urge that the above factors be more fully considered and evaluated before further land use commitments are made.

Exhibit 4

ORAL TESTIMONY OF MR. JAMES M. BENSON AS TRANSCRIBED FROM TAPE MACHINE

I don't suppose I'm any different than any of the rest of us that are here. I probably have a personal reason for coming up and stating my views and mainly I don't see any objections to this issuance of this permit to Montana Power because we surely will need the power in days to come because I know my wife would be awful unhappy if I told her she couldn't use the vacuum or had to do without a refrigerator, but I have followed the construction work most of my life, I've farmed and ranched before that and this project out here affords a lot of us working people the opportunity for year round employment and this I think is what most of us seek as some source of financial security. We as a family discussed and tried to come to a reasonable conclusion as to why we should or shouldn't move to Colstrip and have the chance for year around employment. We like outdoor activities and we hate to see the air, the water, the earth quality of it impaired in any way, and I don't think this steam plant will do this, so I represent myself, mostly, and I the concensus of opinion that I arrived at from talking to the working man at the mine and around Colstrip who work in the mining operation and on the plant seems to be that they find no objection either. As far as strip mining goes I don't think there is many people in Montana that would like to mine that coal underground. I know I wouldn't and I suppose then we would have to import miners from back East to come out here and mine the coal underground, so I don't think we would be doing the young people of Montana any favor by trying to mine it in this manner, so I think that possibly that this is the most economical and most feasible way to mine the coal and to insure us that we have an adequate supply of electricity in the future. Thank you.

Exhibit 4

Exhibit 4

else. They are just designed for normal stream flow. I happened to be president of the Kinsey Irrigation Association in 1961, and we had Cats right down in the bottom of the river trying to get water enough for our farmers to irrigate. Now if Montana Power, whoever it is, would like, we know 90% of the time there is plenty of water running down this Yellowstone River, but what about that 10% of the time. Now are they willing to come in and construct devices for our irrigation projects to get that water out when it is below normal stream flow? Now this is one question I would like to know. There is quite a little water going down there, but we have to have it. Now if they are willing to come along and construct these devices to get the water out, fine, then I would like to go on record from the Tongue River Yellowstone Beet Association as we are not strictly against the two plants or anything else, but we want to know whether we are going to have water to maintain our crops. Now, for instance a dry land farmer probably averages $30 - $40 - $50 an acre off his crops, an irrigated farmer averages, talking gross, from $100 - $500 an acre off of his crops. My budget would look pretty dim, I'd tell you, if I had 175 acres and I got $35 an acre off of it.

That's all I have to say.

Thank you.

Exhibit 4

Exhibit 4

January 5, 1972

I am Mrs. Leon Hicks. I represent the Billings Chapter of the National Audubon Society with membership of 70 families.

We want to thank the State Board of Health for this opportunity to voice some of our concerns about the plant now under construction and of the plants planned for this area in the future.

Audubon does recognize that a valuable resource is present in great quantities and that there exists a demand for it. Audubon questions the haste with which industry is moving before adequate safeguards over soil, air and water can be established.

As we understand the situation, the only permit needed for operation of this plant is the one concerning the installation of air pollution control equipement. The entire plant abuses several areas of the environment and the delay in filing the impact statement by Montana Power Company violates the intent of the NEPA act and the right of the citizen to know about proposed development in our state.

Montana Power has filed a request at the Rosebud County Courthouse for rights to 59 billion gallons of water a year. They have filed for approximately 112,000 gallons a minute while insisting to the public that they will be using only 8000 gallons a minute in the operation of this plant. Why did they file for such an excessive amount?

Who is the authority for the statement that removing this amount of water from the Yellowstone would not harm the river or the plant and animal life dependent upon its water? Considering other demands already made upstream upon the river, is there any basis for such confidence in the rivers ability to withstand this heavy demand upon it.

Audubon urges that dry cooling towers be used. There is a shortage of fresh water in the United States and it just is not reasonable to use this resource in such an extravagant fashion.

Montana Power claims that they are bringing jobs to Montana so that our youth does not have to go elsewhere for employment. The impact statement says 800 to 900 jobs will be available during the building of this plant, but less than 100 will be needed to operate it and the strip mining operation later. Where will the extra 800 men work after the plant is finished in 1976? Who will use their former housing?

We must presume that city services and schools will be expanded to accomodate the extra people for four years. Is this really a sensible 5 year plan for Montana?

Consider the economic catastrophe when the government pulled out of Glasgow and Conrad. Is it desireable to replace a stable agricultural economy with a boom and bust construction economy? Audubon questions the validity of Montana Power's assertion that they are improving the economy here for anything but a very short period of time. The unemployment problem will be MONTANAS!

The Department of the Interior has conducted a study of the Four Corners steam generation area in the southwestern United States and has drawn the conclusion that it is much cheaper to ship the coal to the population centers for conversion into energy than it is to build mine mouth plants and then ship the energy. In Eastern Montana, the major rail lines already exist for the shipping of the coal to the eastern or western population centers.

This one plant projects three separate power lines to Billings. Since 20 acres of land is condemned for every mile of power line built, this visual and land consuming pollution could be avoided if the coal were shipped to population centers instead of building future

Exhibit 4

mine mouth plants.

Why degrade Montana's air and water and land when it is cheaper to ship the coal to the consumer's area?

What assurance do we have that existing pollution controls will be honored by the Power companies and if not honored, what assurance do we have that violations will be corrected and the law enforced? Past performance of the Power Companies does not engender confidence

Granting a permit to operate means that coal must be mined and with strip mining now permitted under existing laws, it will be strip mined since this is the cheapest and fastest way to utilize the resource. Would it make more sense to deep mine the coal and thereby exercise the subsurface rights while preserving surface rights and maintaining the environment? This method of mining would create many more permanent jobs than strip mining will.

If there really is such an energy shortage and they really do need this coal now, wouldn't they be happy to pay the extra price of deep mining so as not to cause the disruption of people and wildlife and plantlife?

Audubon recognizes other values besides a dollar and how many acres it takes to graze a cow. Several other values can be placed on any given piece of real estate. How long will it take to grow the trees again? The grass? Or rebuild the soil?

If there is any other way to get the coal, why should strip mining even be considered when it is common knowledge that other strip mined areas are useless for generations.

Which is really more important? Preserving the land for the next generations or destroying it during this one to satisfy an artificial urgency for more energy in order to manufacture throw away containers, gadgets that comb your hair, brush your teeth, and open your cans. Energy to produce cars with many times the horsepower needed to get from here to there, light our streets like midday at midnight, illuminate billboards, keep the neon flashing bigger and brighter far into the night.

Audubon is concerned the power companies don't really want us to know the truth about the energy situation. Why do they continue to advertise to increase demands for a product they say is already in short supply?

Audubon is concerned that the state might really believe that 500 foot smokestacks or even taller ones somehow lessen the pollution pouring from them. We have only this one world.. Does it really make a difference how high they shoot the pollutants as long as they remain in our world? From this one plant 266 pounds of dust an hour, 6820 pounds of sulphur dioxide an hour, a maximum of 4774 pounds an hour of nitrogen oxides, with a yearly maximum of 14 tons of water vapor all add to the pollution we already have... Let us not be perpetrate's of another "Legal crime" against the State of Montana.

[redacted]

Exhibit 4

Presented To The State Board
Of Health Concerning The Proposed Steam Generation Plant
At Colstrip.

Miles City, Montana January 5, 1973

By Don Bailey
Forsyth, Montana

I am Don Bailey. My livilihood is sustained from a family ranching operation approximately 10 miles southwest of Colstrip. The threat that accumulative pollution effects may impose upon my future welfare, both physically and economically, have prompted my remarks.

Because others have or will deal in specifics of the impact statement, I have chosen to comment more in generalities.

The statement concludes, in many instances, that there probably is not enough information available to properly determine the long-range effects that the power plant may have on the environment and eco-systems.

The only criteria that must be met are the State and Federal ambient air quality standards. That these standards are considered adequate, is only confirmed in the impact statement, by the Administrator of the Environmental Protection Agency in establishing these standards. The national secondary ambient air quality standards are those which, in the judgment of the administrator, based on air quality criteria, are requisite to protect the public welfare from any known or anticipated adverse effects associated with air pollutants in the ambient air.

Exhibit 4

Admissions are made throughout the impact statement that long range adverse effects will undoubtedly be imposed upon the environment. This appears to me to be an anticipated event, and by definition of the Ambient Air Quality Standards, would mean that it cannot meet these standards. There will be pollution, there will be adverse effects, and they are being anticipated now.

The State Board of Health wrote this impact statement on the basis of information supplied them by the Montana Power Co. Much of the back-ground research was done by firms or agencies that were partially or wholly funded by the Montana Power Co. or other utility oriented industries.

This situation raises the question as to whether every bit of information, both negative and positive to their plans, has in fact, been made available to the State Board of Health.

We in America, have continuously introduced substances into our environment, with good intentions, that were judged to be completely safe. Later, as in the case of DES in livestock feeding, many food additives, and medicinal drugs, it was discovered that they created a definite health hagard. No tolerance was allowed as will be the case of the florides, which have definitely been linked with heart disease and bone deterioration, or the radioactive ones which can cause cancer; these being only two of many dangerous elements resulting from the burning of coal. The reasoning for the variations in this interpretation smells of political overtones.

I fear that one day we will discover our tolerance of these deadly substances, only for the economic benefit of our industries, was also a grave error in human judgment. Is the health and welfare of the people of Montana and the Colstrip area in particular, to pay for this kind of irresponsible actions?

Exhibit 4

I might add that I realize the economic importance that coal mining and its related activities have to the men and their families who work at Colstrip, but because they are on the other end of the philosophical ladder on this matter does not make them immune from the pollutants of this project. The wind does not always blow from the west at Colstrip.

I will briefly list some other problems, as revealed to me by air quality experts with whom I have been in contact, that may result from the 700 Meg. Watt plant.

1. Ponderosa pine within a five mile radius downwind may be severely damaged or completely destroyed by fluoride emissions. The impact statement says that no control equipment or ambient air quality standards will be in effect for fluorids.
2. Acid rains resulting from present annual rain fall and large amounts of evaporated water from the plant, combining with sulphur dioxide emissions, may reduce plant growth in the surrounding eco-system by 1/3 within five years. This is recognizing the advertised 99.5% efficiency in removing particulate and SO_2.
3. Dr. Earnest F Abicht, a research scientist for the Environmental Defense Fund says the loss of 1% efficiency of the control equipment will increase the SO_2 emissions four times. This, of course, can be taken care of by the 24 hour grace period allowed every four days, whereby, any amount of pollutants into the ambient air will be allowed for 24 hours.
4. These same air quality experts have indicated the most dangerous of all effluients may be the trace elements.

Exhibit 4

I quote from the impact statement, "Very little is known about the trace element contents of the coal to be burned at Colstrip. Thorough comprehensive sampling for trace elements has not been done on this coal. Mercury and fluorine have been the trace elements given the most attention, but others may prove to be serious pollutants, especially radio-active ones." (unquote)

I have pointed out only a few of many inconsistancies in the impact statement. There have been and will be some other circumstances evolve from this action which I feel deserve consideration.

1. We will have the creation of a pottntially dangereous pollutant with inadequate regulations to assure that even the tolerable or acceptable degree of pollution will be maintained.
2. We will have a long term accumulation of toxicants in flora and fauna . The effects of this accumulation may not be readily recognized until serious damage has been sustained.
3. There is apparently no legal rexourse for those in the area who may be damaged physically or economically.
4. We have had an apparent after-the-fact atmosphere which has shrouded this project from its inception. By after-the-fact, I refer to the publishing of the impact statement, the construction application, the determination of when the permit is required and finally the ultimate issuance of the permit. I detect a very dangereous precident being se if this is a format for future projects.
5. We have an irreversible commitment of four precious natural resources, land, air, coal, and water at a 12% efficiency. It does not seem that this is commendable

with the needs of a nation that is supposedly on a brink of a major energy and natural resource crisis.

In conclusion, in view of my testimony, I believe it would be very commendable, courageous, and politically inexpediant if the Board of Health were to refuse the permit application at the time when it is determined necessary for construction to begin or continue, until such time as a more educated and responsible decision can be made.

Exhibit 4

Exhibit 4

Mr. Race

WHILE REALIZING THAT A STATEMENT AT A HEARING OF THIS KIND SHOULD BE CONSTRUCTIVE, AND THAT MY COMMENTS WILL PROBABLY BE DISREGARDED BECAUSE THEY ARE NOT DIRECTLY RELATED TO THE CONTENT OF THE DRAFT ENVIRONMENTAL IMPACT STATEMENT, I FEEL THAT IT IS MORE IMPORTANT TO TAKE A BROADER VIEW OF THE IMPLICATIONS OF THE COLSTRIP PLANTS, THAN TO MERELY COMMENT ON WHAT I CONSIDER ARE GROSS INADEQUACIES IN THE IMPACT STATEMENT.

I CONSIDER THIS HEARING, AND ALL OF THE EVENTS LEADING UP TO IT, TO BE A WASTE OF TIME, EFFORT, AND MONEY. I BELIEVE THAT THE SO-CALLED CONSTRUCTION PERMIT HAS BECOME A FRAUD AND A FACADE, AND WHILE THE MONTANA POWER CO. IS PROBABLY WITHIN THE LEGAL LIMITS OF THE LAW, THEY HAVE VIOLATED THE INTENT, AND PURPOSE OF THE LAW, AND HAVE MADE A MOCKERY AND A LAUGHING-STOCK OF THE BOARD OF HEALTH, THAT ADMINISTERS THE LAW, THE LEGISLATURE THAT ENACTED THE LAW, AND THE STATE, AND ITS PEOPLE THAT THE LAW WAS DESIGNED TO PROTECT.

THERE APPEARS TO BE UNINIMITY BETWEEN MONTANA POWER CO.'S HIERARCHY, AND ME ON ONE POINT, AND THAT IS THAT THE PENDING APPLICATION FOR PERMIT WILL BE SUMMARILY APPROVED, AND THAT APPROVAL FOR OTHER PLANTS AT COLSTRIP WILL BE ROUTINELY APPROVED, AS WELL.

THE PROPOSED CONSTRUCTION OF A FIVE-FOOT PIPELINE FOR WATER, WHEN ONLY A TWO-FOOT LINE IS REQUIRED TO COOL THE TWO PLANTS UNDER CONSTRUCTION; COUPLED WITH THE ADMISSION OF A WESTERN ENERGY CO. OFFICIAL TO A GROUP OF PEOPLE AT COLSTRIP THAT SEVEN PLANTS, WITH A TOTAL GENERATION CAPACITY OF 10,000 MEGA-WATTS, WILL EVENTUALLY BE BUILT AT COLSTRIP IS HARDLY A COINCIDENCE.

IS THE ONGOING CONSTRUCTION OF THE POWER PLANTS, THE SURVEYING OF THE PIPELINE ROUTE, THE CONSTRUCTION OF ADDITIONAL TRAILER COURTS AT COLSTRIP, THE CONSTRUCTION OF TRANSMISSION LINES, CONSISTENT WITH ANY DOUBTS AS TO THE FINAL DISPOSITION OF THE APPLICATION FOR CONSTRUCTION? I THINK NOT, AND ONCE AGAIN I BELIEVE THAT MONTANA POWER AGREES WITH ME.

I QUOTE FROM THE IMPACT STATEMENT, UNDER EFFECTS ON THE ECOSYSTEM ON PAGE 22: "WHAT THE LONG RANGE EFFECTS OF SO_2, NO_X, FLORIDES, MERCURY AND

Exhibit 4

OTHER EMISSIONS FROM THE PROPOSED PLANT WILL BE, IS IMPOSSIBLE TO PREDICT AT THIS TIME.....OVER A PERIOD OF YEARS, THE POLLUTANTS MAY BUILD UP TO LEVELS THAT SERIOUSLY DISRUPT THE ECOSYSTEM.....A QUANITATIVE ESTIMATE OF THESE EFFECTS IS IMPOSSIBLE AT THIS POINT IN TIME, GIVEN OUR PRESENT UNDERSTANDING OF THE FATE OF THE POLLUTANTS IN THE ECOSYSTEM." DR. ERNST HABICHT, JR., OF THE ENVIRONMENTAL DEFENSE FUND MADE THE FOLLOWING COMMENT ON THIS PART OF THE IMPACT STATEMENT: "INSTEAD OF DELVING INTO THIS SUBJECT, THE DRAFT ENVIRONMENTAL IMPACT STATEMENT APPEARS TO SUCCUMB TO HELPLESSNESS, AS IF THE FATE OF THE REGION WERE COMPLETELY IN THE HANDS OF THE MONTANA POWER CO."

PRELIMINARY AIR SAMPLING WAS DONE PRIMARILY ALONG DUSTY COUNTY ROADS, AND THE MAIN, RURAL SAMPLING SITE, MENTIONED ON PAGE 13 OF THE IMPACT STATEMENT, WAS IN ONE OF MY NEIGHBOR'S YARDS, DOWNWIND FROM ALL OF THE DAILY TRAFFIC THROUGH THE YARD, AND IN CLOSE PROXIMITY TO A TRASH-BURNING BARREL. I MENTION THIS MORE AS A PROTEST TO THE ACCURACY OF THE STATEMENT, RATHER THAN THE EFFECT IT MIGHT HAVE ON THE APPLICATION'S FINAL DISPOSITION. I GUESS WHAT I AM TRYING TO SAY IS, THAT IN THE VERY LIMITED AREA OF MY PERSONAL EXPERTISE, THE INPUT INTO THE IMPACT STATEMENT IN THE CRITICAL AREA OF PRESENT AIR QUALITY IS ERRONEOUS.

THE ONLY CONSOLATION THAT I CAN FIND IN THE IMPACT STATEMENT IS FOUND IN THE SUMMARY WHICH SAYS: " THE LONG-TERM ADVERSE EFFECTS MAY WELL OUTWEIGH THE SHORT-TERM GAINS."

WHAT I FEAR IS THE PROSPECT THAT BY APPROVING THIS FIRST FACILITY A PRECEDENT WILL BE SET FOR SUBSEQUENT FACILITIES, AND THAT THE BIG SKY COUNTRY WILL ENVIRONMENTALLY SUBSIDIZE THROUGH INEFFICIENT GENERATION, AND INEFFICIENT TRANSMISSION, NON-MONTANA ELECTRICITY CONSUMERS, AND NON-MONTANA FINANCIAL INVESTORS.

A FRENCH PHILOSOPHER NAMED RAYNAL ONCE SAID: "THERE IS AN INFINITY OF POLITICAL ERRORS WHICH, BEING ONCE ADOPTED, BECOME PRINCIPLES." I HOPE AGAINST HOPE, AND PRAY AGAINST MY INTUITION, ADMITTING THAT I AM BIASED, THAT

Exhibit 4

AND CYNICAL, THAT YOU WILL REFUSE THE APPLICATION FOR CONSTRUCTION.

Exhibit 4

Exhibit 4

A STATEMENT BEFORE THE DEPARTMENT OF HEALTH & ENVIRONMENTAL SCIENCES COMMITTEE IN PUBLIC HEARING ON THE MATTER OF MONTANA POWER'S APPLICATION FOR A PERMIT TO CONSTRUCT GENERATION FACILITIES AT COLSTRIP

MY NAME IS PETER LOMBARDOZZI, I AM THE PRESIDENT OF THE SOUTHEASTERN MONTANA BUILDING TRADES COUNCIL, AND I AM ALSO THE BUSINESS MANAGER OF THE INTERNATIONAL BORTHERHOOD OF ELECTRICAL WORKERS, LOCAL 532, AND THE FOLLOWING STATEMENT IS PRESENTED ON BEHALF OF BOTH ORGANIZATIONS.

THE SOUTHEASTERN MONTANA BUILDING TRADES COUNCIL IS AN AFFILIATION OF THIRTEEN CONSTRUCTION UNIONS HAVING A COMBINED MEMBERSHIP OF WELL OVER 3,000 MEMBERS. ONE OF OUR FUNDAMENTAL CONCERNS AS A LABOR UNION ORGANIZATION IS A CONTINUING SUPPLY OF WORK FOR WAGE EARNERS AND OF COURSE, THIS IS OUR FIRST INTEREST IN THE DEVELOPMENT OF THE MONTANA POWER COLSTRIP STEAM PLANT PROJECT.

THE DEVELOPMENT OF MONTANA POWER ELECTRICAL ENERGY COMPLEX WILL PROVIDE A NEED FOR A WIDE VARIETY OF PHYSICAL AND TECHNOLOGICAL SKILLS, NOT ONLY FROM THE INITIAL CONSTRUCTION OF THE FACILITIES, BUT FROM THE OPERATION AND PRODUCTION OF THE PLANTS. WE ARE CONVINCED THAT MONTANANS WILL BENEFIT FROM THE JOB IMPACT ON THE ECONOMY FROM NOW ON.

THE RESULTING JOBS EFFECT NOT ONLY THE MEN AND WOMEN DIRECTLY EMPLOYED BUT EVERY MEMBER OF THEIR FAMILIES. WHEN PEOPLE ARE ABLE TO WORK, THEY SPEND THEIR MONEY ON GOODS AND SERVICES PROVIDED BY BUSINESSES WHO IN TURN HAVE TO HIRE MORE PEOPLE TO PROVIDE THE ADDED SERVICES, AND IT GOES ON AND ON.

PEOPLE WHO ARE ABLE TO WORK, ARE ABLE TO PAY TAXES. MOREOVER, THE GENERATING FACILITIES THEMSELVES WOULD PROVIDE AN ADVANTAGEOUS TAX BASE. THE PEOPLE IN MONTANA SHOULD BENEFIT FROM THE ADDITION OF THIS TAX BASE TO THEIR OTHER TAX ROLLS.

Exhibit 4

IN ANOTHER SENSE, THE JOBS PROVIDED WILL AFFORD MORE OF OUR YOUNG PEOPLE WHO HAVE COMPLETED THEIR EDUCATION AND ARE LOOKING FOR A CAREER AND A WAY TO REMAIN IN THE STATE A CHANCE TO STAY IN MONTANA AND GROW WITH MONTANA.

WE BELIEVE THAT MONTANA'S NATURAL RESOURCES HAVE TO BE DEVELOPED IF MONTANA IS TO GROW AND PROSPER, AND THE WELL BEING OF ITS PEOPLE DEPENDS HEAVILY ON THIS GROWTH.

ROLLING PLAINS OF SAGE-BRUSH AND GRASS ARE PLEASING TO THE EYE BUT UNFORTUNATELY FOR A MAJORITY OF THE PEOPLE IN THE STATE, IT CANNOT FEED A FAMILY, SEND A BOY TO COLLEGE, BUY A HOME, OR INSURE SOME KIND OF FINANCIAL STABILITY FOR THEM. DEVELOPMENT OF OUR NATURAL RESOURCES CAN DO THIS.

WE WISH IT PLAINLY UNDERSTOOD THAT WE ARE AS CONCERNED ABOUT OUR ECOLOGICAL ENVIRONMENT AS ANYONE ELSE. WE ARE IN ACCORD WITH THE PREMISE THAT ANY DEVELOPMENT WHICH AFFECTS OUR ECOLOGY SHOULD HAVE STRONG ENVIRONMENTAL CONTROLS TO INSURE THE QUALITY OF OUR WATER, AIR, AND LAND. WE ARE NOT INTERESTED IN CREATING JOBS TO DESTROY OUR ENVIRONMENT!

YET WE TAKE THE POSITION THAT MONTANA CAN DEVELOP ITS NATURAL RESOURCES, PROVIDING WORK OPPORTUNITIES AND GROWTH FOR ITS PEOPLE AND AT THE SAME TIME ENJOY A CLEAN ENVIRONMENT AND ECOLOGICAL BALANCE. WE IN LABOR HAVE SEEN GIANT TECHNOLOGICAL STEPS FORWARD TAKEN BY INDUSTRY AND HAVE PARTICIPATED IN PROJECTS TO REDUCE OR ELIMINATE EXISTING POLLUTION PROBLEMS AND CONTROL FUTURE SOURCES OF SUCH DIFFICULTIES. WE HAVE PARTICIPATED IN THE CONSTRUCTION OF COAL-FIRED STEAM PLANT PROJECTS FROM THE VERY FIRST ONE THAT WAS BUILT. WE HAVE BEEN 'ON THE SPOT WITNESSES' TO THE ASTOUNDING ADVANCES MADE BY THE INDUSTRY IN DEVELOPING TECHNIQUES TO ELIMINATE POLLUTION. WE ARE EXTREMELY CONFIDENT AND OPTOMISTIC THAT AMERICAN KNOW-HOW WILL CONTINUE TO DEVELOP BETTER TECHNOLOGY TO ELIMINATE POLLUTION PROBLEMS.

Exhibit 4

WE HAVE STUDIED MONTANA POWER'S ENVIRONMENTAL CONTROL TECHNIQUES PROPOSED ON THIS PROJECT AND ARE CONVINCED THEY ARE GOING TO UTILIZE THE BEST METHODS AVAILABLE IN POLLUTION CONTROL AT THE PRESENT TIME. WE ALSO BELIEVE THAT WHEN AMERICAN TECHNOLOGY PROVIDES BETTER METHODS AND SYSTEMS OF CONTROL, THEY WILL UTILIZE THOSE METHODS ALSO, BECAUSE NO ONE, BE THEY GOVERNMENT, INDUSTRY, OR WORKERS, WILL ANY LONGER IGNORE POLLUTION PROBLEMS OF OUR LAND, WATER, AND AIR. ENVIRONMENTALISTS HAVE DONE AN EXTREMELY GOOD JOB OF WAKING UP AMERICA TO THE CONSEQUENCES OF PULLUTION.

OUR UNIONS ALSO KNOW THAT AN ELECTRICAL ENERGY CRISIS IS AT HAND, AND THAT THE LOW-SULPHUR CONTENT COAL SUPPLY THAT IS IN GREAT ABUNDANCE IN MONTANA IS THE MOST ECONOMICAL METHOD OF GENERATING ELECTRICAL ENERGY FOR MONTANA AND OTHER STATES IN NEED OF SUCH POWER.

IT WOULD BE DANGEROUSLY NAIVE FOR MONTANANS TO BELIEVE THAT THEY CAN ISOLATE THIS RESOURCE FROM DEVELOPMENT WHEN THE NEED FOR IT IS SO GREAT IN OUR UNITED STATES. SINCE IT HAS TO BE DEVELOPED, WE BELIEVE THAT IT SHOULD BE DEVELOPED <u>BY MONTANANS, IN MONTANA, FOR THE BENEFIT OF ITS PEOPLE</u>! MOREOVER, IT THIS DEVELOPMENT IS TURNED DOWN OR NEEDLESSLY DELAYED, THE FORCE OF '<u>UNMET DEMAND FOR POWER</u>' IN AREAS AROUND US MIGHT CAUSE THIS TO BE UNDERTAKEN BY OTHERS AT A LATER DATE ON A SPEEDED UP OR CRASH BASIS WITHOUT REGARD TO OUR ENVIRONMENTAL QUALITY. WE SIMPLY CANNOT STAND BY, TAKING NO ACTION, OR ALLOWING ANY ACTION BY MONTANA CONCERNS, TO DEVELOP THIS POWER SOURCE. IF WE DO, WE MIGHT WELL LOSE THE INITIATIVE TO OUTSIDE INTERESTS FOR ITS DEVELOPMENT.

Exhibit 4

IN SUMMARY, I WOULD POINT OUT AGAIN:

THAT WE BELIEVE MONTANA POWER'S GENERATION PROJECT AT COLSTRIP WILL CREATE NEEDED JOBS IN MANY CATAGORIES OF WORK NOW AND IN THE FUTURE: JOBS THAT ARE VITAL TO THE CONTINUED HEALTHY GROWTH OF MONTANA'S ECONOMY.

THAT WE BELIEVE THE EXTENDED TAX BASE THIS COMPLEX WOULD BRING CAN ONLY BENEFIT THE TAX PAYERS IN THIS STATE.

THAT WE BELIEVE MONTANA'S NATURAL RESOURCES SHOULD BE DEVELOPED FOR THE GOOD OF MONTANANS WITH ADEQUATE CONTROLS TO PROTECT OUR ENVIRONMENT.

THAT WE BELIEVE A BALANCE MUST BE STRUCK IN THE DEVELOPMENT OF POLLUTION CONTROLS, WHICH WILL FOSTER BOTH ECONOMIC GROWTH AND ENVIRONMENTAL UPGRADING AND THAT WE CAN SUSTAIN INDUSTRIAL DEVELOPMENT AND ENVIRONMENTAL QUALITY TOGETHER BECAUSE OF NEW AND FUTURE TECHNOLOGIES.

IT IS STATISTICAL FACT THAT A POWER SHORTAGE EXISTS IN OUR COUNTRY AND THE MOST FEASIBLE SOLUTION IS TO DEVELOP MONTANA'S ABUNDANCE OF LOW-SULPHUR COAL.

WE ARE CONVINCED MONTANA POWER COMPANY CAN AND WILL MEET TODAY'S REQUIREMENTS FOR ECOLOGICAL BALANCE AND POLLUTION CONTROL AND IN THE FUTURE WILL UPGRADE THESE EFFORTS AS NEW LAWS, STANDARDS, DEVICES AND PRACTICES ARE DEVELOPED.

THEREFORE, THE SOUTHEASTERN MONTANA BUILDING TRADES COUNCIL AND MY OWN LOCAL UNION 532, IBEW, WISHES TO GO ON RECORD AT THIS HEARING OF BEING IN FAVOR OF THE CONSTRUCTION OF THE MONTANA POWER COMPANY COLSTRIP COMPLEX AS BEING IN THE BEST INTERESTS OF THE MAJORITY OF THE PEOPLE IN THIS STATE AND URGE THAT A PERMIT BE GRANTED TO THEM FOR CONSTRUCTION AND INSTALLATION OF THE EQUIPMENT NEEDED FOR THEIR GENERATION FACILITY.

THANK YOU.

Peter Lombardozzi

ITEM
#4

STATEMENT BEFORE THE DEPARTMENT OF HEALTH
AND
ENVIRONMENTAL SCIENCES IN THE STATE OF MONTANA

Miles City, Montana
January 5, 1973

My name is John W. Ellis, Vice President-Utility Management and Chief Operating Officer of Puget Sound Power & Light Company. As you know, Puget Power and Montana Power Company will jointly own and operate the two-unit coal-fired power plant near Colstrip, which is the subject of this hearing.

My purpose today is not to get into the specific environmental issues, but is more general; to explain to you why Puget is involved in this project -- a project far from our home base in the Puget Sound region, two states away. Intimations have been made that "carpet baggers from Washington" are coming into the state to "exploit and run". The concern of the Montana citizens about their environment and this project is certainly understandable, and a brief explanation of our role is in order.

Although our partnership with Montana for the Colstrip project did not come into being until August of this year, the fact is that Puget and Montana Power Company have been "pooling" resources and facilities for many years. Montana Power Company and five other major investor-owned utilities in Idaho, Washington and Oregon first formed the Northwest Power Pool in 1941 in an effort to coordinate their power generation and transmission facilities. In 1942, a War Production Board order directed all utilities throughout the United States to cooperate with each other to assure carrying the maximum loads during the World War II period. Puget, and all the other major

Exhibit 4

systems in the area, both public and investor-owned, joined the pool at that time. Following the war, the utilities decided that the gains to be realized through coordinated operation were so great that the pool should be continued. For many years, until the 1960's, pool operation was strictly voluntary, but very successful; and, I might add, some years ahead of other regional groups in the United States.

In September 1964, a formal Coordination Agreement was signed by all the major electric utilities in the Northwest, including Montana Power and Puget. One of the purposes of the agreement was to firm up coordination of reservoir storage water releases during the drawdown season and in turn provide for sharing the costs of upstream reservoirs. The Agreement also required each participating system to establish a firm energy-load-carrying capability and to maintain that capability through power interchanges with other systems.

Currently, all the utilities in the pool area participate in setting up an annual operating program. This program serves as a basic guide for the coordinated operation of all plants in the pool during the year. With the Coordination Agreement, scheduled utilization of storage water from reservoirs of those systems covered by the Agreement is on a firm basis. There are also other areas of coordination which have been achieved on a voluntary basis in the pool over the years. One of these is setting up a coordinated maintenance schedule each year where outages for maintenance are scheduled based upon load requirements and the available surplus in the pool. Another is in the hourly interchange accounting. These transactions between utilities are handled on a scheduled basis

and all schedules are balanced out against the actual interchanges each hour.

The pool utilities cooperate with each other in the operation of reactive equipment to maintain satisfactory voltage levels throughout the transmission system. The utilities have also agreed on procedures to be followed by the entire pool during cases of emergency. This includes a comprehensive load-dropping schedule for use during emergencies. Frequency relays have been installed and their pick-up times coordinated to provide for dropping a substantial amount of the total load, if necessary. The new transmission ties constructed in recent years between the Northwest Power Pool and other operating areas to the south and east further strengthen the benefits to be derived from pool operations.

It has been said, "No man is an island", meaning that no one should exist isolated in his own community. This is especially true for electric utilities and has been borne out very emphatically by the Northeast blackout and similar occurrences in other parts of the country where systems with less interconnections and less coordinated operations than exist in the Northwest have suffered accordingly. The benefits and gains which are realized through coordination and the various phases of operation in the Northwest Power Pool have resulted in substantially less investment costs due to the need for less transmission and generation facilities; increased load-carrying capability; reduced reserves; significant improvement in reliability; and improvement in the quality of electric service.

It should also be pointed out that reduction in the need for generation and transmission facilities directly translates to less

use of our valuable natural resources, including land and fuels. Also, less environmental impacts need to be imposed upon the region.

You can see, then, that in an indirect but very real way, Puget has been doing business in Montana for many years, to the benefit of Montana as well as to Washington. The reverse is also true.

What I have been discussing so far are benefits related in general to the Northwest Power Pool operations. Within the pool, utilities can gain other benefits through additional arrangements between themselves. Examples include individual interchanges, sales, and wheeling agreements. Such has been the case between Montana Power Company and Puget Power for the past several years. Short-term agreements have been executed between Montana Power Company and Puget Power in the last few years to interchange capacity and energy. Progress is being made on a long-term interchange agreement between our respective companies. This will mean significant benefits to the owners and customers of Montana Power Company as well as to owners and customers of Puget.

For instance, at this time the construction of generation at Colstrip appears to be the most feasible solution to energy shortages occurring in the mid-1970's. However, as we move into the 1980's, more nuclear plants will be coming on the line. Long-range plans for the pool show that a number of these nuclear plants will be constructed in Washington State. Our company is currently planning such a plant for operation in 1982. The benefits of interchanges between our two companies will then be more apparent to the customers of Montana Power Company. Montana Power may well obtain shares of these nuclear

plants to carry its increased loads during that period. The point is that a power interchange is a two-way street.

One other fact of electric life should be noted. Neither Puget, nor Montana, nor any other system could be wholly independent, even if it wished. The Pacific Northwest, the Pacific Southwest, and the Idaho-Wyoming-Montana and Utah area are all tied together by major transmission lines of varying capacities. This transmission network essentially describes an oval running along the Pacific coast, then east to Arizona, north through Montana and Idaho, and returning back to the coast. Each system in this network is affected electrically by whatever happens elsewhere on the system. A failure of the Hanford nuclear plant in Washington State, for example, may well cause -- and as a matter of fact, has caused -- the lights to go out in Arizona. In order for this network to be properly balanced, generation must be located strategically, both with respect to load and current flow. Presently the portion of this circle -- which we refer to as "the doughnut" -- which runs through the eastern segment is an area of abnormal current flows by reason of the dissimilarity between load and generation. Difficulties have been experienced in this area -- and these will become even greater unless action is taken. In order for this network to operate more successfully, generation on the eastern side of this doughnut is very desirable.

An additional benefit to Montana Power Company and its customers in my Company's participation in the Colstrip project is a substantial reduction in unit costs by immediate consideration of two units for construction, rather than one unit. The engineer-

contractor for the project, the Bechtel Corporation, has estimated that the savings in a two-unit project, as compared to the one-unit project already decided upon by Montana Power Company solely for its own immediate needs, amounts to about 17 million dollars, a unit cost of $234 per kilowatt rather than $289 per kilowatt.

Much has been said -- and will be said -- about the project's impact upon the natural environment. I must say that Puget Power shares the concern of you Montana citizens for environmental values. In the past few years, Puget has developed a regional and even national repurtation for being a responsible steward of our natural resources. We have developed numerous company programs relating to undergrounding of distribution lines, development of public recreation areas and trails, aesthetics of lines and facilities, and fish conservation. Ralph Davis, President of Puget Power, was recently named Chairman of the Committee on Environment for the Edison Electric Institute. Our participation in the Colstrip project is absolutely dependent upon its being environmentally sound, as well as economically feasible.

In summary, participation of Puget Power in the Colstrip project does not represent a "cut and run" philosophy, nor is our involvement here something new to the State. Through the Northwest Power Pool and other coordinated activities, through interchange agreements and other arrangements, Puget and Montana have been doing business together for many years with mutual benefit to each company, its customers, and each region. Our company is environmentally responsible. We will insist that all local,

state and federal regulations be met, or bettered by the project. We believe that this project can provide both protection to environmental values and benefit to the economic well-being of your area.

Thank you for the opportunity to appear at this hearing.

ALTERNATIVES IN ENERGY USE

I. Alternatives in Energy Conversion

A. Fossil Fuels and Organic Fuels

1. Petroleum.

Uses: electrical generation, water, space and industrial processes, heat, transportation propulsion, lubrication
Feasibility: presently available; 30-50 year world supply remaining.
Efficiency of use: electrical generation = 35%; house heat = 80%; transportation = varies (car = 12%); 53.2% of petroleum consumption is for transportation.

Environmental Factors:
Production: ecological damages; spillage problems; land use; brine disposal
Shipment: spillage; major spill hazard; consumption of energy with pollution.
Refining: thermal pollution; spent caustic and solid wastes; emissions of SO_2, HC, NO_x and odors.
Utilization: emissions of SO_2, NO_x, CO_2, waste heat if burned; emissions of NO_x, CO, unburned hydrocarbons from internal combustion (which also emits gasoline additives including lead.)

2. Oil Shale

Uses: to petroleum; see I.A.1 above
Feasibility: pilot tests have proven feasibility; could have major production in 5-10 years; economics are present barrier.
Efficiency of use: see oil above.

Environmental Factors:
Production: strip mining; land use; disposal of spent shale 50% greater in volume than original shale; leaching of acids and minerals from spent shale; consumption of water (3 bbl water per bbl oil produced), emissions to air of SO_2, NO_x, HC, particulates. Problem of environmental quality is partially in vastness of land areas which could be disturbed.

Utilization: see oil

3. Natural Gas

Uses: electrical generation; water and space heating; cooking and other domestic and industrial heat uses.
Feasibility: presently available; 10-20 year world supply available.
Efficiency of use: electrical generation 35%; house heat 80%; water, residential and industrial process heat = unknown. 32.6% used for household and commercial, 46.6% used for industrial, 17.8% used for electrical generation.

Exhibit 4

Environmental Factors;
Production: land use; water consumption if liquid.
Transportation: pipeline land use and hazard by vehicle, rail. NO_x emissions at pipeline compressor stations.

Utilization: thermal pollution, CO_2, NO_x, some CO.
Comments: liquid petroleum gas, gases from refining of petroleum, augment supplies of natural gas, have similar uses and effects.

4. Natural Gas by Nuclear Stimulation

Uses: see Natural Gas
Feasibility: in research stage; production requires solution to technological problems and economics; estimated development is hard to forecast, but appears to be moderately remote potential.
Efficiency of use: unknown, as significant quantities of energy (nuclear) are required for production. Use efficiencies as per natural gas.

Environmental Factors:
Production: Land use disruption and damage in blasts; minute amounts of radioactivity in krypton. Potential radioactive pollution of ground water; potential seismic triggering.
Transmission and use: see Natural Gas.

5. Coal-Electrical Generation

Uses: all uses of electricity
Feasibility: presently feasible; 110-150 year world supply of coal remaining if use trend continues. Four to six year lead time in siting, design and construction.
Efficiency of use: about 35% to busbar; maximum potential with improvements is about 39%. Losses in transmission vary, average about 6%.

Environmental Factors:
Mining: Land use (millions of acres), ecological damage, acid runoff, erosion; mine and waste fires, ground subsidence from underground mining.
Transmission to plant: by road, railway, slurry pipeline, with attendant impacts. Slurry pipeline requires water consumption (as water from slurry is highly polluted).
Production: emission of particulates (especially submicron size), SO_2, NO_x, CO_2, trace elements of toxic minerals and radioactivity. Land use, aesthetics, disposal of ash (can be disposed of in strip mine, but ground water may be affected.) cooling water consumption (15 acre-feet per MW), air and water thermal pollution, water pollution from scrubber bleed-off and cooling tower blowdown. Air pollutants are difficult to control. Land use; about 4 million acres now devoted to electrical generation; by 1990, 7 million more acres for 300 new 3,000 MW plants. (Rhode Island = 1 million acres.)

6. Coal Gasification

Uses: High BTU or low BTU gas can be produced, and can substitute for coal in power plants; low BTU gas can substitute for natural gas in many uses, and can be used in electrical power generation. See "Advanced Power Cycle" below.

Feasibility: A prototype is going to be constructed in New Mexico soon. Gasification by fluidized - bed discussion below). There are a number of various processes under development, and large commercial plants can be available by 1977. Current estimates of high BTU gas costs are 4 to 5 times present costs of coal for western power plants. The "Lurgi"

Exhibit 4

low BTU plant, using a gas turbine for electrical generator drive has been in operation in Europe for 30 years. Low BTU gasification appears competitive with coal if coal-fired plants must spend money on proper environmental controls.

Efficiency of use: not known

Environmental Factors:
Mining of coal
Transmission of coal to plant
Production: Low emissions of SO_2, NO_x, particulates. Emission of CO_2. Ash disposal. Water consumption, land use.

7. Advanced Power Cycle (APC)

Description: Basically, APC is a combination of components to achieve higher efficiencies and means of reducing pollution. EPA is studying one APC system consisting of a coal gasifier, a gas-clean-up element, a gas turbine, a boiler and a steam generator. Sulfur is produced as H_2S, which is much easier to remove than SO_2. Particulate removal is more effective than for conventional plants. Thermal pollution and CO_2 will be about half that of conventional plants per KW output.

Uses: base-load electrical power generation.

Feasibility: 500 MW plants by 1980, major use by mid-1980's.

Efficiency: 50% or higher.

Environmental Factors:
Mining of coal: see IA.5 above.
Transmission of coal: see IA.5 above.
Production: emission of SO_2 (ultimately, about 1/20 of that of conventional plants), NO_x (about 1/10 of that of conventional plants), particulates (significantly lower). Land use, disposal of ash, water consumption.

Costs to consumer of APC electricity may be 20% or more lower than conventional plants.
Transmission lines for electricity.

8. Advanced Combustion - Submerged Bed

Description - One process being studied by EPA is the use of an iron bath as a combustor for crushed coal. This is similar to the process for making steel. Coal and air are fed into a vat of molten iron. Hot gases released by the combustor heat steam in a boiler for driving a turbine and generator. Slag develops on top of the iron, and ash and sulfur are trapped in the slag which is removed.

Uses: electrical generation

Feasibility: A 100 MW demonstration plant could be on line in 3 years if funds were available. This process could be in major use by about 1980.

Efficiencies of use: not known

Environmental Factors:
Mining of coal, limestone
Transmission of coal to plant
Production: air emissions of CO_2, NO_x, unless pure oxygen is used in

combustor instead of air; almost no sulfur or particulate emission. Water for steam production. (Consumes limestone, produces sulfur and some iron.
Transmission lines for electricity.
Cost to consumer probably lower than conventional

9. Advanced Combustion - Fluidized Bed

Description: Air is passed upwards through a bed of granular non-combustible material such as coal ash or lime, causing the granular materials to become suspended. The air serves as combustion air for crushed coal or oil which is air-injected near the base of the bed. Hot gases produce steam in a boiler for turbine and generator drive, to produce electrical power. Advantages are: very high efficiencies of coal energy conversion, potentially high reductions of sulfur, NO_x and particulate emissions, lower capital and power costs, use of lower-grade coals, can use flue gases in APC system.

Uses: combustion-boiler for power generation and other industrial processes.
Feasibility: Great Britain is ready to build a 20MW prototype. EPA's goal is to prove the most efficient variations of this process by 1981.
Efficiency: Not known; probably high.

Environmental Factors:
Mining of coal, or production of oil.
Transmission of coal or oil to plant.
Production: small emissions of SO_2, NO_x, particulates; emission of CO_2. Consumption of water in steam generation. Mining of limestone. Ash disposal.

10. Magnetohydrodynamics (MHD)

Description: A MHD generator converts the kinetic and thermal energy of a moving plasma directly into electrical energy by passing a plasma flow through a strong magnetic field. Gas is superheated (4000° F) until it ionizes and is passed through the magnetic field, causing an electrical flow to occur. There are several concepts for MHD: open cycle plasma, closed cycle plasma and closed cycle liquid metal. In the latter process, plasma is replaced by liquid metal, and electrical currents are generated by its flow in a magnetic field. In the open cycle plasma process, "seeding" with potassium or a similar element is needed to create high conductivity, which is not needed with the closed cycle. The latter could use a nuclear heating source. In the open cycle plasma, MHD generation could "top" a conventional steam-turbine generator, increasing the efficiency. MHD would provide 1/3 of the power; steam would generate 2/3 of the power.

Uses: Electrical power.
Feasibility: R&D needed; estimated development about 1980 to 1985. Feasible production build-up thereafter unless unforeseen technological problems arise. Russians are constructing 75MW plant with MHD providing 25 MW, steam 50 MW. Generator performance and effective life are obstacles. Flue-gas cleaning in open-cycle

Exhibit 4

plasma must be improved to recover "seeding" material. Steam MHD may be feasible, using nuclear heating.
Efficiency of use: The MHD portion alone might be 55-60%; additional efficiency achievable if exhaust thermal energy used.

Environmental Factors:
Mining of coal: see IA.5 above.
Transmission to plant: see IA.5 above.
Power generation: unknown.

11. Fuel Cells

Description: Similar to space program fuel cells, in which hydrogen and oxygen combine to produce water and electricity, but using natural gas and air to produce water and dc electricity. Small "home units" could be used.

Uses: electrical power, in central or dispersed units
Feasibility: requires hydrocarbon gas (natural, coal, petroleum), hence relies on non-renewable resource. Is presently in research stage; demonstration probable in late 1970's.

Environmental Factors:
Requires gas; can be used in water-short regions. Produces CO_2 and waste heat (which may be usable).

12. Miscellaneous minor organic energy sources

Methane: natural, from sewage treatment, animal manure. Feasible and currently being used for small units. For example, some sewage plants produce more energy than they consume.
Wood: the most ancient fuel. Must be considered non-renewable, as it removes materials from natural cycle of decay and material cycling in ecosystem.
Vegetable and animal oils. (Don't count on whales much longer.)
Refuse: a ton of trash, generated at rate of 5.2 lb/day/person, contains about 10,000,000 BTU's (equivalent to 800 to 900 lb of coal).

B. Nuclear Fuels

1. Convential Reactor: water or gas-cooled, Thorium or Uranium 235 fuel, steam generation.

Uses: electrical generation; other uses for "waste" heat.
Feasibility: on line; many water-cooled plants in operation; 1000MW' High Temperature Gas Reactor (HTGR) being designed. England produces 12% of electrical power from nuclear plants. Cost to consumer is equal to or less than coal-fired plants, especially if the latter has proper pollution control devices. Eight to ten year lead time in siting, design, construction. Limited supplies of low-cost ores for U235.
Efficiency of use: 32%, with potential "multiple-use" of heat, including cooling water.

Environmental Factors:
Uranium mining; tailing control problems, including entry into watercourses.

Safety in shipment of uranium.

Production: minute amounts of long-lived radioactive tritium and krypton 85; possible severe disaster or minor incident from radioactivity (perhaps due to seismic activity); cooling water requirements about twice that of coal-fired plants, but Public Service of Colorado has 330 MW HTGR with closed-cycle cooling using towers and smaller amounts of make-up water (3%, or 900,000 gal/day/1000 MW).

Waste: processing and disposal of radioactive wastes with thousand-year half-lives, which must be stored in salt beds and which must not be permitted to contaminate underground waters.

"Waste heat" in cooling water can probably be used for agricultural irrigation or other purposes.

Uranium is non-renewable limited resource, with only about 30 years U.S. supply of low-cost U235 ores, not much longer life of world supplies.

Amount of fuel to be handled = 35 tons uranium dioxide vs. 2 million tons of coal for 1,000MW plant.

2. Breeder reactors.

Description: Breeder reactors, such as Liquid Metal Fast Breeder Reactor (LMFBR) and Gas-Cooled Fast Breeder Reactor (GCFR), uses plutonium and uranium 238, which is 140 times as plentiful as U235. It produces a net gain of half an atom of fissionable plutonium for every 1.5 atoms of uranium used; hence, it "breeds" new fissionable fuel. Liquid sodium, salt or gas transfers heat for steam generation, which drives turbine and generator.

Uses: see IB.1 above.

Feasibility: Three firms have proposals to AEC for 300 KW test plants. Russia, England and France are building demonstration plants. Probably not available for massive use until 1990. The AEC apparently is not interexted in the GCRF, although some scientists favor its development.

Efficiency: not known; not critical except in terms of condensate water.

Environmental effects:
See IB.1 above.
Fuel supply adequate for 20,000 to 60,000 years or more.

3. Fusion

Description: Confinement of heavy isotopes of hydrogen (deuterium and/or tritium) at sufficiently high temperature and density will result in the fusion of these isotopes to produce heavier elements and a large amount of energy, which can be converted to electricity. Fuel is abundant in sea water. Higher efficiencies are possible if "topping cycles" (additional energy conversion cycles) are used, and the chance of a nuclear excursion is eliminated. The heavier elements will be helium and hydrogen.

Uses: Heat to generate electrical power.

Feasibility: It will be about five years before researchers will be able to commit themselves to certainty that fusion process is feasible for significant amounts of energy. Much R&D on engineering and science will remain. Fusion appears to be at least 20 to 30 years away.

Exhibit 4

Environmental Factors:
Less hazard and radioactivity release than conventional fission plant. No mining or waste disposal

C. Natural non-depletable sources.

1. Geothermal

Description: In certain regions, heat from the magma of the earth's mantle, under the cool outside crust, is closer to the earth's surface and in sufficient quantities to heat underground water in porous and permeable rock. This heating is often great enough to produce steam. Hot springs are natural examples of geothermal water flows. By ordinary well drilling, geothermal steam or hot water can be brought to the surface. It can be used to drive turbines for electrical generation or for residential or industrial heat.

Uses: electrical generation, heat for hot water.
Feasibility: Immediate. One plant in California has 82MW of electrical generation on line, 330 MW more under construction, and 2 to 5 thousand MW potential in the geothermal field. Mexico, Japan, Hungary, USSR, Iceland and New Zealand are all producing electricity from geothermal sources, as well as producing hot water. Estimates of available power range from 30,000KW to 100,000MW (present installed generating capacity in U.S. is 300,000MW). Problems exist in exploration, and power must be transmitted to load centers. Potential geothermal fields about 1/3 to 1/2 of the West. Costs of electricity to customer might be 2/3 that of coal-fired plants. Probably 4-5 year lead time from start to on-line of plant.
Efficiencies: vary; moderately low to medium.

Environmental Factors:
Production: wells, land use. Emissions of small amounts of methane, hydrogen sulfide, (which is easily controlled).
Transmission: power lines.
Comment: Nuclear detonations to create subsurface cavities at great depths for geothermal reservoirs is being considered by the AEC. Environmental effects are unknown, but will involve some radioactivity.

2. Hydroelectric Power, including Pumped Storage.

Uses: generation of electrical power, especially good for peak power.
Feasibility: In use. About 35% of world potential, two-thirds of U.S. potential has been developed; accounts for 3.9% of U.S. energy conversion. Lead time in dam planning and construction is usually at least a decade. Pumped storage requires two reservoirs. During off-peak hours, electricity is used (from another source) with reversed turbines to pump water from lower to higher reservoir, where it can be used to generate power during peak periods. Economics limit its use.
Efficiency: high

Environmental Factors:
Damming of rivers and change of flow. Unfortunately, the same physiographic features which make good dam sites also make for scenic beauty and wilderness qualities. Dams cause thermal changes, evaporative losses and salinity concentration increases, [illegible] saturation of nitrogen in water, changed land use, inundation of

Exhibit 4

wildlife habitat, etc., etc. Pumped storage is a fairly good energy storage system.

3. Solar Energy

Description: several different means of capturing and using the sun's heat radiations for energy are in use or are possible. One type uses cells on individual houses or in small units to heat hot water, which can be stored. A proposed massive system would involve a 75 mile square, with solar heat being absorbed, stored in liquid metal, used to generate 1,000,000 MW of electrical power. A third possible method is a synchronous-orbiting satellite with photovoltaic cells of 25 square miles, with microwave energy relay to earth. A fourth method uses photovoltaic cells at the earth's surface. Solar heat radiation induces an electrical flow in photovoltaic cells. This is used in the space program, but presently is extremely expensive. A fifth proposal is a large solar concentrator-converter.
Feasibility: Presently, economics hinder wider use. "Primitive" technology is available. A five-to-ten year lead time for large demonstration plants seems reasonable.
Efficiency: 10%, with 20% as a goal.

Environmental Factors:
Land use: large areas of land will be required for "heat farms."
Transmission: by wires.
Probably the "cleanest" and least depletable energy conversion process possible.

4. Ocean Power.

Description: Tidal flows are presently used to drive turbines and generators in one large estuary in France. Floating wave-power plants are a concept.
Uses: generation of electrical power.
Feasibility: Tidal-flow turbines are in use, but economics of construction is unfavorable.
Efficiencies: not known.

Environmental Factors:
Not known; some effect on estuaries from tidal plants, probably highly disruptive of natural estuarine ecosystem.
Aesthetics.

5. Wind.

Description: remember the windmill? Unfortunately, the wind doesn't blow all of the time. Could be used with (improved) storage batteries, for small scale electrical power.
Uses: Local electrical and mechanical power.
Feasibility: Limited, but available now. Economics not known.

Environmental Factors:
Can windmills be as ugly as transmission lines? (See Holland.)

Exhibit 4

6. Hydrogen

Description: Liquid hydrogen is used as a fuel in rockets, and has tremendous energy potential. Potentials, feasibility, uses and environmental factors have not been adequately studied.

II. Alternatives in Transmission and Storage

Discussion: The mode of moving energy from source to conversion point to point of use, and combinations of modes, give a range of alternatives with varying environmental impacts. Decisions are usually based almost completely on economics, which is affected by the technological state-of-the-art. Better decisions will consider environmental factors to develop a better mix of modes and siting. Also, energy losses in transportation are considered in economic terms; environmental factors of losses should be considered, and to the maximum extent, efficiency (or minimization of energy losses) should be a paramount determinant as well as direct costs of losses.

Environmental factors include spillage, safety hazard, aesthetics, effect on biota, land use, air and water pollutants and thermal changes, effect on recreation and cultural values, potential hazard to service continuity, and other factors.

Storage is a factor in the time-quantity aspects of energy movement. Pumped hydroelectric power has been mentioned as one form of energy storage. Electric batteries are another. Storage is important also in enabling best utilization of "clean" conversion modes, some of which rely on intermittent natural process, or which are not suited to peaking problems without storage.

Following is a brief outline of storage and transmission modes, with limited discussion of certain considerations.

A. Storage

1. Hydro-electric. See pumped storage in Section I.

2. Batteries: The lead-acid storage battery used in automobiles is an example. R&D is being performed to increase storage capabilities. Problems exist in amount of energy stored and release rates, charging rates, cost, and safety, especially for use in cars. Some of the potential battery types operate at fairly high temperatures, such as lithium-chlorine battery at about 600°. Other batteries are nickel-cadmium, nickel-zinc, silver-zinc, organic-electrolyte, zinc-air, and sodium-sulfur. Battery efficiency is 80% or higher, so there are energy losses in storage. World supplies of some of the metals are very limited.

3. Heat storage: hot water, molten metals, and solid materials can be used. At present, low use factors of capital investments in heat storage make them uneconomical. This does not imply that there is no future for heat storage; limited applications should be feasible if the storage is integrated into a production-transmission-storage system. Molten metal takes advantage of the latent heat of liquifaction; to liquify a material requires an input of heat with no change in temperature; this heat is released when the material solidifies.

Exhibit 4

4. Mechanical storage: flywheels can be used to store energy in stationary and mobile situations. R&D is needed, but a good potential exists.

B. Transmission

1. Obviously, energy is transmitted in gas, liquid and solid form by land and water. Ships, barges, trains, trucks, pipelines are all used. The decisions are usually based on economics and on physiography (i.e., oceanic shipment means ships, not trains or pipelines).

2. Electrical energy is transmitted by wire. Current technology limits AC voltages to 345 KV. Future voltages may be as high as 1300 KV. Direct-current transmission is economically competitive in high voltages at distances of 400 miles or more; capital investment in conversion stations is the primary factor in this. There are still problems in reliability of high-voltage DC transmission, and R&D is needed.

Greater energy transmission per corridor is possible. For example, per square foot of corridor space:

345 KV AC permits 47 KW/ft^2
735 KV AC permits 61 KW/ft^2
1300 KV AC permits 94 to 400 KW/ft^2, eventually.

Comparing AC and DC for equal Right-of-Way:

AC		DC	
KV	MW	KV	MW
230	240		
345	580	300	900
500	1,280	500	2,500
765	2,700	700	4,500
1,300	6,500	1,000	8,000

Undergrounding of cables is always of interest to the public for environmental interest. Currently, total capital and M&O costs are 5 to 15 times higher for high-voltage underground transmission. Research is being done in insulation (including gas insulation), cryogenics for very high conductivity, and other factors. There are a number of technical problems.

Grids of transmission systems transfer power, and are especially important in meeting peaking demands. Improved grids can reduce the amount of facilities for production of energy by providing better utilization of facilities. It appears desirable to delay any massive grid development until additional R&D is accomplished, so that the future grid can use advances in technology. Perhaps 6 years of R&D and 5 years of grid development might be reasonable.

"Utilidors" should be developed in urban and non-urban situations. The "utilidor" is a utility corridor, in which transportation, communications, energy, gas, water, wastes and other materials are moved. Space and land use utilization, aesthetics, cost, and potential for waste heat recapture are justifications for utilidors. Europeans are way ahead of this country in developing utilidors.

Exhibit 4

3. General comment: at present, it is just as economical to ship coal as it is to transmit electricity from power plants. Energy efficiency appears greater for bulk coal shipment (97% by train vs. 90% for electricity transmission); i.e., energy losses are higher for mine-mouth generation and wire transmission.

Environmental problems exist in any form of energy shipment or transmission. Perhaps the greatest concern at present is associated with petroleum production and shipment, with oil spillage. Both continuous small amounts (0.1% of shipped oil) and potential supertanker disasters are involved. In the Atlantic, Jacques Cousteau figures that the damage to the ocean is already 30% to 50%.

Proper planning, design, location and controls are imperative to minimize environmental damage.

III. Alternatives in Consumption

Following are a few general comments.

A. Efficiency in Consumption.

1. Transportation. Transportation consumes about 30% of our energy in direct use, and about 10% more in indirect use (refining, asphalt, production of transportation equipment, etc.).

In direct consumption, efficiency in terms of BTU's per passenger miles for various modes is as follows:

Fast train	980
Subway train	1700
Large bus	1000
Car (1.2 people)	7300
747 Jet	5900
SST	9500

In cargo, large pipelines and supertankers deliver 800-1000 ton-miles per gallon, freight trains 100-300, trucks less than 100. In terms of total consumption, automobiles account for the great majority of energy consumption. Efficiency of energy conversion for the car is about 12%; electrical cars could achieve a 20% efficiency from energy source to use.

It is readily apparent that mass transit, smaller and more efficient cars, increased pedestrian and bicycle use, and a number of steps can and must be taken to change transportation efficiencies and reduce consumption. For example, the "Single Urban Fund" proposed by the Secretary of Transportation would permit the use of gasoline taxes for mass transit development. Unfortunately, the proposed $1 billion per year is 1/4 of what is needed, and as constituted, only the very large cities would benefit.

2. Consumption in residential-industrial uses: There are considerable opportunities in better building design to reduce heating loads (by 20% with better insulation), avoid air-conditioning, and improve the use of natural light.

Efficiencies exist in every aspect of consumption, including refrigeration, industrial production, and other uses. The problem must be attacked through R&D, building codes, better engineering, and other means.

Exhibit 4

3. "Waste" heat was discussed in conversion alternatives; opportunities exist in consumption also, but will not be discussed in detail herein.

B. Controls of Consumption

1. Rationing-electricity, gasoline, gas.
2. Education of consumers
3. Pricing: basically, all costs should be internalized. New users bear entire cost of new energy. Surcharges in peak months. Inverse pricing (the rate increases with use). Elimination of all subsidies such as subsidized water, depletion allowances. "luxury" taxes: air conditioning, non-necessary uses. Pollution taxes to producers (to internalize costs).

4. Utility companies change profit and compensation system (from return on on investment). Restrict advertising.

5. Interruptible service to industry to reduce peak loads.

IV. Alternatives in Land Use

A. Generation location.

Past practice has located generation facilities near load centers. Cheaper high voltage transmission and increasing pollution control costs for load center plants have led to the mine-mouth location in the case of coal. There are better alternatives and combinations of components of the system than those proposed in the Southwest and North Central power studies.

Generation of power and heat can be at:

Load Center
Central plant
Individual Units
Energy source
Anywhere in between (limited primarily by cooling water; this limit can be reduced if flow-through water cooling is not used).

New thinking can be utilized. Cooling water could be irrigation water, used and returned to irrigation. Industrial cities should eventually be developed to use every bit of presently wasted heat and material, and should be located at power plant sites. These need not be at energy resource locations, because coal or other energy can be shipped to the plants as cheaply as power can be transmitted by wire.

Transmission systems should be based on land use factors, and should use the utilidor concept.

B. Resource Development.

There are some commercial resources which should never be touched because very high environmental values will be destroyed. Furthermore, there are priorities in developing other resources. Those which conflict with the natural high-value areas should at least be left as options for future generations. Those resources which force the development of other resources, such as water, new roads, new towns, should be low priority. Strippable coal should not automatically

be given high priority, but should be restricted by governmental action and released for use by government, in the general welfare. Complete land reclamation must be practiced.

Comments

1. "Land use" in environmental factors has a number of ramifications. Loss of arable land, vegetation, wildlife habitat, open space are involved. Impacts on watershed and ground and surface water may be involved. Aesthetics is always affected. In some cases, such as land use for oil refineries, economics and technological factors cause especially unpropitious land uses, such as refineries in estuarine areas or near deep-water tanker unloading facilities.

2. Water consumption has attendant ecological damages: reduced stream flows; increased concentration of dissolved minerals; dams and reservoirs in many cases; thermal changes to streams, and others. Pollution can be reduced by evaporation of water from blowdown, scrubbers, etc., but this increases consumption and harms river flows, salinity, etc. Pollution could be reduced by tertiary treatment with less consumption.

3. Alternative uses of resources has not been emphasized in this treatment. For example, petroleum for lubrication is presently essential for industry, transportation and household use. Lubrication presently accounts for 0.8% of net energy input in U.S. Vegetable oils could substitute in the future, but the amount of land required and inputs of water, fertilizers and production facilities could be a significant problem.

   Coal is a potential food source, as an alternate use. Water as many alternate and multiple uses, including cultural and aesthetic uses, but it is a source of energy and is necessary in energy conversion.

4. Other resources and capital involved in energy production/transmission have not been portrayed. A power plant requires cement, steel, copper and other metals which are increasingly scarce or of lower grade ores, etc. All of these materials require natural resources and energy in their production and fabrication, with attendant environmental effects.

5. Pollution control feasibility and cost is a major aspect of alternatives, and this has not been displayed in the itemization above. In general, particulate emissions, SO_2, NO_x and CO are difficult and expensive to control, and synergism is a problem in both control and effects. In coal-fired power plants, for example, electrostatic precipitator removal of particulates is more efficient with high-sulphur coal. Carbon monoxide control in internal combustion engines and NO_x controls are inverse, if control is attempted through compression ratio and combustion control.

   In effects, SO_2, particulates and NO_x all act synergistically on biota and on visibility.

6. Base load and peaking load generation of electricity are separable problems to an extent. Certain technologies are well suited to continuous base load power generation but not as well suited to peak load generation.

7. Research and development funding and time schedules are a major point of contention. It must be recognized that adequate funding ca[illegible] ess

an R&D timetable to a certain point. However, examples in foreign countries indicate that successes are possible and that America lags badly in many respects. This is partially due to U.S. emphasis on military and space research, partially due to reliance on private industrial research. It is obvious that U.S. R&D investment must be greatly accelerated. Electric power companies recommend $10.9 billion on R&D on present methods of generation ("because of heavy industry-wide investment in present day equipment") in the next 29 years, and only $731 million for new non-nuclear technologies (Solar, MHD fuel cell, etc.) in about the same period. Nuclear R&D funds are proposed at $8.4 billion, over 29 years, with major expenditures star ing in 1980. It is highly probable that the public will be better served by R&D which does not perpetuate present generation technologies but which brings new technologies on line as soon as possible. These power companies recommend no Federal investment in geothermal energy, for example. Similarly, power companies recommend major R&D on present methods, minimal funding for new technologies (such as very high voltage AC, DC, undergrounding, etc.).

8. Waste products can be reduced and power costs lowered by efforts to use wastes as by-products. For example, some minerals are recoverable from ash, and ash itself can be used in concrete for and other purposes. Economics presently impedes progress, but more research and positive programming is needed. Siting is important. For example, plant location in remote areas hurts the economics of ash or sulfur use because of shipping costs.

Exhibit 4

United States Department of the Interior
BUREAU OF INDIAN AFFAIRS
NORTHERN CHEYENNE AGENCY
LAME DEER, MONTANA 59043

RECEIVED
FEB 20 1973
ENVIRONMENTAL
DIV.

IN REPLY REFER TO:
Administration

February 13, 1973

Mr. Dan Vichorek
State Department of Health
Coswell Building
Helena, Montana 59601

Dear Mr. Vichorek:

Per our telephone conversation relative to the Colstrip Power Plant, I have discussed this with Mr. Allen Rowland, Tribal President. He is planning to share his thoughts also. I submit the following comments on the subject:

1. The Northern Cheyenne Tribe is definitely concerned over the proposed construction of the power plant at Colstrip. They see this as having a decided negative effect upon the environment of the reservation.

2. There will be a "splash over" effect of influx of people into the Colstrip area. Already, with Peabody Coal and Western Energy mining operations, the influx of people is felt at Lame Deer. A number of employees of these companies do reside on the reservation--these are employees who are not members of the Tribe and who are non-Indian. With the construction of the power plant in full operation, we can anticipate greater numbers desiring to reside here.

3. The power plant will create a pollution problem as it will release fly-ash as well as other emmissions which will be carried to the reservation. The normal wind direction is from Colstrip to the south and the reservation is located in that general area.

4. The Tribe is concerned about the effects of pollution on not only natural resources, i.e. timber, water, etc., but upon humans. Also, the effects on wildlife and other game will be negative. This is of great concern to the Tribe.

5. The Tribe anticipates heavy use of its recreation areas by non-Indians. The Tribe is not prepared to handle this degree of influx. Also, this could create some very real jurisdictional and legal problems.

6. Certainly, with more people moving into the area, traffic by vehicular means will be greatly increased. This will create problems for the reservation and its people.

Exhibit 4

7. Finally, the Tribe is concerned about the loosely and nebulously worded draft impact statement that has been circulated. There are too many unanswered questions contained within that document; insufficient or inadequate responses to questions raised by the writers of that document, etc. It is hoped that a more complete and comprehensive study be made before the permit to construct is issued.

In conclusion, the Tribe is concerned that little or no attention has been given to their views on the proposed plant. The Tribal Council, as the highest governing body of the reservation had not been contacted prior to your telephone call.

Sincerely yours,

Alonzo T. Spang, Sr.

Dr. Alonzo T. Spang, Sr.
Superintendent

Department of Health and
Environmental Sciences
Helena, Montana

Attention: Mr. Donald Holtz

Dear Dr. Anderson:

The draft environmental impact statement and draft supplement on the proposed Montana Power Company electrical generating plant at Colstrip has been reviewed by the EQC staff, prompting the ensuing comments.

Page 2--paragraph 2. The pipeline diameter and maximum water diversion figures presented here, in the supplement, and page iv are significantly smaller than those in Montana Power Company's Notice of Appropriation [3] (22"-26" vs. 60" and 8,000 gallons per minute vs. 112,200 gallons per minute). A more definite commitment as to size of pipeline is needed to assess the possible future environmental impact on the Yellowstone River due to water withdrawal. (See comments on water quality impact).

Page 4--paragraph 1. A recent environmental assessment on a proposed mobile home park at Colstrip, prepared by the Environmental Services Bureau of the Department of Health, indicates that at least a portion of the 800-900 man construction work force will live in the Colstrip area. The assessment states that "The immediate population (of the trailer court) is likely to consist of temporary area residents whose interest is construction employment. Too often this transiency precludes care of housing and premises and little aesthetic improvement is undertaken."

The assessment further states that "...the immediate effect (of the total complex) is likely to be a tendency toward a boomtown environment, especially during the construction phase. Unless carefully controlled, spin-off service type business could develop indiscriminately with an eye to operation during the boom phase only. This practice leads to hastily, improperly and cheaply constructed establishments which are abandoned when their profits decline."

Exhibit 4

There was apparently little or no coordination between the Environmental Services Bureau and the Air Quality Bureau in assessing the impact accruing from the influx of construction workers. Furthermore, neither Environmental Services' assessment nor Air Quality's impact statement adequately discussed the full range of ramifications possible, including social and economic, due to the total temporary construction work force.

Page 8--paragraphs 3 and 4. Perhaps more pertinent to local ambient air quality than a description of a modified continental climate would be a discussion of local meteorological conditions, including prevailing wind direction and velocity, inversion strength and frequency, the relationship between seasonal weather patterns and contaminant concentration levels, and the probable behavior of plumes with respect to local topography. It is possible much of this information is now available from the meteorological assessment being conducted for the applicant by Montana State University.

Page 12--paragraph 1. Some discussion should be presented here on the adequacy of the diffusion model and why this model was chosen over others that may be available. Has this model proven accurate in past applications?

Page 19--paragraph 3. The statement that uranium and thorium will be removed from the effluent gases suggests that these elements will be present in the fly ash. If so, in what concentrations are they likely to occur? Also, has uranium and thorium removal from effluent gases been demonstrated in existing installations?

Pages 25,26--parts D,1.b.,c. It is reasonable to assume that the preponderance of the water soluble components of the ash will be extracted and concentrated in the water of the ash ponds before the ash is removed to be buried in the mines. It is therefore conceivable that groundwater contamination could result from percolation of highly charged mineral water into the subsurface reservoir. Is such contamination likely? If so, what provisions have been made for sealing the bottom of the reservoir? If contamination is not likely, mention should be made of this fact.

Page 29--paragraph 4. The changes in water quantity due to diversion from the Yellowstone River can be quantified, and changes in water quality due to this diversion can be predicted, at least intuitively as to the types of changes to be expected. The degree to which these changes would take place is in the realm of speculation.

According to statistics supplied by MPC the proposed plant would consume 8,000 gallons per minute or 17.8 cubic feet per second (cfs). Records from the Rosebud County clerk and recorder's office indicate that the total MPC appropriation from the Yellowstone River is 250 cfs. [3]

These two figures, 17.8 cfs and 250 cfs, can be compared with selected Yellowstone River discharge figures to yield the proportion or percentage of river water diverted from which estimates of impact on water quality may be approximated. The following selected discharge figures were measured by the U.S.G.S. at station 3090 on the Yellowstone River at Miles City. [4]

Exhibit 4

1. 996 cfs (December 14, 1932). Minimum discharge for period of record.
   17.8 cfs = 1.8%
   250 cfs = 25%

2. 1400 cfs (May, 1961). Minimum discharge for water year 1961.
   17.8 cfs = 1.3%
   250 cfs = 18%

3. 2290 cfs (January 7, 1970). Minimum discharge for water year 1970.
   17.8 cfs = 0.8%
   250 cfs - 11%

4. 11140 cfs. Average discharge for 43 years of record.
   17.8 cfs = 0.2%
   250 cfs = 2.2%

From the foregoing it is clear that water diverted for and consumed by the proposed plant (17.8 cfs) would be inconsequential in terms of the total flow of the Yellowstone past Miles City, even at minimum discharge levels. The additive effect of several more plants drawing water from the same source may be considerable, however.

Assuming utilization of the total appropriation of 250 cfs, proportionate use of Yellowstone River water would range from 11% to 25% at minimum discharge levels and 2.2% of the 43-year average discharge. For those who would contend that this is an unrealistic figure because appropriations are usually far above what is actually diverted and used, the Appraisal Report on Montana-Wyoming Aqueducts[2] lists approximately 2,350 cfs (1,700,000 acre-feet per year) of Yellowstone River water subject to development as industrial water supplies and a recent newspaper editorial[1] written by a Bureau of Reclamation official indicates that in normal years the flow of the Yellowstone would be reduced one-third and in a dry year the flow would be reduced about one-half as a result of water diversion for industrial use.

The diversion of water of the magnitude discussed in the paragraph above would have effects on the water quality of the Yellowstone River in the following areas:

1. Temperature. Loss of water volume and buffering capacity would result in more erratic temperature fluctuations, higher temperature maxima and more prolonged periods of freezing, thus affecting:
   a. life histories of fish, invertebrates and aquatic plants.
   b. growth and reproductive rates of preferred and undesirable fish species, possibly giving the latter a competitive advantage and resulting in changes in
   c. relative abundance of preferred and undesirable fish species.
   d. growth rates of aquatic plants, including algae; possibly enhancing seasonal production resulting in nuisance blooms and taste and odor problems.

Exhibit 4

e. diversity of the aquatic community.

2. Concentration of Pollutants. Most water quality management plans are based on the dilution effect afforded by the receiving waters. Once a substantial volume of dilution water is removed polluters may find themselves in a position of noncompliance with existing water quality criteria. Parameters, the concentrations or levels of which may be affected, include:
   a. coliforms.
   b. biochemical oxygen demand (BOD) and dissolved oxygen.
   c. pH
   d. turbidity.
   e. temperature.
   f. residues.
   g. sediment or settleable solids.
   h. toxic substances (pesticides and heavy metals).

   In the extreme case, one or any number of these factors may increase (or decrease) in value or concentration to the point where the tolerance level of fish and bottom organisms is exceeded and community diversity is thereby reduced.

3. Concentration of Nutrients. Nutrients, particularly phosphorus, nitrogen and carbon, are critical to growth of algae and other plants which form the base of the aquatic food chain. Only slight increases in the usable concentrations of these three strategic elements, alone or in combination, are often enough to trigger massive algal growths or blooms which could degrade the water aesthetically by causing taste and odor problems and visual unsightliness. The Yellowstone River, however, is not subject to this type of problem except where it or its confluent the Missouri may be impounded.

These are three areas where water quality would be affected by diversion away from the river. These are merely the types of problems that may arise; statements on their extent would be speculation at this time. The severity of the impact would be determined by the magnitude and timing of the withdrawal. Critical parameters should be monitored over a period of years to detect undesirable changes as development progresses and more water is appropriated, withdrawn and consumed.

Page 37--Section VI. Possibly here or under the description of the proposed action should be presented some information attempting to justify the need for this plant in this location. The applicant should be able to substantiate Montana energy needs by supplying information on the following evaluative criteria: (1) growth in demand and projections of need; (2) socially beneficial uses of the output of this facility, including its uses to protect or enhance environmental quality; and (3) conservation activities which could reduce the need for more power.

Also desirable would be an informative discussion on why the plant is being located here rather than at the load center.

Exhibit 4

Page 45--list of contributors. Although an impressive list of credentials is presented here, the Department of Health has other specialists, such as water pollution and noise specialists, who could have added substantially to the impact analysis. Also, the impact analysis can hardly be considered complete without the input of either a social scientist or a life scientist.

Supplement--Dry Cooling Towers. Additional information on the costs of wet versus dry cooling might be obtained from a recent article based on work conducted out of the EPA Northwest Water Laboratory, Corvallis, Oregon.[5] This article concludes that "...whenever the competitive demands for other water uses put a high enough cost on its use for cooling, the dry system may well become an economically attractive alternative to evaporating cooling systems."

We hope these comments will be helpful in constructing your final impact statement and making your decision on the Colstrip power plant. Thank you for your efforts toward compliance with MEPA and the EQC guidelines.

Sincerely yours,

FLETCHER E. NEWBY

STATEMENT PRESENTED AT THE PUBLIC HEARING ON THE DRAFT ENVIRONMENTAL IMPACT STATEMENT ON THE PROPOSED COAL-FIRED ELECTRICAL GENERATION FACILITY TO BE CONSTRUCTED AT COLSTRIP, MONTANA BY MONTANA POWER COMPANY, JANUARY 5, 1973.

I AM FLETCHER NEWBY, DIRECTOR OF THE ENVIRONMENTAL QUALITY COUNCIL, ESTABLISHED BY THE MONTANA ENVIRONMENTAL POLICY ACT (MEPA) OF 1971.

THE ENVIRONMENTAL QUALITY COUNCIL WAS CREATED BY THE LEGISLATURE TO PROVIDE A POLICY OVERVIEW OF STATE AGENCY ACTIONS WITH ENVIRONMENTAL CONSEQUENCES AND TO ADMINISTER THE ENVIRONMENTAL IMPACT STATEMENT PROCESS. IN ADDITION, THE COUNCIL HAS BEEN INSTRUCTED BY THE ACT "TO REVIEW AND APPRAISE THE VARIOUS PROGRAMS AND ACTIVITIES OF STATE AGENCIES" IN THE LIGHT OF THE ENVIRONMENTAL POLICY TO DETERMINE THE EXTENT TO WHICH SUCH PROGRAMS AND ACTIVITIES ARE CONTRIBUTING TO THE ACHIEVEMENT OF THIS POLICY. IT IS IN THIS CONTEXT THAT THE COUNCIL IS INTENSELY INTERESTED IN THE DECISIONS AND ACTIONS OF THE BOARD AND THE DEPARTMENT OF HEALTH AND ENVIRONMENTAL SCIENCES AFFECTING ENVIRONMENTAL QUALITY.

MEPA IMPOSES A LEGAL DUTY ON STATE AGENCIES TO CONSIDER ENVIRONMENTAL VALUES IN THEIR DECISION-MAKING PROCESSES. AGENCIES WHOSE MANDATES PREVIOUSLY DIRECTED THEIR ATTENTION ONLY TO CERTAIN FACETS OF THE ENVIRONMENT NOW HAVE A RESPONSIBILITY AS BROAD AS THE ENVIRONMENTAL POLICY DECLARED IN MEPA. WHERE AN AGENCY PREVIOUSLY LOOKED AT ONLY A LIMITED ASPECT OF PRIVATE ACTIVITIES UNDER ITS REGULATION, MEPA FORCES IT TO BROADEN ITS CONCERNS

Exhibit 4

SUBSTANTIALLY. AN AGENCY MUST CONSIDER, AND AS APPROPRIATE, ACT TO MINIMIZE THE ADVERSE ENVIRONMENTAL EFFECTS THAT CAN BE EXPECTED FROM THE ACTIVITY SUBJECT TO ITS REGULATORY ACTION.

MEPA IS CLOSELY MODELLED UPON ITS FEDERAL PREDECESSOR THE NATIONAL ENVIRONMENTAL POLICY ACT (NEPA). FOR THIS REASON WE REGARD THE PRECEDENTS ESTABLISHED BY FEDERAL CASE LAW AS INSTRUCTIVE GUIDANCE FOR OUR OPERATIONS. IN THIS REGARD OUR TESTIMONY DRAWN FROM THIS BACKGROUND AND PRESENTED TODAY WILL PRIMARILY CONCERN PROCEDURAL MATTERS AS CONTRASTED WITH TECHNICAL COMMENTS, WHICH WE ARE SUBMITTING SEPARATELY, WE ARE AWARE THAT EXTENSIVE TECHNICAL COMMENT ON THE DRAFT ENVIRONMENTAL IMPACT STATEMENT HAS BEEN RECEIVED BY THE DEPARTMENT OF HEALTH AND ENVIRONMENTAL SCIENCES.

THE TWO PRIMARY PURPOSES OF AN ENVIRONMENTAL IMPACT STATEMENT ARE (1) TO COMPEL THE AGENCY TO CONSIDER THE ENVIRONMENTAL CONSEQUENCES OF ITS PROPOSED ACTION AND (2) THE ACCOMPLISHMENT OF FULL DISCLOSURE. THE ENVIRONMENTAL IMPACT STATEMENT IS NOT ONLY FOR USE BY DECISION MAKERS, IN THIS CASE THE BOARD AND THE DEPARTMENT OF HEALTH AND ENVIRONMENTAL SCIENCES, BUT ALSO MUST PROVIDE A BASIS FOR MEANINGFULLY ALLOWING THOSE WHO ARE REMOVED FROM THE DECISION-MAKING PROCESS TO EVALUATE AND BALANCE THE FACTORS ON THEIR OWN. THE STATEMENT MUST, AT A MINIMUM, CONTAIN INFORMATION WHICH WILL ALERT THE PUBLIC TO ALL KNOWN POSSIBLE ENVIRONMENTAL CONSEQUENCES. BECAUSE THE DRAFT SERVES AS A PRIMARY MEANS OF INFORMING OTHERS ABOUT THE ENVIRONMENTAL EFFECTS OF THE PROPOSED ACTION AND OF POSSIBLE ALTERNATIVE ACTIONS, IT SHOULD EMBODY A THOROUGH AIRING OF EACH OF THE POINTS SPECIFIED IN THE STATUTORY LANGUAGE OF MEPA. BY THE TIME IT CIRCULATES A DRAFT THE INITIATING AGENCY SHOULD

Exhibit 4

HAVE FULLY EXPLORED THOSE POINTS WITH HELP FROM OTHER SOURCES WHEN NECESSARY, RATHER THAN LEAVING PARTS OF THE ANALYSIS TO BE FURNISHED BY SOURCES OF COMMENTS.

WE BELIEVE THE DEFICIENCIES TO BE NOTED IN THE DRAFT STATEMENT ARE PRIMARILY THE RESULT OF ALLOWING INSUFFICIENT TIME FOR PREPARATION OF THE DRAFT AND FAILURE TO COMPLY WITH SECTION 69-6504(B)(1) OF MEPA WHICH DIRECTS AGENCIES TO UTILIZE A SYSTEMATIC INTERDISCIPLINARY APPROACH WHICH WILL ENSURE THE INTEGRATED USE OF THE NATURAL AND SOCIAL SCIENCES AND THE ENVIRONMENTAL DESIGN ARTS IN PLANNING AND IN DECISION MAKING WHICH MAY HAVE AN IMPACT ON MAN'S ENVIRONMENT. THE DRAFT STATEMENT WAS THE PRODUCT OF A CRASH EFFORT TO BEAT THE FIRST SCHEDULED DATE OF THE COURT HEARING. FURTHER, A GLANCE AT THE LIST OF PREPARATORS OF THE DRAFT STATEMENT REVEALS THAT ALL ARE PHYSICAL SCIENTISTS. NOTABLY LACKING ARE REPRESENTATIVES FROM ECONOMICS, LIFE SCIENCES, AND SOCIAL SCIENCES. IT ALSO APPEARS THAT THE EFFECT OF FULL DISCLOSURE WAS INHIBITED BY LACK OF COMPLETE INFORMATION FROM THE APPLICANT ON DEVELOPMENTS APPURTENANT TO THE POWER PLANT AND ON THE INTENDED USE OF THE ENERGY GENERATED BY THE PROPOSED PLANT.

THE ENVIRONMENTAL QUALITY COUNCIL, RECOGNIZING THESE DEFICIENCIES, AND AWARE OF SIGNIFICANT NEW INFORMATION, RECOMMENDED TO THE DEPARTMENT OF HEALTH AND ENVIRONMENTAL SCIENCES THE ISSUANCE OF A REVISED DRAFT OR SUPPLEMENT TO THE DRAFT. THE COUNCIL DID NOT RECOMMEND ANY CHANGE IN

Exhibit 4

THE PROPOSED TIME FRAME FOR THE HEARING AND RECEIPT OF COMMENTS. OBVIOUSLY THE PROCESS OF CIRCULATION AND COMMENT MUST END AT SOME POINT. THE COUNCIL'S SUGGESTION WAS NOT MADE WITHOUT PRECEDENT NOR WAS IT MADE LIGHTLY. AN EXCERPT FROM THE DECISION OF ONE DISTRICT COURT BEARS DIRECTLY UPON THIS SITUATION -- "IT IS DOUBTFUL THAT ANY AGENCY HOWEVER OBJECTIVE, HOWEVER SINCERE, HOWEVER WELL STAFFED, AND HOWEVER WELL FINANCED, COULD COME UP WITH A PERFECT ENVIRONMENTAL IMPACT STATEMENT IN CONNECTION WITH ANY MAJOR PROJECT. FURTHER STUDIES, EVALUATIONS, AND ANALYSES BY EXPERTS ARE ALMOST CERTAIN TO REVEAL INADEQUACIES OR DEFICIENCIES, BUT EVEN SUCH DEFICIENCIES AND INADEQUACIES DISCOVERED AFTER THE FACT CAN BE BROUGHT TO THE ATTENTION OF THE DECISION MAKERS."

IT SEEMS DESIRABLE TO PROVIDE SOME GUIDANCE AS TO WHAT IS EXPECTED IN THE FINAL ENVIRONMENTAL IMPACT STATEMENT. THE VERY RATIONALE FOR CONSULTATION WITH OTHERS IS THAT A COMMENTING AGENCY OR GROUP MAY UNCOVER ERRORS OR OMISSIONS IN THE DRAFT STATEMENT. THE FINAL STATEMENT, WHEN ISSUED, WILL THUS IDEALLY BE COMPREHENSIVE AND WILL GIVE ADEQUATE GUIDANCE IN THE AGENCY'S DECISION WHETHER TO GRANT THE PERMIT.

AN IMPORTANT CONSIDERATION IN PREPARATION OF THE FINAL STATEMENT IS ADEQUATE RESPONSE TO COMMENTS, INCLUDING

Exhibit 4

RESPONSIBLE OPPOSING VIEWS. WHAT IS INTENDED IS THE INCLUSION OF ALL MEANINGFUL REFERENCES THAT IDENTIFY THE PROBLEM AT HAND FOR THE RESPONSIBLE OFFICIAL. AGENCIES HAVE PUBLIC VALUES TO CONSIDER OTHER THAN THE ENVIRONMENT. BALANCING THEM AGAINST ENVIRONMENTAL VALUES IS IN INHERENT IN THE DUTY IMPOSED BY MEPA. IF THE ENVIRONMENTAL EFFECTS ARE ADVERSE, THE AGENCY MUST CONSIDER WHETHER THEY OUTWEIGH THE BENFITS OF THE PROPOSAL. THE IMPACT STATEMENT PROVIDES A BASIS FOR EVALUATION OF THE BENEFITS OF THE PROPOSED PROJECT IN LIGHT OF ITS ENVIRONMENTAL RISKS AND COMPARISON OF THE NET BALANCE FOR THE PROPOSED PROJECT WITH THE ENVIRONMENTAL RISKS PRESENTED BY ALTERNATIVE COURSES OF ACTION.

IN CLOSING THIS TESTIMONY IT SEEMS OBVIOUS THAT THE DESIRES OF THE PUBLIC AS COMMUNICATED TO THE DEPARTMENT OF HEALTH AND ENVIRONMENTAL SCIENCES ARE FOR A BROADER JURISDICTION THAN THAT GIVEN BY THE MONTANA CLEAN AIR ACT TO THE DEPARTMENT. THE GOVERNOR OF MONTANA, THE LEGISLATIVE COUNCIL, AND THE ENVIRONMENTAL QUALITY COUNCIL ALL HAVE RECOMMENDED A POWER PLANT SITING AUTHORITY ACT TO THE 1973 LEGISLATURE. IT MAY BE SMALL CONSOLATION TO THE DEPARTMENT OF HEALTH AND ENVIRONMENTAL SCIENCES BUT IF THIS ACT PASSES THE ENVIRONMENTAL IMPACT STATEMENT FOR THE COLSTRIP STEAM-ELECTRIC GENERATION PLANT MAY BE THE ONLY ONE OF THIS NATURE THE DEPARTMENT WILL EVER HAVE TO WRITE.

END.

ENVIRONMENTAL SCIENCES
DIVISION

Daniel Vichorek, Technical Writer
State of Montana
State Department of Health and
Environmental Sciences
Helena, Montana 59601

Dear Mr. Vichorek:

This letter contains answers to the questions asked in your January 2, 1973 letter. In addition to the specific information you requested, I am enclosing "20 Questions on Electric Power Loads and Resources in the Pacific Northwest", published by the Pacific Northwest River Basins Commission.

1. What is the rate of line loss in lines of various size, particularly 230-kv and 500-kv lines?

Strictly speaking, for a given line at 230-kv or 525-kv (commonly called 500-kv), and with a given conductor size, the percentage power loss per mile at half and full thermal loading is shown below:

Line Voltage (KV)	Conductor No. per phase	Conductor Designation	Power Loss/Mile Half Load %	Power Loss/Mile Full Load* %
230	1	Drake	.039	0.085
230	1	Pheasant	.033	0.073
525	2	Chukar	.014	0.029
525	3	Bunting	.015	0.033

* 50° rise above 25° c ambient, wind @ 1.4mph. (Max. design loading)

Because of system reliability considerations, BPA lines are normally loaded slightly below half the maximum design thermal rating. These lines would operate near maximum thermal loading only during emergency conditions.

The above information should not lead to hasty conclusions because power transfers through a transmission grid can result in great variations in losses, dependent upon many factors. Generally, the total power flow on a transmission system will result in the least possible losses. The effect of an incremental power transfer on transmission losses may either add or subtract to the existing losses, depending upon the direction of prior flows and the magnitude of the incremental transfer.

Exhibit 4

2. What corridor width is necessary for 230-kv lines? For 500-kv lines?

Each standard BPA right-of-way for both single-circuit and double-circuit, steel structure, 230,000-volt transmission lines is 125 feet wide. The right-of-way width for steel-structure 500,000-volt lines varies between 135 and 165 feet, depending upon the type of structure used. Enclosed for your reference is an information sheet entitled, "BPA's Single and Double-circuit 500 kilovolt Transmission Towers". You will note that tower 4 carries two 500,000-volt circuits which requires a right-of-way width of only 140 feet, whereas, tower 3, also carrying two 500-000-volt circuits, requires a width of 165 feet. The height varies inversly with the right-of-way width depending upon tower type; tower 3 is 143 feet high and tower 4 is 176 feet high. The reverse side of the information sheet shows various configurations of the transmission towers.

3. When two 230-kv or two 500-kv lines are run parallel, how close together may they be?

The minimum separation of two parallel lines is based on the required electrical clearance between the closest conductors. The necessary distance between centerlines is determined by several factors, the main ones being:

a. Line voltage - Higher voltage requires greater electrical clearance.

b. Tower design - This fixes the position of each conductor in relation to the tower center.

c. Span length - Longer spans allow more side swing of the conductor and, therefore, require greater separation.

d. Conductor design and tension - These factors also affect the amount that the conductors will sway horizontally.

The following figures are typical separations between centerlines of two parallel lines currently used by BPA:

230-kv, single-circuit, wood-pole	85 feet
230-kv, single-circuit, steel	115 feet
230-kv, double-circuit, steel	115 feet
500-kv, single-circuit, steel	115 feet
500-kv, double-circuit, steel	160 feet

4. How wide is the necessary right-of-way for parallel lines?

The right-of-way width requirements are based on most of the same factors mentioned above. The criteria for "edge distance" (distance from centerline of each line to the edge of the right-of-way easement) is that it must be great enough to provide for conductor side swing plus safe elec-

Exhibit 4

trical clearance. Typical right-of-way widths for two parallel lines are:

230-kv, wood-pole	185 feet
230-kv, steel	240 feet
500-kv, steel	250 feet

5. How much land would be impacted where a single or double 230-kv or 500-kv line crossed range or crop land? Does this include the service road?

The impact of towers on rangeland is minimal. Livestock graze under and around the structures. The only area permanently removed from use is an approximate five-foot square around each individual tower leg. This amounts to about 500 square feet per mile of line. Cropland is disturbed to a greater extent, both in the area removed from production and in inconvenience to the farmer in his activities. The cropland permanently affected by tower sites is as follows:

	Acres per Tower Site	Acres per Mile
230-kv, single circuit, wood-pole	.001	.007
230-kv, single-circuit, steel	.018	.090
230-kv, double-circuit, steel	.018	.090
500-kv, single-circuit, steel	.020	.10
500-kv, double-circuit, steel	.028	.14

Access roads create additional impacts which vary greatly with terrain. In fairly flat topography (less than 5% side slope), permanent road construction is usually not required on crop- or rangeland. Access can be along the right-of-way on the natural ground surface, with only minor and temporary construction. In steeper terrain the road system will cause more impact than the line itself. A typical access road through rolling farmland will disturb an area 20 feet wide, which amounts to 2.4 acres per mile.

6. What data exists on the use of the power to be exported from Montana?

I presume your question refers to the power to be acquired from the Colstrip development by Puget Sound Power & Light Company. This private company is a member of the Joint Power Planning Council which has formulated and is implementing the Pacific Northwest 10-year Hydro-Thermal Power Program. The Joint Power Planning Council is composed of 4 private utilities, 104 public utilities and BPA. The Hydro-Thermal Power Program is a cooperative regional effort to meet the total load requirements of the Pacific Northwest (which includes the Puget Sound Power & Light Company's loads).

The power that Puget is acquiring from the Colstrip development will not

Exhibit 4

likely to be used in aluminum reduction plants. It is reasonable to assume that the load-growth additions will be similar in nature to that which is presently served, and evaluating data contained in the Company's FPC report for calendar year 1971, energy was sold to the following classes of consumers in the indicated percentage:

Classification of energy delivered to ultimate consumers	Percent of sales
Non-farm residential	56.8
Commercial	21.7
Industrial	18.8
Street & Highway Lighting	0.6
All other	2.1
	100%

7. Since the demand for electricity is growing far faster than the population in the Northwest, what is causing the increased demand?

The enclosed paper on "Power Needs in the Pacific Northwest to 1990" explains in a fair amount of detail the fact that total energy use has been growing much more rapidly than population and electric energy use more rapidly than total energy use and the reasons therefore. The chart following page 6 has been revised and I have entered the revised years and percentage growth figures on the old chart since we have not reproduced a new one as yet.

8. What percentage of the power will go for industrial use, lighting, aluminum processing, home heating, or cooling?

The chart following page 11 in the aforementioned paper shows the relative amount of electric power used for residential space heating. It also indicates, in showing the difference between 1950 and 1970, the population growth accounted for only 4,345 million kwh of the over 22,300 kwh increase in residential use in the West Group Area (the geographic area served by BPA, less loads of Montana and Idaho Power Companies) between 1950 and 1970. The greatest increase, over 18,000 million kwh, came from increased use per customer and the largest single item, almost 8,000 million kwh, was electric space heat.

Also enclosed are two tables. The first shows electric power requirements by major consumer classes 1950 through 1990. The 1950, 1960 and 1970 data are taken from reports to the FPC and the 1980 and 1990 data are our estimates based on the West Group forecasts. The second table breaks down these sales data a little further. It shows industrial energy sales as a percent of total electric energy sales in the West Group Area and sales to the aluminum industry as a percent of total sales and industrial sales. Not only are industrial sales expected to decline as a percent of total sales, but aluminum sales as a percent of either total or industrial sales are expected to decline drastically over the next 20 years.

Exhibit 4

9. What, in laymen's terms, are "design corona losses" in power lines?

Transmission line corona is the electrical breakdown of the air in contact with the high-voltage conductors. It is confined to the conductor surface and is encouraged by rain. In anticipation of this phenomena, transmission lines are designed to minimize corona losses.

Corona loss may be likened to the small leaks in the wooden pipes used in early water systems. Wooden pipes have now been replaced with cast iron and this small water loss no longer exists. Hopefully, technology will advance to where we can also eliminate corona loss. The only methods presently known are uneconomical, so corona loss is minimized but not eliminated.

As in the case of water loss, corona loss reduces the amount of product available for the intended use. However, compared to the amount of product delivered, the loss is extremely small. Corona losses vary between 1-10 kilowatts per mile during fair weather, and 10-100 kilowatts during foul weather.

There are no adverse effects associated with normal line corona activity except for occasional radio and television interference.

10. How much power does BPA now import to Montana? How much is exported from Montana?

Some discussion on terminology may be in order before attempting to answer your question. The term "electric power" is a term used in the industry to mean inclusively "power and energy". Strictly speaking, the term "power" is the time rate of transferring energy, and "energy" is that which is capable of doing work. Power (often called "demand" when associated with loads and "capability" when associated with generation or power-handling facilities) is measured in kilowatts; electric energy is measured in kilowatt-hours. There are also two broad catagories of power -- firm and non-firm power. Firm power is intended to have assured availability and non-firm power does not have assured availability to meet load requirements.

During the 5 calendar years 1967 through 1971, BPA's total firm and non-firm energy sales in Montana have averaged about 4,351,600,000 kilowatt hours each year. The average annual energy actually generated at the Hungry Horse Project (the only Federal Project in Montana which BPA presently markets power from) has been roughly 950,400,000 kilowatt-hours. In terms of percentage, 78% of BPA's energy sales in Montana have been produced by generators located outside of the State.

Another term we often use is "average energy". This is determined by taking the total energy in kilowatt-hours, dividing by the total number

Exhibit 4

of hours in the period, resulting in a power (demand or capability) figure which if maintained throughout the period would transfer the total energy. The foregoing explanation allows me to express BPA's energy imports in a slightly different way. During the Fiscal Year 1972 (July 1, 1971 through June 30, 1972), BPA's average firm energy sales within our marketing area in Montana (West of the Continental Divide) was 418,900 kilowatts. These sales were to Cooperatives, 29,300 kilowatts; private utilities 145,100 kilowatts; Federal Agencies 4700 kilowatts; aluminum industry 302,400 kilowatts; and other industry (Stauffer Chemical Company) 36,400 kilowatts. In addition to these sales of firm energy, BPA sold 186,000 kilowatts average of interruptible power in Montana during Fiscal Year 1972, bringing the total to 604,900 kilowatts average.

The average firm generating capability of Hungry Horse Dam under critical water conditions is 221,000 kilowatts. A corresponding figure for Libby Dam, scheduled to begin generating in 1975, is 204,000 kilowatts. The total average firm generating capability of these two Federal Projects, with the power to be marketed by BPA is 425,000 kilowatts.

It must be recognized that the power flow situation is continually changing. For example, during the summer while Hungry Horse Dam is storing water, little or no power is being generated, resulting in most all of the energy BPA serves in Montana coming from outside the State. One of the uses of the new Dworshak (Idaho) - Hot Springs 500,000-volt transmission line is to carry the heavy power flow during the periods when Hungry Horse is not generating. Conversely during the wintertime when cold weather settles over the Pacific Northwest, the Hungry Horse Project will be generating at or near its rated peak generating capability of 285,000 kilowatts. The approximate peak demand of BPA-served loads in Western Montana during the Fiscal Year 1972 was 800,000 kilowatts.

On a state-wide basis, it appears that the generating sources within the State produce approximately 10 billion kilowatt hours annually, which is about the same amount required by the loads located within Montana. This statement is rough; no exhaustive study has been made. If you wish to pursue this further I suggest you contact the following organizations which operate generation and transmission facilities in Montana:

U. S. Bureau of Reclamation, Billings, Montana
Montana-Dakota Utilities
Montana Power Company
Washington Water Power Company.

I will be happy to provide generation and sales statistics for BPA-marketed power, if you wish to make such an analysis.

11. If Colstrip Unit 4 is built, what is the probable route of the 500,000-volt line out of Montana?

Exhibit 4

I am sure you recognize, assuming the Colstrip Unit 4 is built and that the private power company's desire to make use of the Federal Transmission System within the BPA marketing area, that the route for a 500,000-volt transmission line or lines can only be determined as a result of extensive studies. It is quite reasonable to assume the transmission facilities would connect to either or both Hot Springs Substation or Anaconda Substation. Both of these substations are strong power connection points in the transmission grid. On the west slopes of the Rocky Mountains the lines would probably either connect to existing facilities in the Spokane area or in the Lewiston area. Additional facilities from those areas westward would also be required. By referring to a topographic map, it is obvious that the number of mountain passes in Western Montana and Northern Idaho through which transmission facilities could be constructed are limited. To fulfill the intent of the National Environmental Policy Act of 1969, BPA will consider all available alternative corridors, if such lines are constructed.

12. Would new lines be necessary from Western to Eastern Montana?

I am certain additional lines will be required, both to serve loads in Montana and to provide a path for power to flow to the Northwest. We do not have any specific information available on what will be required, and you may wish to query the Montana Power Company in this regard.

13. What is the comparative cost of hauling the coal from Montana to generating plants near out-of-state load centers, and transmitting the power to the load centers from mine-mouth plants?

I do not have the answer. There would be some important judgment elements involved in such an analysis, such as probability of freight-rate increases. This would be of vital importance to Puget Sound Power and Light Company, and I suggest you make inquiry there.

Please let me know if additional information or clarification is desired.

Sincerely,

Ronald H. Wilkerson

Ronald H. Wilkerson
District Manager

COMMENTS OF THE ENVIRONMENTAL DEFENSE FUND
REGARDING THE DRAFT ENVIRONMENTAL IMPACT
STATEMENT ON THE PROPOSED MONTANA POWER COMPANY
ELECTRICAL GENERATING PLANT AT COLSTRIP, MONTANA

page 1.[1] Description of Proposed Action

The Venturi Scrubber Process was first patented in 1925 and put into commercial practice some 20 years later.[2] It is clear that this type of scrubber has certain advantages and disadvantages when compared with alternative methods of air pollution control. The Draft Environmental Impact Statement (DEIS) must deal with this subject in considerable detail. If there is evidence "that the Venturis will also remove most fluorides and trace metal compounds" such evidence should be cited and discussed. Past operational experience with Venturi Scrubbers and alternative modes of air pollution control is contrary to the optimistic outlook of the Draft Statement.

Pollution control technology, installed at the outset of operation at any given generating station, technically and economically tends to "lock in" the station for its usable life (35 to 50 years). It is imperative that the planned equipment be compatible with envisaged improvements in control technology, so that a retrofit of the generating station is not economically nor technically prohibited. This is particularly true in the case of coal-fired generating stations planned for rural regions with clean air, because it is likely that federal standards for atmospheric emissions of such stations will soon be made more stringent. Such changes in regulations are indicated by recent court interpretations of the Clean Air Amendments of 1970 and will apply to the proposed plant. If, as seems likely, the generating station under consideration is but the first in a series of plants to be operated at or near the same site, it will be critically important to plan for the maximum flexibility of operation, minimal degradation of existing air quality, attainment of economies of scale of pollution abatement, and retrofit of future best available technologies of pollution abatement equipment.

page 2. The DEIS does not discuss the effect of long-term operation of a network of ash ponds on ground water quality. Ash ponds would serve as sumps for both solid and liquid wastes. (An inadequate description of this problem is outlined on page 26 of the DEIS). It is also important to discuss the quantities of waste involved with an appropriate extrapolation for any additional units now planned or envisaged.

---

Exhibit 4

The operation of wet cross flow induced draft cooling towers needs to be discussed in greater detail. Employment of these devices should be compared to alternatives such as natural draft cooling towers. Mechanical or induced draft towers have a substantial potential for ground fog formation as well as sleet and ice formation during cold weather. Considerable attention must be given to the site selection as well as the local climate and flexibility of operation of the particular towers in question.

In addition to the potential for fogging and icing, mechanical draft cooling towers seem more prone to producing drift which may have an adverse environmental impact on the area immediately downwind from their site. The salinity of the drift may pose problems. Salinity is a function of the operational characteristics of the tower, the dissolved solids content of the cooling water, and the rate at which blowdown is bled from the cooling system. Little of the requisite information for calculating the impact of drift is available in the DEIS.

Mechanical draft cooling towers tend to be noisy in operation. Since there is no detailed description of these mechanical draft cooling towers in terms of the number of cells, rated horsepower of motor-driven fans, and plans for noise abatement (if any), it is difficult to calculate the impact of these devices on the adjacent population. We are informed of the environmental costs--in terms of unacceptable noise levels--of installing mechanical draft cooling cells to handle the cooling requirements of Indian Point Unit No. 2, a 873 megawatt generating station on the Hudson River.[3] The cooling requirements of a 700 megawatt coal-fired generating station in Southeast Montana are roughly half those of Indian Point Unit No. 2. Other parameters being equal, a reasonable assumption for cooling requirements for the proposed Colstrip Generating Station would require 19 mechanical draft cooling cells operating in the closed-cycle mode with each cell possessing an electric motor-driven fan rated at 200 hp., giving a total of 3,800 hp. The noise generated by these cooling towers is predicted to produce sound levels of 50 db. (A) at a distance of 3,500 feet. Consequently, an area of approximately 1.4 square miles will be in the unacceptable zone as defined by the Department of Housing and Urban Development.

Of this area, approximately 2 million square feet in the immediate vicinity of the cells will be in the "clearly unacceptable" classification with the remainder of the unacceptable area falling in the "normally unacceptable" classification. These particular acoustic levels are those which are emitted from the louvered face of the cells. The sound level on the cased face of the cell is expected to be from 5 db. to 10 db. lower, so the corresponding areas will experience lower noise levels. Therefore, the above hypothetical noise levels are conservatively high on the case-faced base side of the cooling cells.

3 The Final Environmental Statement on Indian Point Nuclear Generating Plant Unit No. 2 (Docket No. 50-247) prepared by the staff of the U.S. Atomic Energy Commission (page XI-64).

Exhibit 4

Attention should be given to noise levels from future installations at this site, as well as the one under consideration at the present time. A much more complete site description (with detailed maps of the facilities) is clearly indicated.

Pipeline and Water Supply

The DEIS describes the water supply and cooling system in only the sketchiest of terms despite the fact that this is a crucial feature of the generating station and one that will, in both the construction and operating phases, have a substantial impact on the environment. If the proposed generating station is but the first of a series of generating stations at or near this site, the cooling water supply system for the overall network of generating stations should be described at the outset of the first construction project. Information should be presented in the DEIS regarding the applicant's total water contracts for this region, future power needs, total fuel supply, and the like, since water in the area is a precious commodity and a limiting resource for industrial development.

Repetitive destructive impacts on the environment from the construction of a network of pipelines seems senseless. Yet, in failing to deal adequately with this subject at the outset, the decision-making bodies in the State of Montana may certify a future filled with applications of this sort. If, as discussed below, the initial pipeline is sufficient to serve a much larger generating complex, the DEIS has not candidly analysed the full environmental impact of the proposal. In either eventuality, the pipeline is a precedent-making feature of industrial development in the Colstrip area and needs to be examined with the greatest attention. Indeed, the plausible alternative of dry cooling towers should be probed in depth at this time.[4] No one should fail to recognize that the decision to certify the presently proposed cooling system on this plant may, by establishing a precedent, seal the fate of the Yellowstone River in perpetuity.

Inadequate or non-existent in the DEIS are discussions of studies (related to the impact on aquatic biota, migratory fish, primary producers and consumers, and fisheries) of the consequences of removing large quantities of cooling water from the Yellowstone River. Implicit in any such studies must be the view that, within the foreseeable future, a sizeable portion of that river could be diverted for industrial purposes. Thus, the aggregate impact including such phenomena as the impignment of fish on screens and entrainment of fishes in pumps and in industrial cooling systems should be considered at the outset of industrial development.

In particular, there should be no justification for approval of this diversion of cooling water on the basis that it constitutes a minor or negligible impact on the Yellowstone River Fishery if, in fact, it can be seen that future diversions will constitute a major adverse impact. There is no sound economic justification for permitting the aquatic biota of the river to subsidize the initial industrial development,

---

4 A 20 MW(e) air cooled electric generating station is operating in Gillette, Wyoming and a 330 MW(e) facility is planned for the same site--also to operate with dry towers.

Exhibit 4

whilst imposing the bulk of environmental costs on future generations of water consumers in the area, if it is perceived that approval of this initial usage in any way precipitates future industrial and commercial water demands.

There is reason to believe[5] that the proposed pipeline for this power plant will be very much larger than required by a 700 MW(e) coal-fired steam electric generating station. The DEIS itself is suspiciously vague in this regard. For example, page iv of the DEIS refers to the pipeline as "24" diameter (minimum) approximately 30 miles" and on page 2 of the DEIS the pipeline is referred to as " . . . a buried steel pipeline at least 24-inches in diameter." [emphasis supplied]. Such a discussion of one of the most important features of this project is ambiguous and unsatisfactory.

There is no mention in the DEIS of the pumps required to move the water from the Yellowstone River to the generating station at Colstrip. Aside from the impact of these devices on the aquatic biology (by impignment, entrainment and bottom scouring) their size gives a reasonably accurate gauge of the near term plans of the Montana Power Company. Of course, an essential feature in future plans of the utility is the diameter of the pipeline itself.

Though the DEIS may describe the pipe as equal to or greater than 24-inches in diameter, it seems that a permit application describing the intentions of the Montana Company is on file at the Rosebud County Courthouse in Forsyth, Montana. This application calls for a 60-inch pipeline.

A 24-inch pipeline operating at a flow rate of 5.664 feet per second will supply 7,926 gallons per minute, sufficient to handle the total consumptive use of water of the 700 MW(e) generating station described in the DEIS. Table 1 depicts the electric generating capacity of such a complex as a function of pipeline diameter when the water velocity is 5.664 fps.

---

5 c.f., the Billings Gazette series of articles on the Project commencing 29 November, 1972; also, repeated private communications from members of the Northern Plains Resource Council in Billings, Montana.

Exhibit 4

Table 1 [6]
(Water Velocity = 5.664 feet per second)

Pipe Diameter inches	Flow Rate cfs.	gpm.	acft/yr	Sustained Generation Capacity [7] MW(e)
24	17.7	7,926	12,800	700
36	39.8	17,830	29,000	1,575
48	70.7	31,700	51,000	2,800
60	110.3	49,540	80,000	4,350
66	133.7	59,940	97,000	5,300

We are further informed that the application for permit describing the intentions of the Montana Power Company describes the 60-inch pipeline as capable of delivering a flow of water of 250 cubic feet per second. Table 2 gives the sustained generation capacity of a power plant complex as a function of pipeline diameter at a flow rate of 12.85 fps., i.e., a rate of 250 cfs through a 60-inch diameter pipe.

Table 2 [6]
(Water Velocity = 12.85 feet per second)

Pipe Diameter inches	Flow Rate cfs.	gpm.	acft/yr	Sustained Generation Capacity [7] MW(e)
24	40.1	18,000	29,000	1,590
36	90.5	40,500	66,000	3,575
48	160	72,000	116,000	6,350
60	250	112,500	181,000	9,875
66	303	136,000	220,000	12,000

---

6 1 cubic foot per second (cfs) equals 448.83 gallons per minute (gpm) or approximately 725 acre feet per year (acft/yr).

7 At 100% load factor; these data are based on cooling water requirements of 25.2 cfs per 1,000 MW(e) generated.

Exhibit 4

It is pertinent that the North Central Power Study [8] refers to an aquaduct from the Yellowstone River to Colstrip, Montana. This is dexcribed as a 66-inch pipe with a capacity of 130 cfs. or an annual water delivery of 90,000 acrefeet. This proposed pipeline will be operating at a slightly lower rate of flow than that described in Table 1 above, and would be sufficient to handle the cooling requirements of a 5,150 MW(e) coal-fired steam electric generating complex. It should be noted that the Montana Power Company was an active participant in the preparation of the North Central Power Study.

With the above information in full view, it seems that the discussion on water supply (and indeed the entire DEIS) has been less than forthright. Whether or not this represents a failure of the utilities to disclose their intentions fully to state decision-makers is of little significance. The Environmental Defense Fund believes this failing can only be remedied by the issuance of a revised Draft Environmental Impact Statement which describes the proposed water supply system comprehensively and the attendant environmental consequences of such a supply. Without such a discussion, it is impossible to analyse the full environmental consequences of this proposal objectively.

Transmission Lines

The DEIS fails to examine the full impact of transmission lines, switching facilities, and the like, upon the environment. There is a clear need to supply quantitative information about number of acres impacted, the compromise of aesthetic values in pristine areas, the irreversible committment of private and public lands for industrial purposes, the adverse impacts of transmission facilities on wildlife, and the adverse impacts of transmission facilities on lands of an archaeological or historical value.

It is important to describe the degree to which the choice of any particular transmission corridor will delineate future routings of transmission lines for the utility in question (as well as other corporations which share interties and transmission facilities). If, as is indicated, this is but the first in a series of large coal-fired generating units in the area, there is an obvious need to enter into detailed open planning at the outset of the project. In particular, it is important to determine the activities of other utilities in the region. The past record of cooperation between the investor-owned utilities in the region, the Bureau of Reclamation, the cooperatively operated utilities and municipally owned systems has been a sorry one indeed. [9]

---

8 To North Central Power Study, Report of Phase I, Volumes I and II, October, 1971. Bureau of Reclamation, U.S. Department of the Interior, Billings, Montana, (Volume II, page I-34).

9 c.f. for example the Mid-Continent Area Power Pool Agreement before the Federal Power Commission. Docket No. E-7734.

Exhibit 4

For both environmental and economic reasons it is important to plan for and determine interties between the various utilities in the region, the Bureau of Reclamation facilities, and other agency facilities, in order to plan for system stability. This will avoid costly duplicative transmission facilities and generating units. At the very least, these objectives should be spelled out and the ability to comply with them assured before the granting of approval for construction of any further generating units or transmission facilities of the Montana Power Company.

page 4. Since the construction of a mine mouth coal-fired steam electric generating station is determined by these very economies of scale (e.g., transportation of fuel and ash disposal), that arise from proximity of the mining and combustion processes, there is no adequate argument for severing the environmental impact statement on mining from that which deals with the remainder of the operation. Indeed, there is every reason for uniting these impact statements in a revised draft form.

If the Montana State Department of Lands "will make intensive evaluations of the strip mining reclamation necessary for this facility" [emphasis supplied], there is no reason to approve construction or operation of this generating station until such time as the indicated studies are complete. If approval to construct is granted prior to complete stipulation and assurance of ability to comply with mining practices, the State of Montana will forfeit control of the operation and be faced with economic blackmail after the Montana Power Company and its partner have made a sizeable capital investment in the proposed facility.

The success of reclamation depends, of course, on a definition of terms. In areas such as Colstrip with low annual mean precipitation and wide annual variance of precipitation, the prospects for permanent reclamation seem poor (if the term means successful revegetation through the first drought cycle without irrigation or application of fertilizer). Thus "reclamation" in the West German, British, or Appalachian sense of the word has not been proven and does not seem favorably indicated in at least a portion of the Northern Plains States. Other aspects of reclamation (leveling of spoil banks, grading of high walls, and preventive measures to assure good local water quality) can and ought to be stipulated in approving the overall design and mining regimen of the proposed facility. Further, it is important to stipulate that the mining operations are not only in compliance with existing laws, but also with future State and Federal reclamation laws as a prerequisite to operation of the proposed facility.

The proposed 700 megawatt generating station will consume a little over three square miles of land during thirty years of strip mining. Additional envisioned stations will consume correspondingly more land. If this land is lost as a resource in perpetuity, it is important to assess the full environmental costs at the outset of operations. The land must not merely be allowed to be reassessed on the tax rolls at zero dollars per acre after mining has ceased (as has actually happened in Wyoming and elsewhere); indeed, full environmental and economic costs should be established at the outset for any damage that may occur in perpetuity.

Exhibit 4

Historical Values

If an area is to be irreversibly committed to the strip mining of coal it is important to assess the impact of the operation on historical and archaeological values. To this end, it is advisable to consult with state and national historical and archaeological societies to determine the nature and extent of any adverse impacts.

Recreation

The impact of this generating plant on tourism is not investigated at all. The impact of the proposed facility on wildlife and fisheries needs to be examined in greater detail. In particular, the migratory and feeding patterns of wildlife will be adversely affected by the physical obstacles imposed by the proposed facility, as well as by noise and increased human activity in the area. Perhaps most importantly, the Yellowstone River Fishery will be adversely affected by this and future operations scheduled for the same site. It is essential to establish liaison with State and Federal departments of fisheries and wildlife, as well as conservation, recreation, and sportsmen's organizations prior to the promulgation of the DEIS.

Meteorology

It is essential that meteorological factors which affect local air quality are determined in the planning stage. These should include local wind conditions, prevailing temperatures, saturation deficits, and the precise nature and extent of inversion conditions. Such knowledge is essential for the choice and design of cooling systems--in this instance the selection of forced-draft wet cooling towers seems to have been made on the basis of incomplete meteorological data.

Regional monitoring appears to have been performed for some, but not all of the expected pollutants. For the one pollutant which is most difficult to control, (oxides of nitrogen) no background monitoring has yet been performed. The draft environmental impact statement suffers from a lack of presentation of wind roses for pollutants. It is impossible to review and comment objectively on the quantative impacts of air pollution in the absence of such data. In the absence of any quantitative information pertaining to emissions, meterology, topography and proven methods of atmospheric modeling, it is a relatively simple matter to "readjust a few parameters" and find the unit in complete compliance. The complete array of data and methodology must be presented in the DEIS.

Exhibit 4

page 9 Probable Impact on the Environment

As referred to above, the data in Table 1 of the DEIS is exceedingly difficult to interpret without the appropriate wind roses. There is a clear need to define the diffusion model employed for calculations of the proposed plant's contribution of pollutants. If, as is intimated, a complex of coal-fired generating stations is to be built, this DEIS is the appropriate vehicle for describing the contribution of all the proposed plants.

page 12 Particulates

The DEIS suffers from being totally dependent on data supplied solely by the applicant. It is important to note that controlling the emission of particulate matter to the level of 266 lbs. per hour depends on operating the scrubbers at maximum collection efficiency, in order to remove 53,200 lbs. per hour of particulate matter from the flue gasses at full load. Even a slight loss in efficiency will lead to a drastic increase in emissions of particulate matter. Table 3 compares the efficiency of operation of these scrubbers and particulate emissions:

Table 3

Efficiency of Particulate Removal	Particulate Emissions (lbs. per hour)	Particulate Emissions (Tons per year)
99.5%	226	1,165
99.0%	532	2,330
98.0%	1,064	4,660
95.0%	2,660	11,650
90.0%	5,320	23,300

Sizeable losses of efficiency in such equipment are not uncommon and occur as a consequence of: (1) inadequate technical experience with the operation of very large electrical generating units; (2) poor operation and maintenance; (3) corrosion or deposit buildup in the scrubbers themselves; and (4), the general fatigue of units operating at the outmost limits of their efficiency.

Other data in the DEIS can be employed to calculate that this generating station may be operated at an 89% load factor, although such calculation is somewhat sketchy as it depends on the statement given on page 41 that "90 million tons [of coal] will be burned in 30 years . . . ." Thus the full load emissions given in Table 3 should be corrected by multiplying by a factor of 0.89 in order to obtain the expected average emissions of the plant. A load factor of 89% is not inconsistent with the mature outage rate of 4 or 5 percent on top of routing maintenance, though it may be slightly optimistic.[10]

---

10 See, for example, data supplied by the Edison Electric Institute's Equipment Unavailability Report 26-71.

Exhibit 4

page 13

It is inconsistent to compare the proposed coal-fired generating station with the Corette plant of the Montana Power Company, since the Corrette plant is presently operating under a different array of stipulations and does not comply with EPA regulations for new coal-fired steam electric generating units. The Corrette plant presently emits 426 lbs. per hour under full load, but, if built today would be permitted to emit no more than 175 lbs. per hour at full load. Present particulate emissions from the Corette plant are thus 244% of those permitted for new generating units.

Table 3 of the DEIS presents measurements of particulate matter (taken at what is evidently a single sampling site some nine miles east of Colstrip) for a six month period in mid 1972. As noted above, these and other data are impaired by the lack of discussion of regional meteorology. If, for example, inversion conditions are more frequent in the winter than during the summer, the statement that "(the winter will certainly bring reduced total suspended particulate values)" is questionable.

page 13

The discussion of dust is incomplete without a consideration of particulate matter which will be produced directly by the stripping of coal. Strip mining in a region does produce considerable quantities of dust and this source of particulate matter should be taken into consideration with the other sources described. This is yet another argument for uniting the present draft Environmental Impact Statement with the one proposed to deal with the strip mining aspects of the operation.

page 16

The computer dispersion model and the long-term concentration model should be described in the draft statement. The failure to provide these together with substantive meteorological data for the region is a serious shortcoming of the DEIS. A tremendous range of model results can result dependant upon : (1) the choice of the model; (2) the accuracy of easily calculated parameters--quantities of pollutants, stack gas velocity, and the like; (3) the discretionary choice of measurements and sites; and (4) the accuracy of meteorological phenomonon calculated for or observed at the Colstrip site. One of the most frequent shortcomings in power plant site selection results from the lack of attention that utility companies and regulatory bodies give to the meteorological characteristics of the site. This can occassion enormous expense when remedial action becomes necessary.

With regard to the discussion of particulates, sulphur oxides, and nitrogen oxides, it is important that the DEIS consider additional parameters. For example, it was stated on page 5 of the DEIS that the coal has an average composition of 8.5% ash and 0.77% sulphur. It is important to determine how and by whom this was measured, as well as to know how these parameters will change over the estimated lifetime of the power plant. How much variance is there in the sulphur and ash content of the coal? Will the proposed mining regimen dictate the initial combustion of low sulphur, low ash coal and in later years the combustion of coal containing higher quantities of ash and sulphur, or will the reverse be true? Regarding nitrogen oxides, what are the known operating characteristics of tangentially-fired pulverized coal furnaces of this design? Have nitrogen oxides been measured in the stack gasses in a unit of this design and if so, what are those measurements?

Exhibit 4

page 18 Analysis of mercury indicates that the plant will emit somewhere between a few pounds and an amount in excess of 2 tons of mercury per year. We believe that, if careful systematic analyses are performed, a more accurate estimation of the mercury emissions can be provided. In view of the quantities of such elements as mercury and fluorine found in western coal, it is most important to have objective analytical data concerning these and other constituents. There is reason to believe that there are substantial quantities of fluorine in the coal in question, and that the 12.5 ppm F upper limits determined by Truesdale Laboratories may represent a serious underestimate of actual fluorine concentration.

page 19 Radioactive Substances

The use of Curies per year for describing radium emissions is ambiguous: ^{226}Ra decomposes with a half-life of 1590 years to give ^{222}Rn which then decomposes with a half-life of 3.82 days to give ^{218}Po. ^{218}Po then decomposes with a half-life of 3.05 minutes to yield ^{214}Pb which decomposes with a half-life of 26.8 minutes to yield ^{214}Bi which can decompose through a number of mechanisms and intermediates to yield a single stable end-product, ^{206}Pb.

Just what is meant by "Ci/y" is therefore unclear, since this has the units of disintigrations per (unit time)^2. Total-body doses to an individual (in mrem/year) at the plant boundary might be a suitable substitution, together with a calculation of the man-rem dose to the population within 50 miles of the site as a percentage of the suggested guidelines of the AEC set forth in 10 CFR 20 (with proposed modifications).

From the data provided it can be calculated that 2.1-2.31 tons of uranium and 5.22-9.0 tons of thorium will be emitted per annum. Total body doses ensuing from these materials should be calculated as above for radium.

page 20 The DEIS fails to examine the synergistic effects of pollutants. The operation of any design of wet cooling towers will produce a very moist plume (visible at most times) which can be expected to mix with and greatly increase the humidity of the plume containing the stack gas pollutants. The DEIS should, for example, discuss the increased acidity of the "greater precipitation potential."

page 21 It is important to emphasize that the impairment of visibility by particulate matter is most heavily dependent on the quantity of micron and sub-micron particles injected into the atmosphere. This topic is particularly germane in an area such as Colstrip which presently boasts such pristine air quality that the entire region is collectively known as the "Big Sky" country. Other things being equal, the mass of

Exhibit 4

particles falls off as a function of the cube of the radius (e.g., as 4/3 pi r^3). Removal of 99.5% by weight of the particulate matter could, under the appropriate circumstances, effect the removal of only a tiny fraction of the micron and sub-micron sized particles. It is important to know the efficiency of the Venturi Scrubbers in the removal of such small particles. Thus, considerably more analysis is necessary before one can safely make the statement which appears on page 21 of the DEIS, that: "Particulates are considered the main culprit in visibility reduction and aesthetics, but their effect here will be minimized due to the low emission rates resulting from a 99.5% control efficiency."

The DEIS states that visibility reduction might be expected to " . . . be rare in the Colstrip region because of the relatively low humidity as compared with other areas of the country. It is well established that high humidity combined with sulphur oxide in the atmosphere contributes to visibility reduction."

At full load, the proposed generating station is expected to produce 6,646 gallons per minute (gpm) of water in evaporation and drift from the cooling towers, 500 gpm in evaporation and entrained water originating in the passage of the flue gasses through the scrubbers, and an unspecified amount of water vapor (dependent on the hydrogen and water content of the coal) from the combustion of the fuel. As noted above, the DEIS fails to discuss the mixing of the plumes from the cooling towers and the stack gasses. Hence, such statements as that quoted on page 21 of the DEIS are without substantiation. It should be noted that in other locations the mixing of these plumes is not uncommon.

It is reasonable to expect that a varying portion of the water vapor from the cooling towers will, in fact, continually mix with the stack gasses, while another varying portion may indeed by a "low level source" leading to fogging and ice formation during periods of cold weather. It seems that inadequate or no modeling has been performed to examine these problems. In addition to the missing information noted earlier in these comments, one must know the exit characteristics of the water vapor plume from the cooling towers.

page 22 If " . . . a visible plume will be evident from the stacks that will vary in size depending upon the temperature and humidity," why is no mention made of the visible plume that will be evident from the cooling towers? Why is there no discussion of the possibility of ice formation during cold weather? Why is no mention made of the potential hazards to travel as a consequence of ice and fog formation?

Effects on the Ecosystem

Discussion of effects on the ecosystem seems most inadequate. This is particularly so in view of the evidence that the proposed generating station may be only the first in a series of large steam electric generating stations at or near Colstrip. The effect of industrializing a rural agrarian region with the attraction of large

Exhibit 4

quantities of cheap electric power is of overwhelming importance to the survival of wildlife. It may be that "a quantitative estimate of these effects is impossible at this point in time, given our present understanding of the fate of pollutants in the ecosystem," but there is a growing body of substantive knowledge which allows us to make qualitative predictions. Instead of delving into this subject, the DEIS appears to succumb to helplessness, as if the fate of this region were completely in the hands of the Montana Power Company. The inadequacy of this portion of the Draft Environmental Impact Statement is sufficient in itself to compel the issuance of a Revised Draft Environmental Impact Statement before further action is taken.

page 23 Emission Control Guarantees

The DEIS reads: "The problem of plugging and fan imbalances from flyash and flyash and sulphur oxide combinations is recognized. The few recently-constructed power stations now equipped with scrubbers are experiencing these problems and investigating possible solutions." This portion of the Draft Statement would benefit by a discussion which names these stations and delineates the problems and solutions in detail. It seems that in any certification of these generating units and scrubbers, it should be stipulated that operation would not be permitted unless the efficiency of particulate and sulphur dioxide removal was at or above the guaranteed level on the emission control systems. The DEIS suffers generally from a lack of discussion of sources. A Revised Draft Environmental Impact Statement should incorporate detailed information on the emission control system, together with material germane to this subject (available, for example, from the U.S. Environmental Protection Agency.) Since the Montana Power Company budgets and spends little or no money on research in this area, their confidence " . . . that scrubber systems are inherently workable and that these problems can be met by design or process change" seems at best secondary to the confidence expressed by experienced operators of the equipment.

page 24 A number of these "Special Environmental Studies" need to be performed prior to certification of any aspect of the proposed project. Of paramount importance are: (1) the gathering of meteorological data; (2) the precise determination of the presence of trace elements in coal and their disposition through combustion; (3) additional air quality monitoring; and (4) broad ecological studies.

The most important aspect of the Participant's proposed environmental policy is full and open planning. If the Montana State Department of Health and Environmental Sciences has in any way been limited in the preparation of the DEIS by the failure of applicants to supply full and complete details on its proposed operation, then the proclamation of future behavoir by the applicant on pages 24-25 of the DEIS is of dubious merit. The DEIS sorely requires substantive documentation and detail. Much of this information can be supplied only by the applicant. If, in the future, the full details of operation, maintenance and monitoring are withheld from the public by the utilities responsible for enforcement, we are less than sanguine that these promises will be kept.

Exhibit 4

page 25 Again the discussion of dust suffers from a failure to mention particulate emissions (coal dust) from the actual mining of the coal. Potential for groundwater contamination by leaching of the ash should and could be studied prior to the commencement of mining and ash disposal.

page 26 The concentration of dissolved solids as well as slimicides and the like in the blowdown from the cooling water may present a groundwater contamination problem, and not merely "precipitate out into the pond." These materials could and should be easily quantified and described in the DEIS.

The disposal of sewage through dilution flows in Armell's Creek should be reevaluated with attention given to full compliance with the 1972 Federal Water Pollution Control Act.

page 28 We note with interest the statement that: " . . . the proposed Colstrip plant may be only the first of many industrial developments that could conceivably alter the land use of most of the Fort Union Region." This statement deserves elaboration, particularly in view of the indications that a number of additional electric power plants presently are being planned for this region.

page 29 Though it may be impossible to quantify the changes in the flora and fauna discussed in this section, we believe that it is possible to " . . . predict the major changes in such activities as sport fishing." Thus we take exception to the DEIS and further suggest that the Revised Draft Environmental Impact Statement attempt to make some qualitative predictions -- with the help of available sound ecological modeling--as to the major changes in composition of flora and fauna attendant to the various scales of industrial development which can be envisaged for the region.

page 30 Impact on the Human Environment

An increased tax base is one tangible benefit that can result from industrial and commercial development. Any discussion of impacts on the human environment should be accompanied by a detailed description of the expected tax revenues delineating the individuals, municipalities, and governments to whom those benefits will accrue. Will the costs occassioned by the proposed development be equitably defrayed by tax revenues? To what extent are "more and better educational facilities" required in this region? What "transportation systems" and "communication systems" -- besides the private automobile and the existing roads and media--are envisaged for this region?

The discussion of the impact on the human environment, the senses and the community on pp. 29-32 is interesting, although not particularly enlightening. For example on p. 30 of the DEIS we read:

> Traditionally, agrestic life styles have been slow paced and relatively simplistic, whereas existence

Exhibit 4

> in an industrial society is characterized by a hectic, rapid pace complicated by such necessities as the social graces and who gets a key to the washroom.

It is not clear that meaningful sociological expertise has been brought to bear on the problems discussed in these sections. The vitae of those individuals preparing the DEIS indicate training in engineering and the physical sciences--but not sociology. The lack of sound rural sociological analysis of the human environment is a serious shortcoming of the DEIS.[11]

With regard to other areas of the U.S. where one can " . . . perceive the effects of unplanned and poorly planned development in a rural-agrarian area" we believe a compelling example is the Southwest energy complex consisting of the Four Corners, Navajo, Huntington Canyon, Mojave, San Juan and Kaiparowitz Power Plants having a total planned capacity of 36,000 MW(e). If this proposal has even the faintest chance of being the first step in a parallel direction (i.e., Colstrip, Birney, and Gillette), it is obvious that very much more careful planning must be performed.

The entire section dealing with impact on the human environment fails to discuss any impacts on human health. This is a most serious ommission.

age 32 Any discussion of noise levels in the area should be included in a discussion of human health impacts and should include a detailed analysis of the noise produced by the proposed cooling system. It should be recognized at the outset that noise constitutes much more than an aesthetic problem--it is frequently a serious human health insult. Due attention must be given to compliance with The Noise Control Act of 1972, as well as the Occupational Health and Safety Act of 1970.

age 33 The list of adverse environmental impacts which cannot be avoided seems incomplete. It should certainly include the impact on wildlife and fisheries, the impact on groundwater quality, as well as the quality of the Yellowstone River, the impact on regional climate, the local potential for fogging and icing, human health impacts in the region including noise, and a discussion of the various impacts which can be expected in the aftermath of stripmining (only briefly alluded to on page 41 of the Draft Environmental Impact Statement).

---

11. A similar comment applies to the lack of economic analysis discussed below.

Exhibit 4

 Alternatives to the Proposed Action

A. Not to Construct

The DEIS contains no discussion of the need for this power within the Montana Power Company's own service territory. The bulk of this new power may be exported to the Montana Power Company's partner in this venture, the Puget Sound Power and Light Company. The lack of any discussion of the advisability of degrading the environment of Montana to satiate the electric demands of the Pacific Northwest is a serious flaw in the DEIS and presents another strong motive for issuing a Revised Draft Environmental Impact Statement prior to the initiation of any further action in regard to this proposal.

B. Other Fossil Fuels: Oil and Gas

In view of the relatively poor apparent heat rate of the proposed plant (the calculated efficiency is 35.2%),[12] the alternative of reserving this particular coal deposit for future exploitation (either combustion with improved technology or coal gasification) should be explored.

C. Nuclear Fission Plants

The argument that " . . . energy required to process this fuel [enrichment in ^{235}U] for power plant use likely contributes, at another location, environmental degradation." is sound. However, the statement that "fission plants require vast quantities of cooling water . . ." is unnecessarily vague and implies that the proposed plant has, in comparison, only a modest requirement for the consumptive use of water. In fact, the proposed plant will consume roughly 70% of the water required by a 700 megawatt nuclear fission plant of recent design operating at 33% efficiency. It should be noted that Philadelphia Electric Company and other utilities have ordered high-temperature gas-cooled nuclear reactors which will operate at roughly 41% efficiency. These latter devices will consume about the same amount of water per kilowatt hour produced as the proposed 700 megawatt coal-fired installation in Colstrip.

D. Solar Energy

Although the direct conversion of solar energy into useable electric power is not yet technically or economically feasible on a wide scale, the conversion of solar energy into heat (e.g., for space or hot water heating) is now a workable and

---

12 This figure should be reduced to compensate for pumping requirements, cooling tower fan requirements and pollution abatement equipment requirements--all presently unknown. Transmission losses are not discussed, either.

Exhibit 4

marketable technology in a number of areas in the country. A considerable body of knowledge on this subject now exists and a number of groups (e.g., the Environmental Quality Laboratory at the California Institute of Technology) are seeking the speedy implementation of this technology in residential, commercial and industrial markets. Insofar as the electric power production of the Montana Power Company is converted into heat at the site of demand for purposes of space and water heating, it is germane to investigate the suitability of solar energy as a substitute.

age 37 Utility promotional efforts and discount rates for electric heating should be carefully reviewed and, if necessary, abated. It seems foolish to increase the rate of growth of electrical demand unnecessarily by promotional activities which may not be in the best interests of the residents of the State of Montana. Peak demand charges should be instituted in order to internalize the external environmental costs of both the present demand and the growth of that demand.

There can be no question that a great environmental blessing to the Northern Plains States and especially Montana and Wyoming would be the lessening in the rate of growth of demand for electricity in the nation. In view of the plans of many energy companies and utilities, any reduction in the rate of exploitation of Montana's resources would bring benefits to the people of Montana in terms of human health, aesthetics, a broader brighter outlook for the tourist industry, and a reduced demand upon the state's free flowing rivers and streams.

Insofar as charity begins at home, the State of Montana must address the problem of demand for electricity within its own borders. This should be done with a view towards increasing the efficiency of use of electric power as well as insuring that the large users--those who presently pay the lowest rate per unit energy consumed--pay their full fair share of the environmental costs occasioned by the production and delivery of electric power. If Montana chooses to export its coal resources in the form of electricity, then everything within its power must be done to ensure that the full environmental costs of producing the power in Montana are assessed upon the distant consumer.

If a serious effort is to be made in controlling the demand for electric power in the State of Montana, it must be recognized immediately that a large portion of the financial returns to electric utilities accrue in proportion to their rate of growth. In general, the most rapidly growing electric utilities have the highest rate of return. This is the consequence of the reward system imposed by regulatory bodies. It is no coincidence that the Montana Power Company has enjoyed the highest rate of return of any electric utility in the country for several years during the past decade. It has consistently been one of the top five utilities in rate of return in the nation. If we are to cope with the demand side of the problem, every effort must be made to re-examine the way in which carrots and sticks are apprortioned to the electric utilities industry. It is also germane to note that Montana Power just received a substantial rate

Exhibit 4

increase from the state Public Utility Commission. We should not be complacent about the environmental consequences of such a rate increase--traditionally, high profitability, a strong position in the capital market, and recent substantial rate increases are intimately coupled with very high rates of utility growth. This, of course, leads directly to constructing the proposed steam electric generating station in Colstrip, Montana.

The failure to discuss any economic data or to examine the demand for power in Montana is one of the most glaring omissions of the DEIS. At the very least, the Montana Environmental Policy Act is an "open planning" statute. In the absence of hard economic ecological and engineering data, vague qualitative statements pertaining to benefits and costs fall into the realm of conjecture, not open planning.

CONCLUSION

In view of the paucity of data provided and the indications that one major aspect of the project--the 30-mile pipeline from the Yellowstone River to Colstrip--may be scaled to handle a very much larger complex of coal-fired steam electric generating stations, the Environmental Defense Fund urges the promulgation of a Revised Draft Environmental Impact Statement which will be both substantive and candid in dealing with the proposed power plant complex.

Dear Sirs:

Since I live on a ranch in the Colstrip area, I am extremely concerned by the implications of the generation plants that are now under construction at Colstrip.

The following questions and comments are in response to the Environmental Impact Statement on the electrical generating plants at Colstrip.

On page 1, paragraph 1, there is an error stating that the generating station is "proposed" when in reality, the plant(s) have been under construction for some time.

In paragraph 2, I want to stress the importance of this application, since its approval, or disapproval, will have far-reaching effects on future plants. The decision will be much more important as a precident than merely answering the question as to whether or not this facility is to be completed, and operated. There will be a further precident made as to whether the state should accept applications for construction long after the actual construction has been underway when considering future plants of this kind.

On page 2, paragraph 1, I wonder if consideration is being given to the deleterious effect of bottom, and percipitated ash on groundwater.

Concerning "Pipeline and Water Supply, on page 2, the companies are planning, and currently surveyingfor, a 60-inch water pipeline from the Yellowstone River, and are apparently planning their pipeline to supply subsequent plants at Colstrip in addition to the two now under construction. The on-going construction, and the 60-inch line that is planned, appear to be based on the assumption that not only is the present application going to be approved, but that future applications for construction will be summarily approved, as well.

In the section on Transmission Lines there is a further indication that the companies believe that the application will be routinely approved since they have already begun construction of one of the power lines.

Section 4 illustrates the importance of this application relative to subsequent plants.

In section 5 the word "proposed" again bothers me since construction has been underway for some time in what appears to me to be not only a violation of

Exhibit 4

the law, but a direct insult to your department, and the people of Montana.

In section 5, B, I wonder what the consequences, and the nature of the action would be if the emission control system will not perform as "guaranteed". Can, and will your agency shut the plant down if it is constructed, but fails to operate as "guaranteed??

In Chapter II, Section C, Land Use, the minimization of the lumber industry is done by comparison to the western part of Montana. I feel that the lumber industry is very important to Rosebud County. The figure of 11,000,000 bd. ft. sticks in my mind as being the annual county-wide production in recent years. Due to the economic importance of timber on the Northern Cheyenne Reservation, and the Custer National Forest, and the susceptability of ponderosa pine to sulfur dioxide, I believe the economic impact of the lumber industry should be stressed, rather than dismissed as being unimportant.

In Chapter III, Section A, 1, the three questions are essentially unanswered and this is the crux of the emmission problem. The application should not be approved until, and unless the answers to these very important questions are definately resolved, and are completely and unequivocally acceptable to the state, and those of us who live under the shadow of the stacks. There is little comfort for me in the statement, "Diffusion modeling indicates that only in rare cases will either state or federal ambient air standards be approached or exceded. " That "rare case", or the cumulative effect, might be all it takes to kill alfalfa, thereby destroying the hay base on many ranches in this area, precluding their continuation as viable economic units.

Billings is with in 100 air miles of Colstrip, and the additive effects of that city's refineries, and the Corette plant should be considered. The bentonite plant at Vananda, and the tepee burners at Lame Deer, and Ashland, as well as open burning dumps in many towns (including Colstrip) should also be considered as contributing factors to degraded air quality.

There is a serious error on page 13 relative to the sampling site nine miles east of Colstrip, and to a lessor degree other sampling sites as well. The sites are nearly all along dusty county roads, and the site nine miles east of Colstrip is in a ranch yard where many vehicles, and haying equipment passed close by each day during the sampling period. Vehicle exhausts, and the presence of a trash-burning barrel in close proximity to the sampling equipment preclude the assembling of any meaningful data.

No mention of the doubling effect of sulfur dioxide, and particulate matter in combination, and their effect on respiratory tract and eye irritations was made.

Under paragraph 5, surely more tests should be run and the effects of these trace elements should be understood before construction is allowed to continue. There are many more trace elements that should be investigated than the few mentioned. There is evidence that selenium is naturally in such relatively high concentrations that it might already be a limiting factor in livestock production in this area. "Testing for radiation will be conducted if and when the plant is allowed begins operations.", sounds like thinking about closing the barn door after the horse is gone.

Exhibit 4

No mention is made that the microparticulate matter is the size that will escape into the atmosphere. This is the hardest to capture, and is the most damaging size of the particulate matter from a health standpoint.

On page 24, the monitoring of air quality by Montana Power Co. is rather like running a fishing contest by the honor system. The guy who stretches the truth the furtherest gets the prize.

Continuing on page 24, and 25, I take ~~a~~ with a grain of salt all of the high sounding things the MPC says it will do. Number 4 is especially suspect since Company personnel have already told a group of area residents that the Company plans to build 7 plants at Colstrip with a generation capacity of 10,000 megawats. The cavalier attitude exhibited by constructing without a permit is hardly consistant with the pious sounding number 8, unless they are acknowledging that your department has already capitulated to their wishes, and that your approval is assumed to be automatic. Perhaps they meant that all local, state, and federal agencies and groups responsible for the protection of our environment should work harmoniously with the Montana Power Company and Puget Sound Power and Light Company to make the Colstrip project an asset in the companies' ledgers.

On page 31 you state that "...the basic economic pitfalls in an exploitive industry cannot be avoided." This is erroneous. The pitfalls in this instance can be avoided by disapproving the application for permit.

On page 32 Section 6, I would add a ~~sixth~~ fifth area that is already suffering from the impact of the increase in population, and this is the school. Perhaps this was included in the Economic and social parameters, however.

In rereading this letter I find that it smacks of insincerety and facetiousness, but rather than rewriting it to remove the offensive portions , let me say that I sincerely velieve that you should not approve the construction of these plants. Perhaps I feel this way because my ranch, and way of life are threatened. Perhaps I am selfish in wanting the world to pass me by. But I think that if these plants are completed, and they and other plants like them go into operation, all of us in Montana are going to look some day at a scarred landscape under a filthy sky, cut by dry river beds, populated by a callous, socially chaotic population and we will say what fools we were for not stopping this exploitation when we had the chance. I believe you said it all on page iii, in the Foreward, when you said, "The long-term adverse effects may well outweigh the short term gains. I urge you to disapprove the application.

Sincerely yours,

Wallace D. McRae

Director Air Quality Bureau
State Department of Health & Environmental Sciences

Dear Sir

As a full time commercial pilot I have been aware of and indirectly enrolled in the Colstrip and Decker mining projects.

I flew the railroad people over the Area on their initial sight seeing trips. I have flown numerous aerial surveys over the area for Private Citizens, mining and State officials.

In registering my strongest objections to the Colstrip project, I would like to point out the existance of a persistant inversion layer over this entire area during many days of the winter months. In fact one existed for several days only last week. This condition would trap the pollutants close to the surface and the Yellowstone Valley will become one vast Chimney

Mr. Benjamin F. Wake, Administrator
Department of Health and Environmental Sciences
Cogswell Building
Helena, Montana 59601

Dear Ben:

I want to register my opposition to the proposed mine-mouth generator at Colstrip. I have read the Environmental Impact Statement prepared by the Department of Health and Environmental Sciences, and this seems to indicate that air quality standards will be met by the proposed plant. However, of an equally serious nature is the un-regulated impact on river water, soil usefulness after being stripped, and the unstable tax base that will result from the proposed plant.

I feel that there is more to consider here than merely the emission data. The long-range effects of this proposal should far outweigh the immediate short-term benefits when considering whether or not to allow this plant to become a reality. The State Department of Health is responsible first to the people of Montana, and the benefits to be gained by Montanans by this proposal are negligible. We will contribute the coal, for which we can expect to receive at this time, only minimum compensation. In return for this we will sacrifice much of our land and the life style of many of our people. We will realize a drastic change in land use which has many unknown ramifications. We will provide the use of an undetermined quanity of water. We will live with the emission of gasses and trace elements into an environment which is relatively pure, with no data to suggest what the effects on the eco-system will be.

If it is determined that this proposal is to proceed, some method must be devised by which the recipients of this power help to bear the burden of its cost. If Montana must, by the unique composition of its coal, contribute so heavily to the nation's energy needs, it should be adequately compensated.

Instead of gearing ourselves to the depletion of our coal for an impending "crisis" which will not be solved by this depletion, we would be wiser to direct our efforts in the area of investigating thoroughly some of the proposed alternatives mentioned in the Impact Study, like

Exhibit 4

ginning the painful process of grinding down our efforts at conspicuous consumption, and by making an effort to conserve what we have--not to deplete it.

I certainly feel that there is little to be gained by Montana by proceeding with the construction of this plant.

Sincerely,

Jean M. Bowman

Dear Sirs:

My interest in the proposed Montana Power Company's generating plant at Col trip is one of a personal matter but more important from a professional standpoint. I am a Biologist whose knowledge of the detrimental effects that a company such as Montana Power can have on the environment extends further than the average concerned citizen.

Recently, under the helpful guidance of Lee Denson, Environmental Specialist for the Bureau of Reclamation and former Assistant to the Chief of the Endangered Species Program in Washington, D.C., I have been working on the critical situation that presently faces the Paddlefish status. I am now in the final stages of completing this study and hope to have it ready to send back to the Department of Endangered Species by the end of this week. They have already reviewed the study and had asked me to make a few corrections and send it back to the department.

You may be wondering how Montana Power will have any affect on the Paddlefish. Let me briefly explain. The proposed evaporators will require a certain amount of water from the Yellowstone River. The Paddlefish, of which there are two species, North American and China, are representatives of an ancient and primitive group of which very little is known. Spawning has only been observed once, literature is either outdated or scarce and they are isolated by the various dams on the Missouri River-Mississippi River Systems. Their status is UNKNOWN but yet is classified as a game fish in most states including Montana. Successful spawning has been determined to rely very heavy on rising, warm water levels and is the only initiator of the spawning migration process. Another words low water levels, decreased water flow and cold water inhibit successful spawning.

If more information is needed as to data, literature cited etc., I will be glad to forward as many copies as necessary in order to help in considering this one important species. I have spent more than nine months trying to compile enough information that would warrent placing this fish on the Endangered Species list as Status Unknown.

Sincerely,

Stephen C. Linder

Air Quality Bureau
State Department of Health
Cogswell Building
Helena, Montana 59601

Dear Sirs:

It is with increasing frustration that I view the continuous degradation of the quality of air in Montana particularly in Billings where the addition of the new Montana Power plant has appreciably added to the pall of smog during the past few years. I am an allergist and see many patients with severe asthma all of whom are noticeably worse during inversions. With the advent of yet another monster power plant in Eastern Montana, this can only get worse increasing the already serious problems in asthmatics, chronic bronchitics and patients with emphysema not to mention the increased problems that patients with hay fever, perennial allergic rhinitis and chronic sinusitis face with these pollutants.

I, therefore, protest the further degradation of our air in Montana through callous emissions from the huge power plants contemplated by Montana Power for the mindless increasing consumption of power in this country. In my opinion, if people want power, they should be made to pay for it at the price necessary to assure that its production will cause a minimum of pollution.

Sincerely yours,

L. Bruce Anderson, Jr., M. D.

Dept. of Health and Environmental Sciences
Cogswell Building
Helena, Montana

Members of the Air Quality Board:

Five years ago when the first news stories began to appear about the resurgence of the use of coal in Montana, I began to study strip mining and its impact on land and people. It was at that time that I became aware of a 1965 study on Appalachia by the U. S. Dept. of the Interior, and a corresponding publication on Surface Mining. Everything I read then spelled "bad news", and everything that has transpired since spells more "bad news".

At first I was concerned chiefly about reclamation of land after the mining. One needed only to be aware of what had happened, and is yet happening, in other parts of the U. S., to know that the similar destruction of productive land in Montana was unthinkable.

However, other factors even more unthinkable are the ultimate pollution to our air and water. Montana cannot be anything But the loser under present circumstances.

I hope that hundreds of letters reach your office. However, after investigation, and now knowing what you know about the grim possibilites for our environment, it would be your solemn responsibility as a duly constituted body concerned with the welfare of the citizens of this state, to take action regardless of whether or not you receive one single letter from any citizen.

I am enclosing a copy of a speech I have given recently to various organizations, and am also enclosing copies of statements I made at hearings during the Constitutional Convention, and on the floor of Convention Hall a few months ago in Helena.

If these statements were valid then, they are more so now. In my files are dozens of letters from Montanans who pleaded for a strong environmental plank. I would be glad to forward copies of them if you so wish. It is interesting to note that some of the things I fought very hard for are now being recommended by the Environmental Quality Council.

Since then, many more individuals have become aware of the threat to our environment, more groups have begun to organize to

COMMENTS ON COALSTRIP POWER PLANT IMPACT STATEMENT

There appear to be a number of serious inadequacies in the draft statement. The meteorological conditions which were used for the calculation of the 3-hour and 24-hour averages were not stated. The 1-hour average appears to be a fumigation condition which would be expected to produce concentrations of about the reported level. The 3-hour and 24-hour averages appear to have been drawn from 1-hour averages through division by factors of 3 and 24 respectively. Such factors would be appropriate for extending the 1-hour averages to the longer periods for fumigation conditions. However, it is likely that the fumigation condition does not produce the highest levels for these longer periods. The experience of the TVA authorities has shown that the maximum longer term concentrations are usually associated with limited mixing conditions and that the maximum 24-hour average may exceed 23% of the maximum 1-hour average.[1] Further, for a plant with this stack height they expect the maximum concentrations (1 hour) for fumigation and limited mixing to be about the same, thus the 24-hour levels would be expected to be about 0.10 ppm under the assumption that the fumigation conditions are representative of actual values.[2]

Second, high terrain is mentioned, but no topographic map is presented. This does not allow the reader to estimate what concentrations may occur when the plume is trapped in a stable layer which interacts with plume-height terrain. The 4400-foot terrain to the south would be at plume height. Under very stable conditions with low wind speeds sulfur dioxide concentrations of 0.7 ppm (1-hour average) would be expected. This illustrates the importance of terrain effects.

Exhibit 4

The levels of flourides reported in the coal are very low. For example, the lowest levels reported are about 40 ppm or ten times the level reported here.[3] Typical levels for coal average 130 ppm.[4] A report of an anomalously low value, such as this one, should be accompanied by some description of the sample preparation and probably an analysis by another laboratory. This is particularly important for flourides, because the data suggest that flourides tend not to be captured in [illegible] and may be easily lost during sample preparation. In this aspect flourides are very similar to mercury and it appears that Truesdale Lab reported low values in that case also. If the flourides actually averaged 130 ppm in the coal, the emissions would be as much as 2300 pounds per day.

Another inadequacy is the lack of data on other trace elements such as selenium, phosphorous and arsenic, all of which are similar to mercury and flourides in that they are more likely to escape particulate collection than other trace elements.[5]

The mercury emissions should also be discussed in terms of their effects on the aquatic environment. It appears that a single ton of mercury can pollute a stream flow of about 4 million acre feet. A level of .17 ppb in water appears to be capable of producing levels in the flesh of fish of .5 ppm.[6] This latter figure is above acceptable levels for human consumption on a regular basis.

Furthermore, emission of 5.5 pounds of mercury per day would be slightly above the emission levels permitted for chlor alkali plants. It is true that scrubbers may be able to collect some of the mercury, although it is clear that other particulate collection devices are

Exhibit 4

rather ineffective and poor collection efficienty (5% or less) should be assumed until higher ones have been demonstrated.

The adequacy of the secondary standards is subject to considerable question. For example, the secondary particulate standard of 60 ug/m^3 would be expected to permit average visible ranges of no more than 12.5 miles. Thus, at least to the extent that people value vistas of objects more than 13 miles distant, the standards do not protect against all adverse effects. It was considerations similar to this one which led New Mexico to ask that the non-degradation decision of the district court be upheld. Furthermore, the criteria documents point to synergistic effects of sulfur oxides and oxides of nitrogen on plants at levels below the secondary standards.[7] These levels could occur near the coalstrip plant.

Another difficulty with the statement is that the test method used to determine the particulate collection efficiency is not stated. I suspect that the ASME method is used, in which case the actual particulate emission may be understated by a factor of three or more.[8]

The last inadequacy relates to the discussion of visibility reductions. The conclusion does not seem to be adequately founded, although the paraseology is sufficiently vague to preclude a precise understanding of the conclusion. Small sources of particulates such as wood waste burners, gypsum plants and perlite mills produce considerable visibility degradation. Compared to these, the plant will be a large source, and, furthermore, the particulates which escape the scrubbers will be of a very small size and consequently will have a much greater impact on visibility per unit mass. These questions

Exhibit 4

need not be left in these vague terms. Plume concentrations of fly ash and particulate sulfate may be estimated so that a picture of the plume's effect on visibility under different meteorologic conditions can be presented. Such calculations should be for plume centerline concentrations rather than ground level values.

One last alternative should be mentioned: that of burning gasified coal. The emissions from the plant and the associated gasification facility would probably be low enough to meet non-degradation requirements.

There is perhaps one problem with the overall construction of the document. The only calculations presented are described as conservative, and in my opinion underestimate the probable impact. Furthermore, the impact is described as impossible to predict quantitatively. While there is an element of truth in this statement, I believe our present knowledge could be used to make "current best estimate" predictions which would be useful. Visibility restrictions associated with the plume would be a natural candidate for such predictions as would be plume impingement on high terrain.

DEPARTMENT OF FISH AND GAME

Helena, Montana 59601
November 17, 1972

Dr. John Anderson, Director
Department of Health and Environmental Sciences
Helena, Montana 59601

Dear Dr. Anderson:

As requested, we have reviewed your draft statement regarding the environmental impact of the proposed Montana Power Company electrical generating plant at Colstrip, Montana. We will attempt to categorize our comments on the report for easier reference. Before doing so, however, two general comments are in order. First, on practically every page of the statement the lack of information on effects of this development, the mining of coal, the power plant itself, reclamation, power lines and water needs appears obvious. Nevertheless, the development is continuing without regard for these question marks. Secondly, we believe a comparison is in order to clearly identify those individuals and natural systems of Montana that must absorb the adverse effects of this development for comparison with the benefits claimed, along with identification of where and to whom those power production benefits will accrue.

In regard to the "Description of Proposed Action" segment of the report, we have the following questions and comments:

This section discusses mine-mouth plants in Montana and states that in the past, power plants were generally located near load centers and the coal imported over long distances. The reasons for locating the plants in Montana is not specifically discussed. The report does state, "these mine-mouth plants are favored by environmental parameters, at least from the owner's standpoint." This statement definitely needs explanation as to what these environmental parameters specifically are. It is inconceivable that we can afford to sacrifice Montana's quality environment for the benefit of urban areas in the midwest and west coast areas. It would seem appropriate that those areas benefitting from cheap electrical energy should be made aware of the total cost of that energy by enduring the environmental degradation that attends its production.

The discussion on pipe line and water supply in this section fails to adequately discuss the effects of the pipe line on the terrain over which it is to be constructed, on the river where some type of diversion structure must be located, and on the aquatic ecosystem downstream from the diversion, particularly during times of low flows in the Yellowstone. Absolutely no data other than the quantity of the diversion is presented on this topic. Also notable by its absence is the discussion regarding the alternative of dry draft cooling towers.

Exhibit 4

The transmission lines discussion fails to adequately discuss the environmental effects of those structures, and again omits discussion of alternative power transmission techniques. It is also noted that the transmission line discussion terminates north of Billings, even though the purpose of the project is to produce power for consumption in the Puget Sound marketing area.

In regard to the "Probable Impact on the Environment" section, we have the following comments:

In discussing the impact of the various emissions - SO_2, NO_x, trace elements, mercury, fluorides and other radio active elements - the words "not known," "unknown," "very little is known," "no background information" and "results are preliminary" appear quite often, and emphasize the fact that this entire development, like the reclamation attempts, is putting the cart before the horse. A more logical approach would be to determine these effects elsewhere prior to development in Montana. This statement merely discusses the types of contaminants anticipated from the plant and emphasizes our lack of knowledge regarding their impact. Once again the discussion does not place the proposed plant in the perspective of total Fort Union coal region development.

As with the previous section, the effects of water and heat emissions from the power plant and the effects on visibility and aesthetics merely stress the lack of knowledge and emphasize the need to answer these questions prior to development.

Within this section background levels of sulphur dioxides are discussed. It is noted in the report that they appear to be higher than those suggested by the Environmental Protection Agency.

In noting the location of the sampling stations, it appears possible the open fires occurring for some time at the Peabody Mine may be influencing the data. Has this possibility been investigated?

In the discussion within this section of the effects on the ecosystem, we note the word "natural" which is used in reference to "an ecosystem containing species that have adapted to that particular environment and exist there because of that environment, not in spite of it." The terminology "natural ecosystem" needs clarification. Ecosystems that are immune from the impact of man are sometimes thought of as natural ecosystems, and they probably do not exist anywhere on this earth, with the possible and still questionable exception of the north and south poles and some uninhabited regions. Man's activities, in fact his mere presence, institute changes in the ecosystem. The ecosystem at and around Colstrip is obviously not without man's influence.

Exhibit 4

The white man has been there for the past hundred years, and prior to that the Indian affected the system. Plants and animals now present in that area are adapted to that ecosystem, their presence and abundance having evolved with man's activities - in this case, primarily agricultural land use dependent upon cattle and/or sheep grazing. With this in mind one can only marvel at the complexity of the ecosystem at Colstrip. For the present at least, any statements regarding the effects on the system are merely conjecture.

Again the wording of this section includes "impossible to predict," "maybe," etc., and merely emphasizes our lack of knowledge.

Within this section is also contained a discussion of special environmental studies. Once again we are conducting studies after construction decisions and plant sitings have been decided. To adequately study the impact of this kind of development, investigations should be begun many years prior to development. Once again we were forced to travel the same road as we have traveled on so many other environmental problems. Another example of this was our involvement with sagebrush eradication in this state. We lost in excess of 300,000 acres of sagebrush wildlife habitat in Montana before any studies were initiated to determine the effects of such eradication. Once again we are involved in what could simply be monitoring of a bad situation.

On the topic of the listing of special studies, it is impossible to evaluate their worth without reviewing the study outlines and obtaining some indication of the commitment of resources to these studies. Study titles tell us very little, if anything at all. We would appreciate the above information to assist us in our continuing evaluation.

We also noted with interest the participant's environmental policy statement which was printed in this section presently being discussed. Item No. 8 of that policy states, "work harmoniously with all local, state and federal agencies and groups responsible for the protection of our environment." Policy statements mean little unless they are backed by a commitment that is real.

An example of the company's intention, I believe, can be derived from an effort made by this Department in 1969 to initiate a study that would have produced the background information so obvious now by its absence. At that time Western Energy, the wholely owned subsidiary of the Montana Power, declined to enter into a cooperative study with this Department that would have cost them less than $1,000 per year. This fact should be considered when statements of policy are being evaluated. Three years of background data would have eliminated many of the unknowns so evident in this entire statement.

Exhibit 4

Again within this section in the discussion of ash and water discharge to the land, we note the words, "appear to be," "maybe," and "may result." On page 28 the statement is made, "without an expression of concern from the persons interested in maintaining some of the present land use in eastern Montana, the proposed Colstrip plant may be only the first of many industrial developments that could conceivably alter the land use of most of the Fort Union region." It appears to us that the "expression of concern" has in fact occurred, and is overwhelming. The question is, will this concern be reflected when the time comes to consider permits authorizing construction of projects causing the concern.

When discussing the impact on flora and fauna within this section, it is stated that the emissions from the generating facility will put a stress on some plants which may kill them or reduce their ability to compete with other species. Once again it is obvious we are proceeding with both facility construction and reclamation research without adequate knowledge regarding the plant species with which we are working. It is conceivable that reclamation is proceeding with plants sensitive to sulphur oxides and doomed to failure for that reason. This is just another example of the paucity of information available for discussing a problem of this magnitude.

In the discussion of the impact on the human environment, there are several items we would like to see discussed in greater detail. One is the value of undegraded natural environments as they affect the wellbeing of people, and the other is the impact an expanding human population, and in turn an expanding hunter population will have on already strained landowner-sportsmen relationships.

In regard to the "Adverse Environmental Effect Which Cannot be Avoided Should the Proposed be Implemented," we have the following comments and suggestions:

Under Item No. 2 of your list, we believe it should be acknowledged that the consumption of 4.2×10^9 gallons of water can be avoided. The installation of dry draft cooling towers would certainly reduce this consumption and would most likely be in the best interest of all other Montana water users, including those persons interested in maintaining healthy aquatic ecosystems. We also believe this list should be expanded to include: No. 9 - Under present reclamation procedures, decreased wildlife habitat and populations. No. 10 - Decrease in recreational opportunities provided by wildlife and undeveloped land. No. 11 - Reduction in what Montana is famous for - notably open space, a modest human population and an excellent fish and wildlife resource.

In regard to the section entitled "Alternatives to the Proposed Action," the report reiterates our lack of knowledge concerning other energy sources and our unwillingness to force serious consideration of alternatives - not only to

Exhibit 4

the development itself, but also to features of the development. An example of this is our unwillingness to discuss dry draft cooling towers versus wet cooling and other specific water-related project features such as offstream storage of water near the plant site to prevent depletion of the Yellowstone River during periods of low flow. Under any circumstance, the 8,000 gallon per minute diversion of water must be considered in the perspective of the ultimate projected development of the Fort Union coal field and not as if it were the only generating plant to be constructed. We all know this is only the first.

In closing, we certainly thank you for the opportunity to comment, and we hope our comments will lead to a more realistic appraisal of the impact of the power plants in question. You can be assured the Montana Fish and Game Department will do everything in its power to assist your Department in making these impact assessments.

Incidentally, at the most recent Fish and Game Commission meeting our Commission instructed us to immediately increase our effort on the coal fields, and as a result we are assigning an additional man to the Decker-Birney-Colstrip region so that our ability to provide information in this area will be improved shortly.

Sincerely,

Don L. Brown

Dear Mr. Holtz:

Re: Environmental Impact Statement on the Colstrip, Montana Power Company Plant

Enclosed are our comments on the Draft Environmental Statement. We appreciate the opportunity to review and comment on this. We also compliment the Department for an excellent overall Draft Statement.

I also enclose two documents as relevant to the case at hand. One is on alternatives in energy; I distributed it originally to the League of Women Voters' State Convention, Great Falls, May 1972. The second is entitled "Wanted: A Better Approach to Energy Planning." It is a critique of the North Central Power Study and recommendations for future planning, by ROMCOE. We feel that the Colstrip plant is deficient in the planning methodologies which we advocate.

Sincerely yours,

ROCKY MOUNTAIN CENTER ON ENVIRONMENT

Comments on
Montana Department of Health and Environmental Sciences
Draft Environmental Impact Statement on the
Proposed Montana Power Company
Electrical Generating Plant at Colstrip, Montana.

I. General Comments

The impact statement is unusual in that it seriously addresses the long-term implications of such a development, and in its conclusion that "the long-term adverse effects may well outweigh the short-term gains." (p. iii) This conclusion is perhaps the most important statement in the document.

The Colstrip plant project raises the problem of additive effects: the proposed plant is the first of several (or many) that will probably be built in the area in the near future. There do not seem to be adequate legal or institutional mechanisms either on a state or federal level to consider the additive effects until we are several steps further down the road. Ideally, the presently proposed plant should be evaluated not only as a separate phenomenon, but also as part of the overall picture. Clearly, the environmental impact of one plant may be "acceptable"; and the entire complex probably will not be acceptable. But, since one plant is a part of the whole, the decision to build, modify, or not to build one plant should not be made in a vacuum. The impact statement cannot justifiably be faulted on this point. We mention this problem to indicate that our evaluative procedures are not yet adequate to handle it. We face the danger of considering each increment of development separately and never evaluating the eventual aggregation of increments.

The preparation of this statement should have involved experts from more disciplines. Certain portions of the analysis are weak; biota, aesthetics and noise are several such sections. The statement concludes that stack emissions will cause the most significant impact (p.11) of the various parameters. This is probably true in this case, but it must be pointed out that a more comprehensive and rigorous study would justify this assumption beyond question or argument. It would also lead to more precise definition of the impacts from emissions. Studies now underway will be of considerable help (p. 24).

However, the absence of a complete range of disciplines probably results in a conservative estimate of the impacts in this case. In other words. it is probable that some adverse effects are undiscovered and hence total impacts could be worse than those portrayed.

There is an unevenness in the treatment of the various components of the entire facility. The power plant receives most attention; less attention is devoted to the mine and to urbanization, and even less is given to the transmission line and water consumption. Even if there are differences in legal jurisdiction

Exhibit 4

over the various components of the project, the obvious interdependencies of mine, plant, water and transmission lines would seem enough reason for the Statement to consider the impacts of all of these.

The Statement seems to confuse the importance of quantities of emissions with that of *environmental impact*. The former is really only a means for determining the latter. The latter is the real subject matter for a statement such as this. Unfortunately, this statement stresses quantities of emissions. What we really need to know is, what is the *effect* of the emissions? In some cases, the impact is not entirely known (for example, "The potential for damage to the ecosystem by flourides from the proposed Colstrip plant is not known at this time. At 77 lbs./day, more than 800,000 lbs. may be emitted over the 30-year life of the plant. . . ." (p.19)), but the responsibility of the authors is to define *impact* insofar as possible. "Effects on Ecosystem" (of air emissions) occupies only ½ a page, and contains little information. It does, however, caution that "over a period of years, the pollutants may build up to levels that seriously disrupt the ecosystem." (p.22) Clearly the subject matter under this heading should have occupied a major part of the statement. Although the authors are correct that exact impacts cannot be defined at this time, there is a good deal of information available as to the nature of expected impacts. In a later section, *some* of this information is discussed. (p. 29)

We feel that the final Environmental Impact Statement, and subsequent ones, should seek to define environmental impacts more precisely, and to focus on them.

The Statement would be improved with graphics showing physiography and ecosystems of the area, and other environmental parameters.

The current court interpretations that the 1970 Clean Air Act is to be construed by EPA to require non-degradation of existing air quality have not been discussed or dealt with in this Draft Environmental Impact Statement. This policy could have a significant effect on all proposed plants in the area, and should be considered seriously.

The impact statement should make clear the status of the project at the present time. From reading only this document, one would assume that the decision to build had not yet been made. However, we understand that the project is under construction.

It would also be useful to answer some procedural questions: what role will and should the impact statement and the Montana Environmental Quality Council play in the project? Is there any further decision-making procedure to be completed which might change the course of action now under way? In other words, is the project to be re-evaluated?

This Draft Statement is one of the more forthright which we have encountered. It is better than most which are prepared by the Federal government. The Montana Department of Health and Environmental Sciences is to be commended for this Statement.

Exhibit 4

II. Specific Comments

A. P. ii, Cutting Plant Load to Meet Standards. It is stated that "Reduction of plant load when these meteorological conditions arise could prevent the high one-hour levels" (of ambient sulfur oxides). Will such reduction be possible, or mandatory, so that "could" can be replaced by "will"? Furthermore is it possible to anticipate the meteorological conditions far enough in advance so that standards will not be violated?

B. P. 5, Particulate Size. It should be noted that the particulate emissions will be primarily in the range of 2 microns and smaller. These are most damaging to animal health, and remain in the air for prolonged periods. They act synergistically with SO_2 in the atmosphere, in effects on visibility, and in lungs, although precise effects are not known. This should also have been discussed in pages 12-19.

C. P. 12, Standards. It is stated that only in rare cases will either state or federal ambient air standards be violated. This bears further explanation -- how "rare," and is it legal to violate standards ever?

The impact statement refers to a statement by the Administrator of EPA to document the assertion that ambient air standards "are considered adequate." The Statement, to be complete, should mention that biologists (and others) consider the standards to be inadequate -- see, for example, the EPA and the BSFW Work Group reports to the Southwest Energy Study. The seriousness of this concern is emphasized by the fact that EPA is considering more rigid standards. It has been shown that emissions within the limitations of federal standards do significant damage to vegetation, hence to the entire food chain. See also our comment on non-degradation policy, in "General Comments."

D. P. 17, Potential Inaccuracies in Diffusion Modeling. It is stated that "wind channeling, impingement and other real-life phenomena" might cause higher SO_2 concentrations than predicted in the diffusion models. It is indicated that the same thing might prove true for other emission parameters. In view of the fact that the estimate that standards would be violated only in "rare" cases (p. 12) was obtained by diffusion modeling, and that charts in the Statement (pp. 9, 10) show that some expected emissions fall barely within standards, inaccuracies due to "real-life phenomena" could prove to be extremely significant. The Statement should emphasize this problem. The implication is that violations of standards are expected.

E. P. 21-22, Visibility. This section does not indicate if there is any physiographic "pocket" and inversion potential which could cause an accumulation of emissions over a period of time without dispersion. The implication of the comments on modeling is that this would not occur. The Statement should be more specific. The effects of any reduction in visibility should be related to a landscape analysis, including scenic vistas, visual corridors, etc.

Exhibit 4

F. P. 22, "Effects on Ecosystem." The "triggering" effects of certain actions could be significant. If vegetative species are reduced in any way, wind and water erosion could be triggered, especially in any extreme weather cycle such as drought.

G. P. 24, Studies Underway. It is noted that the Company intends to do a number of studies to assess the impact of their operation, and to save any endangered species or archeological materials on their sites. It would seem that the appropriate time to conduct these studies -- before construction -- is past. At least they should be conducted before operation of the plant. The Statement should review the status and findings of any studies underway.

H. P. 27, "Land Use." The impacted acreages of land use greatly exceed the direct acreage in many ways. For example, in aesthetics, the acreage affected is a "line-of-sight" area from which the mine, plant and transmission line can be seen. This is subject to rational analysis; the Forest Service has a computer program to determine "seen areas." If migratory patterns of some species of wildlife are involved, the effect on habitat of a road, mine or plant may involve many times the direct acreage of the plant.

The long-range possibility of changing the region from an agricultural to an industrial society also represents a land use effect far larger than the acreage directly affected.

The last paragraph on this page includes the sentence "Whether this is good or bad depends upon whether you are a golfer or a hunter." This misses the essence of environmental analysis very badly. Regardless of whether one is a golfer, a hunter or neither, a golf course which significantly disrupts ecological processes is not good; if it could have been located elsewhere with less environmental impact, it is less than good.

I. P. 29, Aquatic Ecosystems. Paragraph 4: Information on flows of the Yellowstone River should be furnished. An attempt should be made to define more thoroughly the impact of the project on aquatic ecosystems and on water resources.

J. P. 32, Noise. We disagree that quantitative values are meaningless. EPA and HUD have developed planning guidelines for noise using quantitative values. The workers'environment (plant and mine) includes probable exposure to certain decibel levels for certain periods of time. Will this lead to any loss of hearing? Other questions about noise can be quantified.

K. Pp. 34-36, Alternatives. The "alternatives" section does not really address the fact that the power from the Colstrip plant is headed for distant load centers, and that many potential alternatives could be taken at these distant points. For example, coal-fired plants could be built at the load centers instead of in Colstrip. The alternative "Not to Construct" should be expanded to include the alternative "Not to Construct in Colstrip." In addition, the alternative of energy conservation -- in its many forms -- has not been mentioned.

Exhibit 4

Alternatives of Advanced Power Cycles (or "combined power cycles," using gas and steam turbines) are not discussed, despite advantages in efficiencies and emission controls.

We note with interest that wind was formerly used in Montana to provide DC power. This source should be re-examined for modern use.

J. Pp. 37-40, Long-term vs. Short-term. The section on short-term uses provides excellent perspective. It presents the important long-term questions which so frequently are ignored in favor of the crisis of the moment. These four pages are worthy of separate publication and wide distribution -- the Colstrip plant is only a small part of the issues it addresses. Unless society -- the public, the decision-makers, the utility companies -- faces these far-reaching questions, it will have no basis for evaluating incremental short-term decisions such as the proposed plant at Colstrip.

RECEIVED
DEC 8 1972
ENVIRONMENTAL SCIENCES
DIVISION

In the matter of the Draft Environmental Impact Statement on the proposed Montana Power Company Electrical Generating Plant at Colstrip, Montana

Before: Air Quality Bureau, Montana State Department of Health and Environmental Sciences

Submitted by the Student Environmental Research Center

John McBride

William Tomlinson

Phillip Tourangeau

Exhibit 4

On review of the draft environmental impact statement, prepared for the two (2), 350 MW coal fired units of the steam electric generating plant presently being constructed at Colstrip, we find the statement generally inadequate, being insufficient, both in scope and depth to enable definition and quantification of impact. After detailed study of the draft statement we believe that the following questions should be considered in the final impact statement, and further that consideration of these questions is required under Section 69-6504 of the Montana Environmental Policy Act.

Administrative

What was the date declared for commencement of construction by applicant Montana Power on their application for a construction and operating permit?

What was the date of department receipt of application for construction permit as required under section 2 of Regulation 90-001 entitled Air Pollution Control Construction and Operating Permits?

Section I (A) (1)

It is stated that "this complex...will provide electricity for Montana users and for shipment to the load centers of the Pacific Northwest." Of this power supply what percent will be utilized in state? What percent will be consumed in the Pacific Northwest load centers? (please itemize)

Is this plant required under projected levels of growth for Montana?

Exhibit 4

It is stated in the impact statement that, "Mine-mouth" plants, which are located near enough to the coal for conveyor or short-distance rail transfer of coal, are presently favored by economic, technical, and environmental parameters, at least from the owners' standpoint." How and to what degree are "mine-mouth" plants favored over load center development employing either fossil fuel based generation, nuclear or other alternative energy conversion technology?

How will the venturi scrubbers remove gaseous fluorides and heavy metals? (Cite evidence)

Section I(A) 2

What is the applicant Montana Power Company's water appropriation claim at Nichols?

What percent of the minimum flow and average flow of the Yellowstone at the point of withdrawl is Montana Power's appropriation?

What percent of the appropriation is represented by the stated withdrawal of 8000 gallons per minute?

What percent of the minimum flow and average flow of the Yellowstone at the point of withdrawal is this?

What is the maximum capacity of the proposed water supply system? (Both the 24 inch pipe and larger pipes up to 60 inches)

What will be the impact on down stream water quality by the withdrawal of the 8,000 gallons per minute as proposed herein?

What will be the impact on the down stream water quality by the withdrawal of the entire Montana Power appropriation?

Exhibit 4

An 8,000 gallon per minute flow will deliver 13,058 acre feet of water per year. According to the flow diagram appended to section I, the water consumption of the two (2) units will be 13,068 acre feet per year. Assuming a 26-inch per year evaporation rate approximately 65 acre feet per year will be evaporated from the surge pond. Thus the water supply to the Colstrip generating facility as described is inadequate. Please comment. (Give a detailed water balance from intake through generation, cooling tower and settling ponds.)

What are the operating characteristics of the water supply system? (Size of pump, exact diameter of pipe, number of pumping stations, etc.)

What will be the environmental impacts associated with the construction and continued maintenance of this pipeline?

How will the area disturbed by the construction of the pipeline and pumping stations be reclaimed?

Has right of way acquisition begun for the pipeline?

Will the pipeline cross any sections of state or federal land?

If the answer to the preceeding question is affirmative have the easements for these parcels of land been obtained?

Does the applicant expect to exercise the powers of condemnation in securing pipeline right of way?

Section I (A) (3)

What are the environmental impacts of the powerlines associated with the generation complex?

Exhibit 4

Section I (A) (4)

What precautions will be undertaken to control particulate air pollution from the crushed coal stockpiles?

What percent of the mined land will be reclaimed each year?

Will additional lands, not presently held by the Western Energy Co. be required for their expanded mining operation required under this proposal?

Section I (A) (5)

What is the physiographic setting of the power plant and requisite facilities? (On suitable topographic maps or air photos locate the two (2) thermal electric generators, cooling towers, aquaduct, pumping stations, transmission lines, settling or ash ponds, surge ponds, coal storage areas, strip mines, haul roads, and housing developments.)

What are the qualifications of Ron R. White and Company?

Of the total cost of the Colstrip facility what will be the cost of the abatement equipment? (Include cost description of all abatement equipment.)

Section II (A)

The sandstone caprocks are considered by many to be one of the most outstanding topographic features of the Colstrip area. What are the unique landscape features of the Colstrip area?

Section II (B)

Please clarify what is meant by the Tongue River Indian Reservation?

Section II (D)

Have archeology surveys been conducted on the steam generator site, mine site and the site of all requisite facilities?

Exhibit 4

What percent of power generated will be lost in transmission to the Billings substation and to west coast load centers?

Will the ozone generated by the powerlines react synergistically with sulfur dioxide from the power plant to create an air pollution problem?

What route is to be selected for the two additional 230 KV powerlines that will be constructed?

Will the two (2) additional transmission lines cross any state or federal land?

Has right of way acquisition begun for the two additional powerlines?

Does the applicant expect to exercise the powers of condemnation in securing transmission line right of way?

On what date did construction commence on the transmission line currently under construction?

Has all the right of way been secured for the transmission line currently under construction?

Does the transmission line currently under construction cross any state or federal land?

If the answer to the preceeding question is affirmative have the easements for these parcels of land been obtained?

Has the applicant exercised the powers of condemnation in securing any portion of right of way for the transmission line under construction?

Exhibit 4

What effect will the increased travel on unpaved streets, mining and construction have on particulate levels in the town of Colstrip?

What is the basis for the statement, "It is anticipated then that an annual geometric mean for the area may approach 50-60 ug/m^3?

Section III (A) (3)

What is the accuracy of the sulfation plate method for determining SO_2?

How can the predicted Annual Average SO_2 concentration after the power plant is built be less than present background levels?

Please detail and document the computer diffusion model used to predict pollution levels by the State and EPA. (Perhaps this could best be done by including the entire model and input data)

Can particulate and NO_x values be determined from the SO_2 model?

Have baseline studies been conducted to determine the particle size and number density in the ambient air? What are the results?

What will the particle size and number density be in the stack gases?

What influence will these particles have on the base line conditions?

Section III (A) (5)

How can the environmental impacts of trace elements be assessed without a comprehensive statistically significant elemental analysis of the coal?

We are particularly concerned with the fluoride concentration reported by Truesdale Labs. Analyses from the Southwest Energy Study

Exhibit 4

If the answer to the above question is affirmative please describe the location and contents of all finds?

Section II (F)

The statement made on page 8, titled Meteorology can only be considered a climatic description of the area. The following Meteorologic parameters are necessary to evaluate air pollution potential and to provide baseline data for climatic modification, resulting from the development.

- Mean annual and monthly temperature and precepitation
- Wind speed and wind direction both at ground level and for the upper atmosphere
- Standard deviation for both wind speed and wind direction for both ground level and upper atmosphere
- Annual and monthly average relative humidity at standard observation times
- Inversion frequency and duration as evidenced by temperature differential at varying elevations and barometric pressures
- Solar radiation
- Visibility and cloud ceiling

Section III (A) (1)

The aquaduct, transmission lines and surge ponds also have primary impacts on the environment.

Section III (A) (2)

How was the estimate of 15 ug/m^3 total suspended particulate derived?

What are the present particulate levels in the town of Colstrip?

Exhibit 4

indicate levels much higher as do preliminary analysis on Montana coal at the University of Montana. As vegetation is particularly sensitive to fluoride levels, an accurate analysis must be made.

What are the qualifications of Truesdale Labs?

How are uranium and thorium removed from the effluent gases?

Section III (A) (6)

Explain paragraph one (1).

What effect will water vapor and heat emissions have on relative humidity, fog incidence, cloud ceiling and incoming solar radiation?

What effect will the localized heat island associated with the power plant have on the surrounding ecosystem?

Section III (A) (7)

We cannot agree with the first sentence following the quotation from the First Annual Report of the Council On Environmental Quality. Relative humidity near the power plant will be high and will probably be near 100 percent during the winter months. Under these conditions visibility reduction will definitely take place. The initial contention is also contradicted by the last sentence of the paragraph, "It is possible that under meteorological conditions such as high humidity a marked increase in fog occurrence will be observed due to the water emission."

Section III (A) (8)

There are numerous studies on the effects of SO_2, NO_x, particulates, etc. on ecosystems. It is certainly possible to predict some of

Exhibit 4

the effects of these pollutants. We can only stress that this section should be greatly expanded and should include a review of the pertinent literature on the effects of these pollutants.

Section III (B)

What is the past record of the designated contractors in meeting their guarantees on boiler and emission control facilities?

Section III (C)

What facilities are employed by West Associates in performing trace metal coal analysis? (What specific chemical and physical determinations are employed?)

Does the public have access to the special Environmental Studies performed by the applicant and subcontractors?

Does the public have access to all monitoring data collected by the company?

How will endangered species and archaeological materials be saved for posterity?

Section III (D) (1) (a)

What methods of dust supression will be employed in the handling and storage of flyash?

Section III (D) (1) (b)

Has the effect of boron in the flyash been appraised?

What solubility studies have been preformed on the flyash?

Exhibit 4

Section III (D) (1) (c)

What studies have been undertaken to determine ground water contamination from flyash and settling pond leaching?

Section III (D) (1) (d)

The discussion of sewage treatment seems to be quite sketchy and numerous questions arise. (Please give a detailed description of proposed sewage facilities and particularly what sewage treatment facilities will be available for the construction work force.)

Please include in the discussion on the Colstrip sewage system the "Water Quality Management Interim Plan for Colstrip, Montana" as prepared by the department and the grant application and granting stipulation for the funding of that system under EPA.

Section III (D) (4)

Explain pages 29 - 31.

Section IV

The following are also adverse environmental effects which cannot be avoided should the proposed facility be implemented:

1. New road construction and the upgrading of existing roads.
2. If the proposed facility just meets ambient air standards further industrial development will be precluded.

Section V

The discussion of alternatives is inadequate. The impact of non development must be considered and additionally the alternative choices for the proposed facility should be considered. (i.e. wet versus dry

Exhibit 4

cooling towers, de-ashing coal, desulfurization of coal, advanced SO_2 emission controls, etc.)

The discussion of alternative technologies should be greatly expanded particularly in reference to why each choice was eliminated.

Mr. Don Holtz, Chief
Air Quality Bureau
Environmental Sciences Division
State Department of Health and Environmental Sciences
Helena, Montana 59601

Dear Mr. Holtz:

Thank you for the opportunity to review the draft "Environmental Impact Statement on the Proposed Montana Power Company Electrical Generating Plant at Colstrip, Montana", dated October 1972.

We offer the following comment for possible inclusion in your report:

Page IV. Pipeline. The size of the pipeline (diameter) should be shown since it is a critical factor in estimating the many unknowns associated with possible effects of the development. If it is only 24 inches diameter as shown as the minimum, it can be assumed that this environmental impact statement reflects the needs of this 700 mw plant. If, however, the diameter is to be 60 inches as reported likely (Billings Gazette, 12/1/72), we are compelled to conclude that the ultimate development associated with the construction and development in this vicinity will be many times greater, perhaps nine times greater.

The effects upon the river fishery of a diversion of the magnitudes herein considered is not likely to be significantly detrimental. However, intake structures should be screened or so designed as to preclude entrance of fish now in the Yellowstone River.

Water Consumption. It is much more meaningful to people (in the West, at least) to show water volumes or rates of flow in terms of acre feet (af) or cubic feet per second (cfs). Thus, we suggest that the 8,000 gallons per minute be shown as 17.8 cfs, and 12,816 af per year.

Page 2. Pipeline and Water Supply. Comments immediately above are applicable here and this paragraph should be revised accordingly. It would be appropriate to suggest that the surge pond be constructed so that 30 percent or more is over 15 feet deep. This would then have potential

Exhibit 4

value for fish and fishing. Its value for this purpose may hinge on other factors ie., rate of water change, problems associated with screening intakes and outlets, and fish management (fish planting, rough fish control, and regulation of fishing).

Page 2. Transmission Lines. All power lines should be so designed and constructed that they will not present an electrocution hazard to raptors or other birds.

River crossings are particularly dangerous to waterfowl that move up and down stream, particularly during migration periods.

Page 8. E. Recreation. This paragraph ought to be headed Recreation, Fish and Wildlife. We suggest that it be written as follows - "Southeastern Montana offers limited opportunities for outdoor recreation. Campgrounds have been established in the Custer National Forest and on the Indian Reservations, but opportunities for boating, sailing and swimming are few, and winter sports and other organized activities such as golf, hiking, nature study, and summer group camp activities are scarce. However, all of these are available in some measure within 200 miles west.

The pronghorn antelope and mule deer provide excellent big game hunting of national importance to residents and non-residents. Whitetailed deer are common along major watercourses and are hunted in proportion to their limited numbers. Some of the State's best ring-necked pheasant populations are found along the Yellowstone River, and particularly in the nearby side drainages. Hungarian partridge, sage grouse, and sharptailed grouse are common and where habitat is suitable provide a moderate amount of hunting, however, almost none of it by non-residents. A fair fishery for walleye pike and sanger is provided by the Yellowstone River and major tributaries. Trout are seldom caught below Billings on the Yellowstone River or Hardin on the Bighorn River. A few trout are to be found in farm ponds having adequate depth and other conditions favoring cooler water temperatures. There is an important paddlefish population in the Yellowstone River below Forsyth and fishing for this species has increased greatly in the past ten years."

Page 14. 2. Particulate. The second paragraph top page 14, should be strengthened. We are concerned that dust from the mining operations, including the trucking of the coal to the plant site, along with the particulate matter from the plant, will be deposited on vegetation over a wide area. Prevailing winds will be instrumental in carrying this dust. Vegetation coated by dust and particulates will either die or at least be unpalatable to both livestock and wildlife.

Page 14. 3. Sulfur Oxides. Sulfur oxide emissions of 6,820 per hour from furnace stacks of the proposed project is a serious threat to the

Exhibit 4

existing environment and additional efforts should be made to improve emission control more than the 39 percent proposed.

Page 20. 6. Effects of Water and Heat Emission from the Power Plant. The bottom paragraph would be much more meaningful if the water volume and rate were conventionally expressed. We suggest the "3,300,000 pounds per hour" be revised to say "395,000 gallons per hour (14.7 cfs) or 10,600 acre feet per year". The above comments apply to the top paragraph on page 26 as well. (Note our related comment for pages IV and 2.)

We feel very confident that discharges to the atmosphere in this magnitude at relatively low levels will result in very significant climatic changes in the direction of prevailing air currents. The individual impact of this primary unit (of 700 mw) may not be significant, but cumulatively with prospective full development precipitation may be very substantial. Erosion problems in nearby drainage ways may be accelerated and the effects upon both fish and wildlife habitats could be significant. Some of the effects might be expected to be beneficial, others could be detrimental unless measures are taken to offset them.

Page 29. 3. Impact on Flora and Fauna. We do not agree that " . . . hunters, dogs and so on will have a damaging effect . . ." Although there may be some increase in hunting pressure, the take of deer and antelope, the primary species of concern, is carefully managed by hunting areas and excessive use can and probably will be avoided. We suggest deletion of all of the first sentence of the second full paragraph on page 29.

This section should discuss plans to offset damage to the flora and fauna, in particular, the details concerning land reclamation. Among other things, land reclamation should include consideration for the construction of fish ponds, or reservoirs suitable for future management for public fishing by the Montana Fish and Game Department.

We believe that steam electric power generation stations based on the coal deposits in Eastern Montana should not be constructed until a better total evaluation of their potential impact on the environment can be made.

Sincerely,

Wilfred D. Crabb
Acting Area Manager

Mr. Don Holtz
Chief, Air Quality Bureau
State of Montana Department of Health and
Environmental Sciences
Helena, MT 59601

Dear Mr. Holtz:

Your draft Environmental Impact Statement for the proposed Colstrip Power Plant has been reviewed by this office.

The following is a consortium of views expressed by individuals having expertise in a wide variety of disciplines. The greatest concern expressed by these people does not relate specifically to your Environmental Impact Statement, but is one which identifies the need for a more comprehensive study to assure orderly development and the production of needed power from the entire Fort Union Formation Area in a manner which will prevent or minimize degradation to the environment, traditional uses and human resources of the area affected.

We believe that an approval for construction and operation of the first two relatively small facilities discussed in your Environmental Impact Statement would act as a precedent setting action for additional plants in the area. An analysis of the cumulative effects of the ultimate amount of mining, number and size of plants is needed before piecemeal development is undertaken.

Although the first two plants proposed for the Colstrip area are large when compared with existing electrical generation facilities in Montana, they represent a very minor portion of the possible number and size of plants now being considered for the utilization of coal in the Fort Union Formation. The North Central Power Study, as an example, proposes development up to 53,000 MW in the area. The 53,000 MW capacity is 75 times as great as the first two plants proposed by Montana Power.

The first two plants at Colstrip propose the construction of a 30-mile aqueduct from the Yellowstone River and two additional powerlines to the Billings area. If there are to be additional plants in the area, a more comprehensive analysis should be made to determine if larger

Exhibit 4

capacity aqueducts and power transmission lines would be more economical and create less total adverse environmental and social effect and impact. The preferred location of these lines needs to be identified along with alternates in order to adequately evaluate their impacts.

Your Environmental Impact Statement points out that Montana Power is presently considering additional units at the Colstrip location. It is our understanding that two more plants are being planned for completion by September 1978 and 1979, respectively. Each of these plants would equal the total generation capacity of the two plants discussed in your Environmental Impact Study. Information made available to us indicates that 350 MW of the 700 MW to be produced from the first two proposed plants at Colstrip would be wheeled to the West Coast. This same material shows that an additional 1,050 MW would go west from the second two plants being planned by Montana Power and Puget Sound Power and Light. Thus far, we have been unable to determine where the balance of available power will be directed. We are anxious to find this out since it is possible that transmission lines might be planned which would cross National Forest lands east of Colstrip.

The environmental statement indicates "the rapid growth of electrical energy consumption in the United States at this time is an indication of our dependence on this comodity." "This demand is presently growing in such manner that consumption doubles every ten years."

Estimates of future electrical power loads in the Pacific Northwest is estimated to double about every 12 years. The Pacific Northwest region in order to meet its future power needs will in all probability have to shift its reliance on hydroelectric generation to a system made up of hydroelectric and thermal generation. Major load centers of the Pacific Northwest are located along the Pacific slope with hydro-generation plants located east of the Cascade Mountains. Much of the needed thermal generation may also come from east of the Cascades and also east of the Continental Divide.

The electricity from the Colstrip project as discussed in your Environmental Impact Statement would be transfered by three 230 K.V. transmission lines originating in the plant switch yard and extending westerly to the Billings area. These lines will terminate as a new substation to be added to the Montana Power Company integrated system north of Billings, Montana. There is no evaluation as to the possible transmission line corridors, transmission line capacities, and the environmental impacts involved in moving the needed electricity produced to the Pacific Northwest load centers. In the Pacific Northwest where present peak loads are approaching 20,000 MW, the right-of-way problem can be somewhat reduced by the replacement of existing lines with higher capacity lines. As transmission voltage increases the land use per kilowatt for transmission right-of-way decreases. A 230 K.V. alternating current line carries about 300 MW,

while a 500 K.V. alternating current line carries on the order of 1,250 to 1,500 MW, about five times as much power, yet the 500 K.V. lines require only 125'-150' of right-of-way--slightly more than the 125' for a 230 K.V. line.

It would appear that, should the development of Montana coal become as significant as is presently committed by the environmental statement for the Colstrip project, power transmission corridors will be needed across the Continental Divide to reach the Pacific Northwest load centers and especially the coastal area of the region. Western transmission of generation from Colstrip to the load centers involved could involve several existing and potential transmission corridor possibilities. These possibilities are directly related to major existing and proposed transmission grid systems and known power marketing responsibilities. Some prominent transmission line corridor considerations are:

1. Colstrip, Montana, west to Anaconda, Montana, westerly across the Saphire Range and Bitterroot Mountains via the Magruder Corridor to south of Lewiston, Idaho, westerly to the load centers.

2. From Anaconda, Montana, to Hot Springs, Montana, to Spokane, Washington; Grand Coulee, Washington, south and west to load centers.

3. From Anaconda, Montana, to Hot Springs, Montana, following the present Dworshak Hot Springs Transmission Line to west of Dworshak Dam near Ahsahka, Idaho, via the lower Snake River area to the load centers.

The above possible transmission line corridors could involve directly and indirectly National Forest system lands located on eight National Forests.

In considering the above or other possible existing or potential transmission line corridors where National Forest system lands are involved, there are land and resource management considerations involved which must be solved and alternatives considered before final decisions and authorizations can be made. Comprehensive land and resource evaluations and analysis processes must be completed to ascertain that the proposed transmission line corridor(s) is consistent with other planned activities and would not create any foreseeable serious adverse consequences concerning long term management. Determination must be made that the portion of the considered corridor located on intermingled or adjacent land would not adversely and seriously offset important National Forest system values or preclude the achieving of National Forest objectives. Also, determination must be made that the proposed corridor location on National Forest system lands would not adversely or seriously affect the environmental quality of other intermingled or adjacent land. Also included are primitive area studies, social and economic impacts, pending legislative action, environmental statements required by the National Environmental Policy Act, public involvement, coordination between all

utilities including public, private, and Federal agencies involved in the production transmission and marketing of electricity. Until the above is accomplished and all alternatives considered, all land options related to the allocation National Forest lands from a diminishing land base must be kept open. Determination of locations and authorization for transmission line corridor(s) on National Forest land such as discussed above would require approximately 5 years.

National Forest lands nearest to the proposed Colstrip plants lie approximately 20 to 25 miles to the east. The prevailing westerly winds passing through the Colstrip area also pass over the Ashland Division of the Custer National Forest. We are, therefore, concerned about stack emissions from the proposed plants.

The projection for uncontrolled emissions of 3.2 pounds per hour of fluorides and 0.23 pounds per hour of mercury are particularly worrisome since they are cumulative poisons and affect plants and animals at relatively low concentrations. Livestock develop fluorosis if grazing is done on vegetation containing more than 35 ppm fluoride.

If the second two plants being planned by Montana Power are constructed an should they produce fluoride emissions at an equal rate, a total of approximately 42 tons per year could be created. The effect of this volume of fluorides on the downwind livestock industry is not known, but would no doubt be significant.

The projected emission of 82 tons per day of sulfur dioxide by the first two small plants would degrade air quality seriously. There is need to identify the amount of sulfurous and sulfuric acids that would be deposited downwind from the plants before construction is permitted. The effects of this large amount of emissions is the important thing to identify. It matters little if the proposed plants individually comply with State and Federal air quality standards based on pounds per million BTU of input.

In summary, I would like to reemphasize the need for comprehensive area-wide study to assure the orderly management of the coal resources within the entire Fort Union Formation to help meet the energy needs of this country in a manner which is in harmony with a quality environment.

Sincerely,

Warren G. Davis

for STEVE YURICH
Regional Forester

Board of Health Building

Dear Mr. Holtz:

We have reviewed the Draft Environmental Statement for the proposed Montana Power Company Electrical Generating Plant at Colstrip, Montana, and wish to comment thereon.

We are concerned over the proposal to bury flyash, bottom ash, and economizer ash in "worked out" strip mines and feel that the discussion of the impact of the proposal (on page 25) is inadequate for the following reasons:

1. A complete analysis of the material and of its trace metal content should be requested before a decision is made concerning burial. Otherwise, any adverse impacts such as ground water contamination might be irreversible before they were discovered.

2. There is no discussion of the affect of fly ash burial on future mining for lower seams and the subsequent reclamation of ash contaminated spoils.

3. There is no discussion of other alternatives. We understand that some generating facilities presently sell this material to cement manufactors for industrial use in cement processing, cinder blocks, etc. This alternative would eliminate any possible adverse effects and would prevent the "wasting" of a portion of Montana's coal resource.

Sincerely,

John Henson

RECEIVED
DEC 19 19[illegible]
ENVIRO[illegible]
DIVISION

Dear Mr. Holtz:

We have reviewed the draft environmental impact statement for the proposed Colstrip Power Plant and would like to offer the following comments:

1. With regard to possible alternatives nothing was mentioned about alternative plant designs - e.g. different size or type of plant with different water requirements.

In particular we would like to see the final impact statement discuss the advantages and disadvantages of utilizing dry-cooling towers as an alternative to the proposed wet-type cooling towers as a means of disposing of waste heat from the generating plant. Dry-type cooling systems eject waste heat directly to the atmosphere without an evaporative loss of water.

Studies indicate that dry-cooling towers require only one percent of the water that wet-cooling requires; therefore, it may be possible to reduce the consumptive water use of the Colstrip plant if dry-cooling towers are used. ("North Central Power Study", Phase I, Vol. II, pg. XI-13, 1971.)

In addition direct savings to the utility may be possible with dry-cooling. Examples are: (1) reduced fuel cost due to greater flexibility of plant location with the dry-cooling system, (2) possible transmission cost savings as a result of greater flexibility of plant location, and (3) possible savings in cooling-water costs. ("Dry-Type Cooling Towers for Steam Electric Generating Plants," a paper by John P. Rossie, R. W. Beck and Associates, 1971.)

Advantages to the public sector are also apparent and, although presently unquantifiable, are obviously important. Two advantages are: the possible reduction in future water use conflicts between agriculture and the energy industry and the reduction of pressure to build storage reservoirs to provide water for the energy industry.

Exhibit 4

2. The size of the pipeline is not well defined. The statement mentions only a minimum size of 24 inches. The size could be an important factor on total impact.

3. The impact statement indicates that approximately 8,000 gallons per minute from the Yellowstone river will be needed for operation of the plant with no water being returned. Since Montana Power Company filed a notice of appropriation on December 22, 1970 for 250 cu. ft. sec. or 112,200 gal. per minute to be transported to the vicinity of Colstrip by a 60" diameter pipe to be constructed by 1974, does this mean that other plants are being contemplated in addition to the one being built? What does 8,000 gal. per minute or 112,200 gal. per minute from the Yellowstone mean in terms of percent of minimum flow and average flow of the Yellowstone at the point of diversion? What impact would the withdrawal of such quantities of water have on water quality or on the quantity available for downstream users?

4. Other than the statement on page 2 with regard to "common corridors where feasible" for two transmission lines to be built in 1975 and 1976, what considerations have been given to routing of pipelines and transmission lines? Have alternative routes been thoroughly investigated and has a common routing corridor been considered? Has there been consultation with other companies having future plans in the area concerning the possibility of a common aqueduct for water supply? What are the impacts of contemplated pipelines and transmission lines?

5. It appears to us that ash from the plant may have some deleterious soluble compounds. We would be interested in receiving the results of the investigations to be conducted by the Department of Health and the Montana Power Company concerning this potential problem.

6. What class of agricultural land by Soil Conservation Service standards will this plant occupy? Does the 1365 acres proposed for the plant occupy prime agricultural land? Does the proposed plant site location plus supporting facilities and activities represent a planned land use consistent with the needs and desires of the county, southeastern Montana or Montana?

Thank you for the opportunity to comment.

Sincerely,

Gary J. Wicks

and Environmental Sciences
Cogswell Building
Helena, Montana 59601

Gentlemen:

Our agency has reviewed the draft Environmental Impact Statement prepared by your Department concerning the proposed Montana Power Company electrical generating plant at Colstrip, Montana, and has compiled the following comments:

1. Description of the Proposed Action and Assessment

Considerable detail was developed pertaining to the activities surrounding the plant site and mine location. However, information concerning the three proposed 230 KV transmission lines that will originate at the plant site and cross the state towards the Billings area was very limited. Also, little discussion was focused on the proposed 31 mile aqueduct which will divert 8,000 gallons of water per minute from the Yellowstone River. The impact of the three power lines and the aqueduct should have been fully evaluated in conjunction with the entire project operation to enable an in-depth assessment of the total magnitude of the project as proposed. With this information on hand, a more realistic approach to possible alternatives and the various tradeoffs involved in each alternative could have been developed and assessed.

An incremental assessment and/or licensing approach may preclude full assessment of the entire project and viable alternatives because such an assessment could lack comprehensive information needed at the crucial decision-making stages.

2. Impacts on the Environment

a. Ecological Impacts from Emissions:

It appears that further study of the items listed below are needed to determine both their short term and cumulative effects on the living and non-living components of the environment:

Exhibit 4

Pollutants - Air
Particulates
Sulfur Oxide
Nitrogen Oxide
Fluorides
Mercury
Other trace and/or radioactive substances

Studies and data would also appear to be needed on the wind flow and climatological patterns in the Colstrip area. Some questions meriting consideration are noted as follows: What areas will be affected by the plant emissions? Will the emissions drift towards Broadus and the Black Hills? Will they drift into the Yellowstone Valley? What effect, if any, will inversion layers have on the stack emissions and the steam which is emanating from the cooling towers?

b. Impacts Other than Emissions

From the draft statement, it was summarized that the project proposal would physically affect the following acreages of land:

Mine	2,000 acres	
Plant Site	1,365 acres	(maximum)
Rights-of-Way	2,900 acres	

The text covered the plant site in considerable detail while the proposed mine field, water pipe line and transmission lines were treated in a more limited fashion.

The design, construction method, and routes of pipe line and transmission line rights-of-way would have been helpful. This discussion should have included such items as right-of-way widths, the type of topography and vegetative cover disturbed, and the measures considered for each affected resource along the primary and alternative routes selected.

One critical factor meriting considerable discussion and not covered in the mine field operation was the potential effect, if any, of strip mining on the area's water bearing aquifers. If adverse effects are possible, or anticipated, what corrective measures, if any, could be taken to safeguard or alleviate the situation? This potential environmental impact could have substantive local and regional effects concerning current and future ground water quality and utilization practices.

Exhibit 4

3. People Influence or Impact

The text discussed this topic but several questions still persist and should be addressed in this type of environmental assessment. In the short run, during the construction phase, 800-900 workers and their families, if any, will be involved in the proposed project. However, during the operational phase, this number will drop to approximately 100 full time employees.and their families. How will the local amenities and natural resources be affected by such an influx of population and its inherent characteristics? How will the project affect area housing, public services such as education and law enforcement, professional services such as medical needs, transportation services, and facilities, public administration goals, financing services and planning and overall outdoor oriented public recreation? The short and long term implications and cumulative effects concerning this proposed project and its people influence and impacts are, therefore, of critical importance.

4. Impacts on Flora and Fauna

Plant and animal life should have been considered along the various proposed right-of-way routes to supplement the discussion of these factors at the plant and mine site locations. Also, more information concerning the specific vegetative types and wildlife species affected by the proposed project would have been desirable to enable an assessment of the short term and long range effects of the overall development proposal in this relatively remote area of the state.

5. Alternatives

Within the alternatives section, an alternative not considered and meriting consideration would have been the locating of the plant site closer to the power demand centers. Although this action would not mitigate the total impacts of the project, it would provide an expanded forum for discussing and weighing the local and regional tradeoffs involved concerning the proposal under consideration.

Thank you for the opportunity to review the draft.

Sincerely,

Edwin Zaidlicz

Gentlemen:

Reference is made to the draft Environmental Impact Statement on a proposed Montana Power Company electrical generating plant at Colstrip, Montana. Comments were collected from several members of our staff and have been consolidated and can be summarized as follows:

It is difficult to provide an objective evaluation of the statement without benefit of data furnished by the Montana Power Company in its permit application. However, we concur generally with the statement in its overall evaluation of the probably impact on the environment. As we read Part III of the Statement, the proposed 700 M.W. plant is expected to operate within federal and state standards for emissions and ambient air levels (except for ambient sulphur oxides which may, infrequently, exceed established levels).

We would suggest that an additional alternative to the proposed action concerns building the plant in another area of Montana or in an adjacent state or closer to load centers. It would be useful to evaluate this alternative for the purpose of validating data provided by the sponsor and to determine what the impact of this size plant might be if located in an area where industrialization has already taken place, in terms of the environment and social and economic impacts, etc., or where there are marked differences in climate and meteorological phenomena from that of southeastern Montana. Also, in the final EIS on this proposal, a dichotomy might be developed which would expand the alternative of not building the plant at all - i.e. a moratorium vs. the opportunity to closely monitor the construction and operation of the project under consideration, and use it as a "test bed" to determine if future expansions are feasible at all. This discussion might consider the extend of risk involved in permitting the 700 M.W. plant as setting a precedent for unlimited expansion. Would it be reasonable to support a moratorium now rather than look upon the 700 M.W. plant as a situation which would tell us whether larger and more numerous plants of this type could be tolerated?

In future draft statements of this type, the Department of Planning and Economic Development and other state agencies should be called upon to contribute to the portions dealing with strengths and weaknesses of the political, social, and economic institutions of the area and the capabilities of those institutions to

Exhibit 4

absorb impacts expected from the proposed development. We do not see wholly "adverse environmental effects which cannot be avoided" (see Part IV) in population increases of the magnitude (around 2,000) facing Colstrip, for example. Such a facility as this might well provide job opportunities and living standards adequate to retain some of the large numbers of our young people who now leave Montana because there is no future for them in remaining here. Also, if the penalty on the environment is not excessive, we question whether it would be an adverse effect for an increased flow of capital and goods to occur in the vicinity of the plant. Permit these examples to serve to illustrate why we suggest that more inputs perhaps might have been considered.

There are good reasons to raise the larger issue of strip mining in eastern Montana from a long-term view of what extensive coal development portends. But that is a task calling for a different kind of review and a much more comprehensive study and analysis. It requires that the entire spectrum of electrical energy production using strippable coal be examined in the context of the potential and the threat to eastern Montana, the State, and the Nation. Over the long term and under conditions of expansion, there will unquestionably loom grave threats and considerable promise. We would suggest that these disparate conditions cannot be related and compared with finality based merely upon this proposal for a first "mine-mouth" plant. The kind of broad review which addresses the total issue is a main function of the Coal Task Force. It is vital that the Task Force enjoy the positive cooperation by all agencies and that it arrives at well-reasoned conclusions as quickly as possible.

Thank you for the opportunity to review and comment.

Sincerely,

Lloyd F. Meyer

State Dept. of Health
Air Quality Bureau
Helena, Mont.

Dear Sirs:

I support the construction of a power generating plant at Colstrip by the Montana Power Co. I also support construction of other generating plants as proposed by the company and others.

Montana desperately needs investment money. The Montana Power plant is one example of this type of money. Montana must encourage a climate which encourages development in order for Montana to realize its fair share of plant investment money related to coal mining. Further, Montana must espouse a strong, unequivocal statement supporting coal development and processing. This is an absolute first step if Montana is to realize benefits of her resources and if her people are to realize the benefits of the many jobs that go with it.

The need for more electricity is obvious. The "energy crisis" is a fact. According to a noted economist-writer, Donald Rogers, writing in Economy Report, "there will be a fuel crisis in the Northeast this winter. Natural gas will be in short supply. And electricity will be in short supply." Don't forget, he reminds us, that every major city in the nation's upper latitudes has for four years suffered "brownouts" during the hottest and coldest days. And the shortage is expected to get worse.

We may, as we are inclined to do in Montana, say, what the hell do we care about the northeast part of our country. (One wonders how we might react to a similar statement directed to US by THEM!) We care because we live in the United States. And if our area happens to have the resources available to help out, by all means we are obligated to so do. But "doing something about an energy crisis" is not easy. It requires vast investment money. It requires new technology. It requires transmission of large quantities of power...and the right kind of power...large quantities of base load power to augment the user requirements of other power companies in different parts of the country. Montana can help fill the bill on all counts by development of her coal resources. Private industry has the capability and the desire to go ahead and fill the need, so why do we tarry and seek a stoppage? In the name of the environment? Bosh!

Pollution efforts will be overcome by the technology of industry. Not by some autocrat sitting in some agency office in Helena or Washington D.C. As Peter Drucker tells us: "...the sewage treatment plants(as an example) that are urgently needed all over the world will be designed, built and kept running not by purity of heart, ballads, or Earth Days but by crews of crew-cut engineers working in very large organizations, whether businesses, research labs or government agencies." We must remember that any pollution is controllable - but at a price. Practically every environmental task demands huge amounts of electrical energy, way beyond anything now available. And

cont.

why do we indulge in the grossest hypocrisy in this matter. On the one hand we say we are serious about pollution control programs - whether waste, emissions, sewage or pesticides - WHILE WE REFUSE TO BUILD THE POWER PLANTS WE NEED TO RESOLVE THE PROBLEMS. We need to put first things first and generation of electricity is that "first."

In the same newspaper that tells me of the peril of coal development for Eastern Montana is another article, tucked on the bottom of page 20 in small headline package: "Montana's jobless rate continues to climb...by February more than 10% of the state's civilian work force will be unemployed." This is another bit of hypocrisy we can do without. It's time we got serious about the problem of job opportunity in Montana.

The environmental doomsayers have reigned long enough. Now it's time to go to work and solve the problems facing Montana and the nation.

Sincerely,

Aubrey D. Larson

Dear Sir:

I am becoming increasingly disturbed by the campaigns being waged by some environmentalist groups and the Billings Gazette over strip mining and power production.

Those of us who keep up with the energy situation in this country know that we are headed for a period of energy shortage if positive steps are not taken very soon. I have enclosed a copy of the conclusions drawn in a study conducted by the Chase Manhatten Bank entitled "Outlook for Energy in the United States to 1985." I believe these conclusions sum up our situation very well.

As a result of this energy pinch, Montana is faced with what I believe to be a golden opportunity. We have here an opportunity not only to help alleviate the energy crisis but to bolster our own economy at the same time. I believe that with proper control, by that I mean reasonable polution limits and realistic strip mining laws, we can all benefit from the orderly harvesting of the coal resources that we have here in Montana.

In the past few years it seems that any time some new idea or situation arises, there are many boistrous shouts against change. Most of these are negative scare tactics and have little basis in fact. I only hope that we are not overcome by such propaganda.

In the case of the Montana Power plant at Coalstrip, I hope that you will grant them a license to operate their proposed plant if they meet the polution standards now on the books. I feel it is a step in the right direction and should be encouraged by all.

Respectfully yours,

Wes Eyer

Gentlemen:

I am a native Montanan - born in Ronan in 1915.

I think we cannot run our state with only college professors and retired Californians. With increasing demands from all divisions of government our taxes are getting unbearable. The only way we can alleviate these taxes is to broaden our tax base and to do this we need industry.

I am for a clean environment but I think we have to clean it up with reason. We cannot put the country back in the shape it was in before the white man came unless we give the country back to the indians and move out.

If we take the stand that we will not export any goods or services from Montana that will cause some impact on our environment we are open to real reprisals. Minnesota could say no iron produced in Minnesota can go to Montana. Michigan could say, no cars produced in our state could go to Montana. Washington could say, no goods coming through our ports can go to Montana and no produce from Montana can go through our ports. Kind of foolish? What is the difference? Why should we refuse to export goods and services and expect other states to export to us?

Please leave politics and hysteria out of your decisions and work for a better Montana.

Yours sincerely,
R. J. Sterling

Helena, Montana 59601

Gentlemen:

With reference to the Editorial on the front page of the Billings Gazette, I for one, am getting just a little tired of reading about how much damage the Montana Power Co., Decker Coal Co., and all others are doing by strip mining in our state. And how much pollution there will be if we let the Montana Power Co. build this big plant.

The people in the State of Montana want our people to stay and work in Montana, yet they don't want to create any jobs for them. Just how do you expect to create jobs if you try to stop every kind of industry from coming into our state.

And another thing, where do you think you are going to get money from income taxes, if every one leaves our state to find employment. And they are doing it every day. There are not enough jobs for the people now. I have two children that have been trying to find work, with no luck.

I have visited the Colstrip area, and I can not see where the strip mining is doing as much damage as some of these stupid, and I do mean stupid environmentalists claim.

If I were the Montana Power Co., I would shut off the power for the whole state for about three days, and then we would see how fast people would be complaining about not having heat, electric lights, and able to use their electric appliances. I for one, like my electric appliances, and especially my electric automatic washing machine. I do not want to go back to washing my clothes on the board, of which I have done quite a few times in the past. I don't want to cook with wood or coal. You think there is pollution now, just what would it be, if all of us had to go back to cooking with the old coal range and coal heating.

Sincerely,

Norene Sellers

Re: Construction of coal-burning electrical generating plants-Colstrip area

Gentlemen:

I am writing this letter because I am extremely concerned about the unbelievably adverse criticism towards the plans by Montana Power Company and Puget Sound Electric to build certain electric generating plants in the Colstrip area.

First of all, I would certainly suggest that you disregard to a great extent the paranoid approach of the Billings Gazette to this problem. The Gazette, in its desire to make news, has consistently refused to present both sides of the picture; and consequently many of us in Billings feel that they are completely abdicating their responsibility as a news reporting service.

However, I, like all interested Montanans, am concerned with the plans of the two power companies to build a steam generating plant. Let me say that I am not in favor of total degredation of the Colstrip area. However, I must further add that I do believe that the plants can be built within the parameters as set forth by the State Department of Health, by the Environmental Protection Agency, and by all other associated state and federal bureaus who have jurisdiction over this type of operation.

There is, without a doubt, a vital need for the energy which can be produced from the low-sulfur coal currently found in the Colstrip area. Regardless of what politicians may say, there is now an immediate energy crisis, as witnessed by the fact that commencing as early as last winter, certain industrial plants in the Middle West and East were placed on an "interruptable" schedule and some were even shut down because of insufficient fuel, generally in this instance being natural gas.

Exhibit 4

All forms of energy are needed to make our country grow to maintain a viable economy. The American people have become accustomed to a relatively easy standard of living and are using increasing amounts of energy at a very rapid pace. It is going to be necessary that some type of plants be built in this area to generate needed electrical power throughout the United States. The coal in Eastern Montana does not necessarily belong just to us Montanans. The current study being carried on in the Decker-Birney area of approximately 900,000 acres discloses that approximately 80 to 85 per cent of the coal rights in this area are owned by the United States Government. Certainly the State of Montana does not have the power to prohibit the federal government from mining its own coal; and I think that the State should be extremely careful in any laws and regulations which it passes regarding the prohibition of strip mining and its associated activities.

However, I would like to add my voice to the few which I am sure you have received relating to the problem of the construction of the plants as discussed above. I am in favor of the project, but only so long as the plants are built within the regulations and restrictions as set down by the pertinent governmental agencies.

Very truly yours,

David Schaenen

David Schaenen

Exhibit 4

United States Department of the Interior

OFFICE OF THE SECRETARY
WASHINGTON, D.C. 20240

1973
ENVIRONMENTAL SCIENCES
DIVISION

ER-72/1344

FEB 26 1973

Dear Mr. Holtz:

This is in further response to your letter of October 20, 1972, asking for our comments on the Montana State Department of Health and Environmental Sciences' draft environmental impact statement, dated October 1972, on environmental consideration for Colstrip Power Plant, Rosebud County, Montana.

We regret that we were unable to respond to your request for comments within your timeframe due partially to the limited number of copies received with your letter of October 20. To facilitate more comprehensive reviews in the future, we should receive 20 copies of the documents at least 45 days in advance of the review deadline.

General

We find that the statement provides a good overall view of the environmental impacts of the construction and operation of the proposed project. The section on the Relationship Between Local Short-Term Uses of Man's Environment and Long-Term Effects is a typical example of the sound philosophical discussion woven throughout the statement. However, the statement is grossly lacking in quantification of the impacts.

We suggest that the construction permit include environmental protection provisions. We have enclosed a conformed copy of the Bureau of Reclamation's Huntington Canyon Water Service Contract and the Bureau of Land Management's transmission line right-of-way permit for the Jim Bridger Plant as examples of provisions which could be used with this project.

Figure 1 is referred to on page 4. The flow diagram following page 5 should be labeled "Figure 1." Likewise, the maps of sampling stations in the appendix should be designated Figures 2 and 3, as mentioned on page 19.

Exhibit 4

A portion of the statement is based on material prepared by the applicant. The appendix should include references to such material by title and date as well as references to other sources of data. Our other detailed comments are presented in the following paragraphs according to the format of the statement or according to specific subjects.

Department of the Interior's Jurisdictional Areas

It appears that the transmission line rights-of-way will cross the Crow Indian Reservation and possibly Northern Cheyenne Reservation. Three 230KV transmission lines are proposed, each in a corridor from near Hardin to Billings, Montana. If any element of the total project, including the water pipeline from the Yellowstone River, the transmission lines, or the strip mines, affects public lands or Indian reservations, the statement should clearly point this out on a map and in the text. It should also discuss any permits that are required for these facilities.

Northern Great Plains Resource Program

The proposed powerplant lies within the Northern Great Plains area. This area consists of large segments of Montana, Wyoming, North Dakota, and South Dakota which have vast amounts of relatively low sulfur coal and lignite. Extensive interest has developed in the Northern Great Plains' coal resources as the result of national energy needs and increased emphasis on improved air quality. The possibility of substantial development of these coal reserves has resulted in national, regional, and local concern for effective land use and resource utilization, including environmental resources such as mined area reclamation, optimum use of water resources, effects on plant and animal life, and economics.

Private, local, State, and Federal agencies are presently involved in the Northern Great Plains Resource Program. The State of Montana is an active participant. The program objective is to provide an analytical and informative framework for policy and planning decisions and alternatives. We suggest that this study be described in the final environmental statement along with a discussion of the proposed project's conformity to any present or future guidelines.

Exhibit 4

Maps

The statement should contain a map showing the general layout of the plant facilities, including the ash slurry ponds and the coal fields. This map should also indicate present and future use of land areas within the project boundary, including the transmission lines. A second map should also be included to indicate the existing and expected land uses of the region expected to be impacted upon by the project. These maps would be valuable assets to the final statement in the identification and quantification of expected environmental impacts.

Ash Disposal

A large amount of ash will be produced by plant operations in the 30-year projected life of the project. There is an inadequate description of the impact which the ash that is subject to erosive forces will have on the environment in the downstream and downwind area. It is stated on page 2 of the statement that periodically the ash in the ponds will be removed and used as fill in worked-out strip mines. It may be necessary to bury the ash in the stripped mines areas to prevent it from being moved by wind and water rather than simply using it as fill.

Programs to monitor the quality of surface and subsurface discharge from ash disposal areas and settling ponds should be considered in the section on Emission Control and Guarantees.

Pipeline and Water Supply

This section should provide a better description of the facilities in order that the environmental impacts can be adequately evaluated. Data on type of diversion facilities, pumping requirements, duration of construction period, and right-of-way should be given.

Transmission Lines

There is little discussion of the transmission line plan except for one paragraph describing three 230 kilovolt lines that will extend from the plant to the Billings area. In recent power system studies, the Montana Power Company has shown additional 230 kilovolt lines from Billings to Great Falls and Anaconda, Montana.

Exhibit 4

A high voltage transmission line map showing routing of all existing lines and the proposed and alternative transmission lines associated with the Colstrip Plant would be desirable and helpful in evaluating environmental impact. It should indicate the number of miles of new high voltage transmission lines that are involved.

Geology and Hydrology

This project includes a long-term strip mining operation resulting in considerable disturbance of the bedrock, soils, and topography. The geology and soils of the area and the impact of geologic conditions on all facilities and operations should be discussed in considerable detail in the statement. Much of this data could be provided in illustrative materials and maps. Since the geology and hydrology associated with the project are not adequately described, the impacts of the facilities and operations on the water resources cannot be evaluated.

Strip Mines

Reclamation of the strip mine area should be discussed. The mining operations will result in considerable changes in the soil. This significant change in addition to being located in a semi-arid climate may present problems in reestablishing a suitable vegetation cover to stabilize soil and slopes. The intent and plans of the utility in regard to the mined areas, standards that apply to strip mining, and monitoring programs should be covered in the statement even though, as indicated on page 3, a separate environmental impact statement will be written on strip mining and necessary reclamation.

Detailed Description of Process

The third sentence on page 5 is incorrect. The reaction of calcium carbonate and SO_2 will not result in a solid sodium salt.

We have serious reservations at this time concerning the implication of the last sentence, first paragraph, page 5. Although great strides have been made in the development of SO_2 removal processes, our latest review of the situation indicated that none of the many different systems being studied have as yet been commercially demonstrated (continuously operated for more than 1 year on a scale of 100MW or larger)

Exhibit 4

in the United States. Operation of the 22 full-size desulfurization control processes for powerplants, which are in the design, construction, or startup phase in this Country has been intermittant and serious plugging, scaling, and corrosion problems have been reported. Under such circumstances, it is doubtful that any SO_2 control process is yet available whose operability can be guaranteed at any level.

Population

The population of Lame Deer consist of 1,341 Northern Cheyenne tribal members and about 2,000 non-Indians. The second paragraph on page 7 should be corrected to indicate this data.

The "Tongue River Indian Reservation" should be changed to "Northern Cheyenne Indian Reservation."

Meteorology

We suggest that the amount and distribution of precipitation be added to this section on page 8.

Recreation

The excellent recreational opportunities in Southeastern Montana is recognized on page 8; however, neither this section nor the following impact section discusses the cumulative impact of the construction and operation of this plant and future coal-fired plants in the area. A plant-by-plant analysis will not reveal the impact that all of the plants will have on the nearly pristine environment of eastern Montana. Therefore, it is necessary to consider the present proposal in relationship to future developments in order to obtain an accurate assessment of these impacts.

Sulfur Oxides

The comments given for the foregoing section on Description of Process also apply to this section beginning on page 14.

Trace Elements

The purpose of the last sentence, paragraph 4, page 18, is not clear. This paragraph should relate the concentrations of mercury indicated to acceptable or safe emission levels. If

Exhibit 4

the venturi scrubber will be used to remove mercury vapor, it should be indicated.

Emission Control and Guarantees

Although the procedures to eliminate problems with scrubbers described on page 23 are reasonable from a technical standpoint, the draft statement does not indicate its economic implications. Costs for currently tested SO_2 control systems are $40-$70 per kilowatt plus rather high operating costs. The procedure of reducing the boiler load everytime one of the scrubbers is shutdown for cleaning purposes would significantly increase the operating cost and could interfere with the noninterruptible nature of the power by lowering the reliability of the power generation.

Plans by Applicant to Maintain Air Quality and Lessen Overall Impacts

According to the list of studies underway and the company's environmental policy given on pages 24 and 25, a significant effort is being made to evaluate and control the impacts of the construction and operation of the plant. It appears that if the information gained from these studies would be incorporated into the final environmental statement that many of our concerns for adequate quantification and description of impacts would be satisfied.

A typical example involves historical values. An indication of the historical value is given on page 8; however, it is also stated that the archeology of the area is not well known. It is stated on page 24 that the University of Montana has an archeological survey underway for the plant site. The available information from this study should be reflected in the section on page 8.

Land Use

The general description of the changes in land use is not adequate. According to page 27, the plant will occupy 1,365 acres, the mine will disturb an area of approximately 2,000 acres, and the aqueduct and transmission line will alter approximately 2,900 acres. This significant change in land use should be quantified. The statement should indicate the amount of land transferred to or from crops, forest, recreation, and wildlife. It should indicate the intensity of use and probable use if the project were not built.

Exhibit 4

Water Use

The impact of withdrawing up to 8,000gpm of water from the Yellowstone River is not discussed except to indicate on page 29 that aquatic ecosystems will be altered in a number of ways. It appears that these effects will be negligible; however, data should be included to indicate to the reviewer a basis for judging the magnitude of the diversion in relation to historic flows. Also, since there is a possibility that the proposed diversion will interfere with prior water rights, we think that a discussion of augmenting natural flows during dry periods from Mystic Lake Reservoir should be included.

We suggest that the final statement consider the need for irrigation and the possibility of using sewage plant output in revegetation programs.

Impact on the Community During Construction

It is mentioned on page 32 that haphazard trailer parks and temporary unplanned residential and commercial development could negatively affect air and water quality, aesthetics, and economic and social parameters. This statement is so general that it could be used in any report; however, its value is negligible. This section should indicate the impacts which are expected to occur as a result of the project. General statements are of little value in impact assessment.

Another example of such a general statement is item 6 on page iii. This sentence says that the long-term adverse effects may well outweigh the short-term gains. The writer could just as appropriately have said that the short-term gains may well outweigh the long-term adverse effects. This type of assessment is of little value to the reviewer or the decisionmaker.

Adverse Environmental Effects Which Cannot be Avoided Should the Proposal be Implemented

Several of the items listed in this section appear to be beneficial environmental effects. The environmental statement can be equally misleading by being too conservative as it can by being too liberal in its assessment of adverse impacts.

Exhibit 4

Alternatives to the Proposed Action

Many general statements are made in the document that need to be expanded and supported with factural information. For example, it is stated on page 35 in paragraph E that feasibility studies indicate that hydroelectric power could not supply the needed electricity. If such studies are a matter of public record or available for review, the statement should indicate this.

A factural discussion is also needed on the environmental problem and negative aspects mentioned in the first paragraph on page 35.

This section should evaluate the environmental impacts of the proposed action in addition to evaluating the economics. It is not necessary to describe these impacts to the same depth that is done for the proposal; however, there should be a general assessment which could be in the form of a comparison of impacts between the proposal and the alternatives.

Irreversible and Irretrievable Commitments of Natural and Economic Resources

A general statement is made in the second paragraph on page 41 that if adequate reclamation is not practiced, the 2,000 acres of land will be permanently degraded. This statement does not indicate whether adequate reclamation will be practiced. At a minimum, the paragraph should indicate the degradation which will remain after programs are completed.

We hope these comments will be useful in the preparation of the final environmental statement.

Sincerely yours,

Assistant Secretary of the Interior

Mr. Don Holtz, Chief
Air Quality Bureau
Environmental Sciences Division
State Department of Health and
Environmental Sciences

Enclosures

Exhibit 4

Testimony
Miles City Hearing
January 5, 1973
Department of Health and Environmental Sciences
Subject: Draft: Environmental Impact Statement on the Proposed Montana Power Company Electrical Generating Plant at Colstrip, Montana October 1972

This impact statement, which is the subject of this hearing, was prepared as a result of the directives contained in the Montana Environmental Policy Act. The Clean Air Act of Montana which regulates air pollutant emissions in this state was passed in 1967; by the later passed Montana Environmental Policy Act, some of the purposes and considerations, as well as the procedures, of the Clean Air Act of Montana were in effect amended and broadened. See Section 69-6507 R. C. M., 1947. The Montana Environmental Policy Act, hereinafter referred to as "MEPA", in its "Declaration of Policy for the Environment" lays down some goals for the administration of the laws of the State of Montana, two of which I particularly wish to call to your attention. They are as follow:

> to . . . fulfill the responsibilities of each generation as trustee of the environment for succeeding generations;
>
> and
>
> to . . . attain the widest range of beneficial uses of the environment without degradation, risk to health or safety, or other undesirable and unintended consequences;

I wish to emphasize the concept of use without degradation and use without other undesirable and unintended consequences. I find throughout the statement areas where there is such a lack of information that the consequences of the action could certainly be undesirable and unintended.

MEPA directs that an impact statement shall be prepared using an interdisciplinary approach utilizing the natural sciences, social sciences, and environmental design arts, and that prior to making the

Exhibit 4

statement, the responsible state official, i. e. someone in the Department of Health and Environmental Sciences, shall consult with and obtain the comments of any state agency which has legal jurisdiction or expertise in any environmental impacts involved in the action being considered for the statement. Looking over the list of authors of the draft statement and their qualifications, it would seem that the weight of the expertise involved is heavy in the area of air pollution control, but rather light in other areas of the natural sciences, thin in the area of the "environmental design arts", and non-existant in the areas of the social sciences. There is no indication in the statement that consultation took place with other state agencies as directed by MEPA.

The atmosphere of the statement reflects a rather passive attitude on behalf of the department, a waiting by the department for the permit applicant to furnish hard information upon which the department can base its opinions. My reading of MEPA does not indicate that the role of the department preparing an impact statement is to sit back and wait until the permit applicant furnishes information from which the department can prepare a statement. The impact statement should be an independently prepared document and should indicate some initiative on the part of the agency preparing the document. The statement gives off an aura of insufficient preparation, as though the authors were greatly hurried and may not have had time to sufficiently investigate the situation and obtain source material and documentation. One outside source is cited twice as a reference in the entire document. The statement would be more persuasive and a stronger document, if the sources supporting the authors' opinions were cited with footnotes and bibliography.

Exhibit 4

The plans and specifications for the air pollution control equipment are very general in the statement, so general in fact, that it is difficult for an expert to make a real assessment of its effectiveness, let alone a struggling member of the public like myself. The regulations of the State Board of Health relating to air pollution control equipment, Regulation No. 90-001, III allow the director to dispense with the requirement that plans and specifications be submitted with the application upon prior written agreement. The technical information on the venturi-type scrubbers to be employed is so general that I wonder if a prior written agreement exists as allowed in the regulations. The name of the contract-bidder does not appear in the statement, which might raise still another question, and that is whether or not the permit applicant has let the bid for the construction of the scrubbers.

It would have been enlightening to have included in the statement the experiences of the Arizona Public Service Company with the wet scrubbers on Units 1-3 of the Four Corners plant and to have also set forth the experience of Kansas Power and Light with using wet scrubbers to control both particulate matter and SO_2, with the SO_2 control up to a factor of 70% efficient (The Price of Power: Electric Utilities and the Environment, by Komanoff, Miller, and Noyes, published by The Council on Economic Priorities, pp. 17 and 22). It would be useful to have a history of the reliability of venturi-type scrubbers showing in which areas scrubbers of that type are prone to mechanical troubles impairing their efficiency together with a setting forth of the means by which the design specifications of these particular scrubbers will overcome such problems, and if it is the opinion of the department engineers,

Exhibit 4

both chemical and mechanical, that such problems can be overcome. The efficiencies of the scrubbers depend on the factors of the speed of the flue gases taken together with the size of the solution droplets from the atomizer. In 1968 these matters were somewhat a matter for mathematical calculation rather than practical experience. (Air Pollution, Vol. III, Stern(Editor), Chp. 46, Source Control by Liquid Scrubbing by Seymour Calvert, Academe Press, New York (1968)). Evidence should be advanced in the statement indicating that theory has advanced into effective reality. On page 5 of the statement we are told that there are guarantees on the emission control system. Who is the guarantor, and does the department adjudge the material which forms the basis of the guarantee to be effectively convincing.

Various places in the statement ponds for the disposal of fly ash and the effluent for blow-down and from the scrubbers are mentioned. If the applicant uses soda ash in the scrubber, because sodium is a component, the solutions which will form as a result of its reaction with the flue gases will have a sodium component, and therefore tend to be soluble in water. If there is deposit of this material in fly ash ponds, which will be kept wet to keep down the dust problem, a question arises in my mind as to how much of these sodium compounds would leach out of an unsealed pond and find their way into the ground-water table, increasing its salt content. Calcium compounds are relatively insoluble in water, and would probably have no effect.

Another point in relation to the fly ash ponds is their location. The statement does not set forth an analysis of the chemical composition of the flyash from the Rosebud seam, therefore, it is an unknown factor

other than reference in the statement that it will have an overall alkaline character. It is not stated if the ponds in which the fly ash will be deposited will be sealed to keep the mineral content from leaching out into the underground water supply. It would seem that the Korette plant in Billings would have an adequate ash supply from which to obtain an analysis. An alternative plan to sealing the pond with a commercially prepared sealer such as concrete, might be to level and excavate in the old Burlington Northern spoils in the Colstrip area in the spoils areas which are largely composed of gray and blue shale material. These shales have a low permeability to moistureand would probably be nearly as effective as concrete in preventing unwanted mineral leaching.

A certain lack of candour must be imputed to the applicant when one compares the information submitted by the applicant to the Department and information filed elsewhere by the applicant. The statement says that a 24 inch stainless steel pipeline will be used to transport water from the Yellowstone River to the plant, which will be sufficient to serve a 700 MW plant, but in the Rosebud County Court House, the applicant filed a water appropriation for a 60 inch diversion pipe. A 60 inch pipe takes a much bigger hole and results in much more disturbance of the land than a 24 inch pipe. Just the land reclamation problems would be much more severe, because in areas of thin soil, it would take a great deal more blasting of subsurface rock to bury a 60 inch pipe than it would a 24 inch pipe. The question arises as to what are the applicant's intentions with the excess water.

Exhibit 4

The applicant's intentions are important, because this statement does not consider the additive effects of additional plants. One wonders if the applicant does indeed have plans for additional plants, when the applicant is so long-headed as to appropriate a great deal more water than is required to operate a plant of this size.

An additional area indicating lack of candour is the incomplete information supplied regarding all the new construction of transmission lines in connection with this plant. The statement gives the impression that all new construction will cease at Billings. The applicant did not supply the information that it was involved with Bonneville Power Administration seeking power line routings over the Continental Divide to the Lewiston, Idaho area through Federal lands. This is an additional environmental impact which the applicant apparently chose to withhold from the Department.

There may be some question whether the applicant can clearly appropriate the river water at this time. In 1969 the Montana Water Resources Board filed numerous documents in the Rosebud County Court House appropriating all the water in the Yellowstone River which was unappropriated by any other appropriator at that time. The applicant filed its notice of appropriation in December 1970. The applicant may be unable to begin appropriation steps until the claim of an agency of the State of Montana to the water has expired.

If the applicant proposes to use wooden poles for its high voltage transmission lines, it should be specified that they be proof against the effects of grass and timber fires in the areas through which they pass.

The statement is silent on the nature and chemical analysis of the water from the Yellowstone River which the applicant proposes to use in its plant. If the water from the River is "hard" water, then the applicant will have to soften the water to prevent excessive scale accumulation and increased maintenance costs. If the water must be softened, there are different methods, some of which have undesirable side by-products. Some processes of softening water increase the salt content of the water. This water, if discharged into unsealed ash pond, may in some cases increase the sodium content of soils already sodic. This area should also be examined in the statement.

On page 3 of the statement it is noted that the plant will have a coal storage area, but it is not stated in the statement what proposals have been made to control the dust from the coal storage area and its attendant activities. It should be noted that a strip mine in the Rock Springs, Wyoming area was forced to close because it could not economically control the dust from its operation and storage area in a manner which could meet the National Environmental Policy Act Standards.

It will be interesting to see what effect the large amounts of steam condensation the wet cooling towers will release will have on the area surrounding the plant. It has been found in the Appalachian region that small fogs and icing may be created 1/4 mile away from the plant. (The Price of Power, op. cit. p. 57) It should be noted that the excavation and cement work for the generators of the plant at Colstrip are situate quite close to the paved state highway. It might be possible that wet cooling towers on the plant could increase the accident rate on this road during the winter months. There is nothing in the impact statement indicating the location of the cooling towers in relation to the

Exhibit 4

state highway. Another question arises in my mind. The new Montana Constitution allows suit against the State. If an accident happened upon the state highway as a result of icing conditions directly attributable to the wet cooling towers excessive production of atmospheric moisture, under the provisions of the New Constitution, would the state be liable for having issued a permit which allowed the construction of such a device in an area where its emissions could constitute a hazard to highway traffic?

There are presently suits pending dealing with the interpretation of the clause in the National Environmental Policy Act relating to the anti-degradation phase of that act. MEPA was modeled after the national act according to MEPA's author, George Darrow. Air sampling has been done in the general Colstrip area. Maps are included in the statement indicating approximately where the samples were taken. I find the information relating to the sample locations quite incomplete. Judging from the map, they were all quite close to a road of some kind. There is no information given concerning elevation, approximate distance from the road, general topography (whether on top of a hill or down in a draw), frequency of traffic on the road, whether the sampler was in someone's yard, by a windmill, or in the middle of the prairie. If the intention was to measure the air quality in areas close to human activity only, it should have been clearly stated in the statement. In addition to traffic on unpaved roads, the wind will some times go down the road stirring up as much dust as a car, but no, or very little dust, will be blowing across the prairie at the same time. I do not think as the samples were taken, judging from the statement, that the Department has informed itself of the quality of the Colstrip area ambient air prior to the operation of the

proposed plant.

It is difficult to believe the statement of page 18, "Thorough, comprehensive sampling for trace elements has not been done on this coal." It seems that surely with all that has been burned at the Korette plant and all that is being shipped East to be burned in Illinois, that someone has not gotten curious about what is in this coal beside carbon and a low rate of sulphur.

Dr. Clarence C. Gordon on December 14, 1972, in sworn testimony stated that he received four samples of coal from the State Department of Health and Environmental Sciences, which that department alleged to be from Colstrip, and that he tested the four samples for flourine content, and found that the F content ranged from 40 ppm to 80 ppm. Dr. Gordon forwarded the samples on to an unnamed laboratory in Seattle, and their analysis concurred with his and not with the information presented in the statement. Assuming 40 ppm (see p. 18, statement) in relation to the 4.2 ppm used as average in the statement to arrive at the 77 lbs. F projected to be released per day, then there is a possibility that rather than releasing 77 lbs. per day, a more nearly correct figure is 770 pounds of F released per day from the plant operations. If the flouride factor is greater than 40 ppm, then it is possible that this plant will be approaching or exceed the 864 pound per day hopeful emission standard set for the Columbia Falls aluminum plant.

On page 19, the following statement appears: "However, it is expected that a large but unknown percentage of the flourides will be removed by the venturi scrubber." This X factor becomes extremely frightening if the amount of flouride to be released is 10 times the

Exhibit 4

amount anticipated in the statement. Dr. Gordon also stated that flouride pollution had been detected as far as 6 miles away from the Korette plant in Billings. The reason he stopped with six miles was that his study had tested no further away, which did not mean that the pollution did not exist beyond that point. Pines are exceptionally sensitive to elevated flouride levels. For more information on this point, see Dr. Gordon's study of the affects of flouride emissions in the Columbia Falls area.

In Barry Commoner's book, The Closing Circle (Bantam Books), p. 69, reference to a study is made which studied the relation of NO_2 and tomato plant growth. A dosage of 1ppm reduced plant growth 30%. It brings to mind the question, if prolonged periods of NO_2 emissions, although at prescribed dosages, would significantly reduce the amount of grass cover produced on surrounding lands.

The statement is entirely silent on the possibility of the production of photochemical oxidants as a result of hot weather in the Colstrip area and the plant emissions.

There is a reference in the statement to the "Colstrip airshed". It seems to be in reference to how far the wind will carry the plant emissions before the emissions will become so dispersed that no one will notice them. I think it would be very informative for the public to know how many miles in each direction the Colstrip airshed extends. This would serve to define the area which could expect to have its air somewhat degraded and would give a clearer idea of the impact of the plant.

The statement indicates that most of the SO_2 will drop out of the "clean" stack gases within 1/4 mile from the stacks. Will this SO_2 affect any reclamation experiments currently being carried on by MSU?

Exhibit 4

There is no information in the statement which would tend to predict the number of days which would have winds over 20 miles per hour, thus causing a different pattern of dispersion of plant emissions and varying from the dispersion pattern of days which would be only moderately windy or still. It might be possible that given the prevailing winds in the area to have a long narrow path of relatively intense effects from the emissions if the prevailing winds are strong enough often enough. (See Whatever Happened to Fresh Air, by Michael Treshou, University of Utah Press, Salt Lake City, 1971, p. 46 et seq.)

Mr. Treshou also has some interesting comments on fine particulate matter or aerosols. His opinion is that tall stacks, wind and diffusion do not remove the polluting emissions, but only disperse, and that particles smaller than 10μ remain suspended almost indefinitely and that those smaller than 0.1μ remain suspended until they find an agent with which they can chemically react. SO_2 and F form solutions in rain and snow and fall as precipitation. On page 51, he states, "In regions where precipitation is sparse, the pollutants may be longer lived." (Treshou, op. cit.) The statement does not effectively discuss the life of the pollutants or give any idea as to where they may ultimately accumulate. The build up of pollutants is obvious in the Billings area over the period of the last 20 years. They are now visible on any clear day hanging over the Yellowstone valley. I think the statement is defective in that no real effort is made to determine the ultimate natural barrier which will intercept the pollutants' natural drift on air currents.

In order to determine the effect which plant emissions will have on parties other than the applicant, whether the effect be on health, society, or economics, it would be worth while to set forth

how much land applicant owns and controls in the area, and how far the radius of applicant's land does extend from the proposed plant site. This would also give an indication of whether the effect from the plant emissions will be borne primarily by the applicant and its employees and subsidiaries, or by other persons who would stand to receive no financial gain from the plant.

Actions by the applicant raise doubts in my mind as to the future plans of the applicant in construction of additional power plants. At present the applicant in the last year has mined 5 million plus tons of coal with an electric shovel having a 24 cubic yard bucket. It is proposed to feed this proposed plant 3 millions tons of coal yearly; therefore, it would seem reasonable that this plant would need a shovel no larger than the current shovel to supply its needs, if an additional shovel is needed. I wonder why then has the applicant sought bids for two electric shovels each having a bucket of 60 cubic yards in capacity, as stated in applicant's July 1972 shareholders' report.

Considering the amount of water sought by the applicant in December 1970, the ordering of two huge shovels presupposing a drastic increase in strip mining activity, it is reasonable to assume that the applicant has other big plans which may well cause additive effects in the Colstrip area and that applicant is probably well along in its progress in their execution.

The applicant has not entered into a tenancy in common agreement with Puget Sound Power and Light (See "Abstract of Agreement", dated October 27, 1972, executed by and between Montana Power Company and Puget Sound Power and Light Company, filed October 31, 1972 at 3:20

P. M. in Book 21, Page 168, in the office of the Clerk and Recorder of Rosebud County at Forsyth, Montana) for the purpose of receiving free financing from Puget Sound Power and Light Company. Apparently the applicant would have use believe that the people of the State of Montana will receive all the power produced from this proposed plant, but I hardly find it creditable that Puget Sound Power and Light would be so generous as to put up money for plant construction, receiving nothing in return. The applicant should have divulged exactly how much benefit the citizens of Montana will actually receive from the plant. Several areas come to mind. How many Montanans will be employed in construction and operation of the plant? How many Montana firms will have contracts to supply the needs of the plant and participate in its construction? How much of the power produced from this plant will be used in Montana for the next 5 to 10 years after the plant begins operation? In light of the ecological areas about which so little appears to be known, factors such as the foregoing would have to be disclosed in order to give any balance at all in favor of the construction of the plant.

There are so many factors on which the statement fails to shed any light. Some of the information may be known only to the applicant and has not been disclosed to the Department. Some of the research information the Department was probably hindered in obtaining through lack of time and funds. With the information set forth in the statement at this point, I think that the opinion that the long-term detriment resulting from the construction of the plant would out weigh its short-term benefits is correct.

Exhibit 4

I, therefore, commend to the Board and to the Department for their mutual consideration, the following language from the Board's publication entitled "Implementation Plan for Control of Air Pollution in Montana", Section III. Control Strategy, Sub-section C. Non-degradation Clause.:

> The following non-degradation clause is to be made a part of this plan under the authority and requirements of the Federal Register, dated April 30, 1971, Section 410.2. c as follows: "The promulgation of national primary and secondary ambient air quality standards shall not be considered in any manner to allow significant deterioration of existing air quality in any portion of the state." In compliance with this directive and as a policy of the State Board of Health of Montana it is hereby declared to be the policy that ambient air whose existing quality is better than the established standards, will be maintained at that high quality unless it has been affirmatively demonstrated to the Department of Health and Environmental Sciences of the State of Montana that a change is justifiable as a result of necessary economic and social development vital to the state. Any industrial, public or private projects or development which would constitute a new source of pollution or increased source of pollution to high quality air will be required to supply the necessary degree of treatment to maintain that high quality of air.

The statement which sets forth the standards and operating performance for the emission control equipment is so indefinite that considered in relation to the foregoing requirement, I do not think anyone can be sure that the applicant can meet the required standard to maintain the Colstrip ambient air quality. I would remind the Board and the Department that such control of emission must be <u>affirmatively demonstrated</u>. I do not think this has been accomplished, and that therefore, the permit should be denied at this time.

Submitted by:

E. P. Withers
Chairman, Northern Plains Resource Council

Exhibit 4

ORAL TESTIMONY PRESENTED BY PATRICK SWEENEY AS TRANSCRIBED FROM TAPE RECORDING MACHINE

Ladies and Gentlemen. My name is Patrick Sweeney. I am a native of Montana, from Billings, and a member of the Northern Plains Resource Council. I am a graduate of the University of Montana, Missoula, and am not part of that some percent of young people who wish to leave Montana for employment elsewhere. Instead, I wish to stay in Montana. I plan to stay in the Montana I grew up in. I am not an emotional environmentalist just to mumify Montana and let her die in stagnating economy. I do not wish to turn back the hands of the clock. I'm concerned about people, however, and that's what has led me to Miles City today. I would like to address my comments to one aspect of the draft environmental impact statement--the standards for granting of the Montana Power application.

As stated in the Implementation Plan for Control of Air Pollution in Montana, prepared by the Montana State Department of Health and Environmental Sciences, Division of Environmental Sciences, Bureau of Air Quality, the section entitled 'Standards for Granting Applications, Section A. "The Director shall deny a permit to construct if the applicant does not show that it may be expected to operate without emitting air contaminants in violation of standards and regulations formulated under authority of the Clean Air Act of Montana or will interfere with the attainment or maintenance of any application, applicable national standards, or violate any regulations promulgated by the Administrator, U. S. Environmental Protection Agency, pursuant to the Federal Clean Air Act as amended." Given these standards for granting or denial of the application, there is a non-degradation clause in the Implementation Plan for control of air pollution in Montana. I wish to quote that clause if I may. "The following non-degradation clause is to be made part of this plan under the authority and requirements of the Federal Register, dated April 30, 1971, Section 410 (2)(c) as follows: The promulgation of national primary

Exhibit 4

and secondary ambient air quality standards shall not be considered in any manner to allow significant deterioration of existing air quality in any portion of the state. In compliance with this directive and as a policy of the State Board of Health of Montana, it is hereby declared to be the policy that ambient air, whose existing quality is better than the established standard, will be maintained at that high quality unless it has been affirmatively demonstrated to the Department of Health and Environmental Sciences and the State of Montana that a change is justifiable as a result of necessary economic and social development vital to the State. Any industrial, public or private projects or development which would constitute a source of pollution or increase a source of pollution to high quality air would be required to comply to necessary degree of treatment to maintain that high quality of air."

Unfortunately, the Department of Health and Environmental Sciences has not addressed itself in any manner in the draft environmental impact statement to the non-degradation clause. I believe that it is important to the Colstrip development because the high quality air in the Colstrip area will be significantly degraded by 700 megawatt coal-fired electrical generating facilities and that the presently proposed pollution abatement equipment for these plants will not "supply the necessary degree of treatment to maintain that high quality of air;" instead, it will significantly deteriorate the air quality. The significant deterioration of existing high quality air by industrial development is now being litigated in federal court. A federal appeals court has already affirmed a lower court decision that EPA was wrong in interpreting the Clean Air Law in such a way as to permit deterioration of existing air quality. Air quality standards or non-degradation standards would apply to relatively clean air with pollution levels below secondary limits established by the federal government. This would most certainly include the Colstrip area. The court decision, in fact, is aimed at areas where any of the six air pollutants,

Exhibit 4

including sulfur dioxide and particulate matter, currently are below the secondary limits. Thus, a coal-fired power plant planned for the Colstrip area, where the air is relatively pristine at present, must be barred altogether because the best available controls cannot adequately control its pollutants. It has been asserted that prohibitions against air quality deteriorations would be tantamount to barring all industrial and population growth in rural areas. However, in specifying significant deterioration of existing air quality, the courts have left EPA and the state's administrative latitude. That is to say, if there are several proposals that the federal agency might allow levels of five major pollutants, particulates, sulfur dioxide, nitrogen oxide, hydrocarbons, and photochemical oxidants to rise by 10 percent or 5 micrograms per cubic meter, whatever is greater, from existing levels, thus giving some latitude for development of rural areas with high air quality. This would allow for some development, but the level of air quality deterioration would not be such that the high quality air in areas such as Colstrip would be deteriorated to the level of the air quality of Los Angeles or New York City. In a June opinion by the U. S. District Court, Judge John H. Pratt concluded that "Permitting the states to submit plans which allow pollution levels of clean air to rise to the secondary standard levels of pollution is contrary to the legislative policy" of the Clean Air Act. In addition, "the public interest in this case strongly supports legislative policy of clean air and non-degradation of areas in which the clean air exists." Thus, it can be concluded that given the implementation plan for control of air pollution in Montana, the Department of Health and Environmental Sciences has the authority to deny the Montana Power Company's permit to construct the 700 megawatt coal-fired electrical generating facility at Colstrip, Montana, due to violations of the non-degradation clause; that is, the air pollution abatement equipment to be installed at the Colstrip plant will significantly degrade existing ambient air quality whose standards are higher than secondary ambient air

Exhibit 4

quality standards of the federal government. On these grounds, the permit for construction must be denied.

I would submit for the record of this hearing the following petition to the Department of Health and Environmental Sciences and its some 1,000 odd signatures. The petition reads as follows:

"WHEREAS, the State of Montana has adopted as part of its air pollution control regulations, the following statement, the promulgation of national primary and secondary ambient air quality standards shall not be considered in any manner to allow significant deterioration of existing air quality in any portion of the state. In compliance with that Federal directive, the State Board of Health has adopted a directive and policy that ambient air whose quality is better than the standards will be maintained at that high quality unless it has been affirmatively demonstrated that a change is justifiable as a result of "...necessary economic and social development vital to the State." WHEREAS, it is the opinion of the undersigned that the environmental impact of the proposed Colstrip generating plant does not meet the foregoing requirements, and that it would substantially degrade the quality of the ambient air in the Colstrip area, and that it has not been demonstrated that the construction of the plant would provide economic and social development vital to the State of Montana, and that it is probable that such a plant, being the first of a series would create more social and economic problems than it would solve: THEREFORE, it is the opinion of the undersigned that the State Board of Health would deny the permit to construct to Montana Power Company for the construction of a coal-fired electrical generating plant at Colstrip, Montana.

Thank you.

& Environmental Sciences
State of Montana
Helena, Montana 59601

Dear Mr. Vichorek:

Responding to the question in your February 20 letter, the power output of Libby Dam is included in forecasts of resources available to meet projected power requirements in the Pacific Northwest, which will help alleviate power shortages in Montana.

The electrical loads which the regional cooperative Hydro-Thermal Power Program is attempting to supply includes essentially all loads in Idaho, Washington, Oregon, and Western Montana with the exception of those served by Idaho Power Company, Montana Power Company, and Utah Power and Light Company. Even though the planning is done on a regional basis, the addition of Libby will not change the fact that BPA will be bringing energy into Montana to meet its obligations. Item 10 of my February 1 letter discusses this in some detail.

Obviously, it is not prudent for the entire output of a federal resource project such as Libby to be dedicated to a particular State. More efficient utilization is possible if the Project output is integrated with other projects to meet the needs of a larger coordinated system.

The average firm generating capability of Libby Dam under critical water conditions is 186,000 kilowatts (note the change from incorrect figure of 204,000 in my February 1 letter). January firm peaking capability associated with the first 420,000 kilowatts of installed capacity is 216,000 kilowatts.

Enclosed for your information is our recently-published "Power Outlook". Please let me know if you have additional questions.

Sincerely,

Ronald H. Wilkerson

Dept. of Health & Environmental Sciences
State of Montana
Helena, Montana 59601

Dear Mr. Vichorek:

I am pleased to respond to your 12 January letter in which you properly challenge the statement that "in general, the most rapidly growing utilities have the highest rate of return".

High rate of return is a result of indulgent regulation or non-regulation. The most convenient documentation of the non-correlation between growth and return is the attached table from the 1 January 1973 issue of Forbes.

You can there see that unregulated Texas utilities rank highest in profitability, followed by those in Ohio (the state with the ultra-lenient "reproduction cost new" rate base), Illinois (fair value rate base) and Minnesota (no regulation). By checking the growth column for these same utilities you will see that most of them are below average by that measurement.

By carbon of this letter, I am asking Professor John B. Dicks of the University of Tennessee to send you some of his materials on MHD development in other countries.

The Senate hearings you requested are being sent under separate cover. They are scarce documents, so I may refer others to you, or perhaps you could put them in a Helena library.

Very truly yours,

Lee Metcalf

Mr. Daniel Vichorek
Technical Writer
Department of Health and
Environmental Sciences
State of Montana
Helena, Montana 59601

Dear Mr. Vichorek:

I received a copy of a letter from Senator Metcalf to you dated the 18th of January 1973, along with a copy of your letter to him. Enclosed is an article of mine on the status of MHD power generation in the world that appeared in MECHANICAL ENGINEERING this past spring. Since this article was written, we have heard that the U-25 plant in Moscow has been operating with 5MW of MHD power. This indicates that they are on or ahead of schedule in bringing this technology into use in the Soviet Union. We have been trying to negotiate a program of technical cooperation in MHD with the Soviet Union and were having great success until the recent bombing of North Viet Nam brought a diplomatic coolness on their part in relations with the United States. Hopefully, with the cessation of hostilities in Viet Nam, we can resume negotiations again.

I have the responsibility of coordinating all of the energy programs in the University of Tennessee System and so have obtained some overview of the current energy situation. It appears that coal is the only resource that we have to rely on to fill the gap between the failure of the oil supply and the time near the end of the century when appreciable nuclear fuels can be produced in the breeder reactors.

Exhibit 4

Those of us in the energy field have long been grateful to Senator Metcalf for his intelligent efforts to lead the electrical utilities towards policies that are more nearly in the public interest than they are now. If we can send you further information on power generation, please let us know.

Sincerely,

John B. Dicks
Professor of Physics

Exhibit 4

The MONTANA POWER COMPANY

GENERAL OFFICES
ELECTRIC BUILDING
BUTTE, MONTANA 59701

December 29, 1972

Mr. Don Holtz
Chief, Air Quality Bureau
Department of Health and
Environmental Sciences
State of Montana
Helena, Montana 59601

Dear Mr. Holtz:

With reference to our past conversations, I would like to summarize the present status of The Montana Power Company's planned electric transmission and water system portions of the Colstrip project. That project as described in our application to your Department for a Construction Permit to install equipment which may contribute to air pollution and to install air pollution control equipment is two 350 MW generating units. With that generating capacity, the following facilities will be required:

Electric Transmission Lines

The partially completed Billings-Hardin-Colstrip 230 kV line will be completed. That line is presently completed from Billings to Hardin, and most of the right of way from Hardin to Colstrip has been secured. This line will be completed in 1973 and will be used to supply power to the Colstrip area until the Colstrip generation is on-line.

In addition to that line, two 230 kV lines from Colstrip to Billings will be required to bring the Colstrip generation into the existing MPCo system. Those lines will be required, one in 1975 and one in 1976. Their route has not yet been detailed, but presently it is assumed that generally they will be north of the Yellowstone River valley and will connect to MPCo's existing system at a new switchyard to be located north of Billings.

The existing MPCo electric transmission system is continually expanding to meet the increasing energy requirements of its customers. Generating capacity introduced into the system at Billings will change the system flow patterns and may change the timing of system additions. Such additions may be influenced by the Colstrip project, but are not an integral part of that project.

Exhibit 4

Water System

The proposed two 350 MW units will require approximately 8,000 acre-feet/year of water, at rates up to a maximum of 8,000 gpm. The water will come from the Yellowstone River at either Nichols or Forsyth, depending on the pipeline route selected. Two potential routes currently being evaluated are from Nichols up Armells Creek valley, and from Forsyth over the benchland between Armells and Rosebud valleys. The pipeline size will be in the range of 22" - 26" OD, depending on the length of the route selected.

The design of those particular facilities is still flexible, and of course, the best planning maintains the maximum flexibility for as long as possible. The greater the flexibility, the more options remain open so that the final plan will have been adjusted to accommodate the latest technology, including all environmental considerations.

Additional generating capacity at the Colstrip site is a potential change that would affect these facilities. There has been discussion and interest shown by utilities in the northwest for this additional generation. No commitments have been made but the discussions continue. If a commitment is made soon enough, significant economies could be realized by enlarging the initial water pipeline rather than having to install a second line which would also have great environmental advantages. The same would apply to the transmission lines.

Be assured that if changes materialize before a permit is granted, the Department of Health and Environmental Sciences will be notified immediately and a new application submitted for permission to construct any new equipment capable of emitting any contaminants to the atmosphere.

Sincerely,

Carl R. Anderson

Re: Colstrip Units #1 and #2
Application for a
Construction Permit

Gentlemen:

The purpose of this letter is to transmit information supplementing our other replies to the several inquiries written by your Mr. Vichorek in the last several weeks and to transmit information we have previously promised.

Attached to this letter are discussions on the following topics that fall into the above categories:

1. Additional Information on the Pollution Control System

   All the information on this system developed since our permit application was submitted is presented. The vendor's preliminary design drawings are under review by our consulting engineers but no final dimensions have been developed as yet. When these drawings are finalized, they can be provided if desired.

   We have also revised our plant Flow Diagram, Item VII of the permit application, to reflect a design change from bypass air for reheating to a steam supplied plate-coil heater.

Exhibit 4

2. Pilot Plant Results as of February 28, 1973

The results of the pilot plant program available to date are submitted.

3. Particle Size Distribution

In answer to your request for information, we submit graphs summarizing the available test results. These apply to the Corette Plant precipitator inlet.

4. Fluoride Content of Colstrip Coal

Our statistical analysis of the most recent tests is submitted in support of our conclusion that an average value of 33 ppm, oven dry basis, is appropriate (25 ppm as received).

5. Fluoride Emission Prediction

Using all of the recently developed data, we have revised our estimate of fluoride emissions to a number that is smaller than the one we projected in our formal statement on the draft report.

6. Scrubber Technology

We submit additional discussions of the status of scrubber technology in answer to your requests.

7. Nitrogen Oxide Production

We submit references discussing the available data on nitrogen oxide production in tangentially-fired boilers in answer to your request.

8. Cooling Tower Information

We submit the design information on the cooling towers and information on the considerations that were given on minerals carryover and ice and fog formation in answer to your request.

Exhibit 4

You should also receive from Professor Super a separate transmittal of the final one-year data summary from the meteorological program. As soon as he has completed them, we will also forward the summary and final reports.

We would welcome the opportunity to discuss these materials with you at your convenience.

Very truly yours,

David T. Berube

Exhibit 4

SCRUBBER TECHNOLOGY

Sulfur Dioxide Removal

To supplement our previous statements on the capability of sulfur dioxide removal technology to meet the required performance levels, we attach a copy of the Federal Register of March 21, 1972. In this publication, the Environmental Protection Agency reviews the status of this technology. Nine of the twenty installations listed by EPA have or will use venturi type scrubbers. Rather than rewriting this information, we are enclosing the EPA statement as our statement (Paragraph II.2).

Particulate Removal

In the area of particulate removal, venturi scrubbers have long been used for high efficiency collection of particulates finer in nature than fly ash. (Refer to various manufacturers' information, such as Research-Cottrell Bulletin RC-975 and Peabody/Lurgi Bulletin 35000.) Numerous applications of scrubbers for particulate control are discussed in the Los Angeles Air Pollution Engineering Manual. A summary is on Page 231. A recent paper (Mathematical Models for Pressure Drop, Particulate Removal, and SO_2 Removal in Venturi, TCA, and Hydro-Filter Scrubbers, M. Epstein, et al, Second International Lime/Limestone Wet Scrubbing Symposium, New Orleans, LA, November 1971) shows that theoretical equations indicate that 99.5% particulate removal can be achieved at gas velocities and liquid to gas ratios that are compatible with the system sulfur dioxide removal requirements. The same paper reports a good correlation between results predicted by the equations and tests run in a venturi type pilot plant.

In addition to the basic venturi stage, the Colstrip design will utilize a stage of counter-current sprays. Although these are intended to insure adequate SO_2 removal, they will provide additional particulate removal. The previous discussion on the pilot plant operations to date showed that particulate outlet loadings below the maximum guaranteed for Colstrip have been demonstrated.

Fluoride Removal

Numerous articles in the technical literature discuss fluoride removal by venturi scrubbers. A specific article appearing in the March 1958 issue of Industrial and Engineering Chemistry written by K. E. Lunde of the Stanford Research Institute describes the removal of gaseous and particulate fluorides. The concept of the number of transfer units, N_T, is used to compare various types of control equipment.

Exhibit 4

When there is a lean gas mixture at a total pressure of about one atmosphere, the number of transfer units is defined as:

$$N_T = \int_{y_1}^{y_2} \frac{dy}{y-y^*}$$

In many installations, there is no vapor pressure or at least an insignificant vapor pressure for the fluoride compound above the liquid, so $y^* = 0$. The equation reduces to:

$$N_T = \int_{y_1}^{y_2} dy/y = \ln (y_1/y_2)$$

Where:

y = concentration in gas, mol fraction

y_1 = inlet, y_2 = outlet

y^* = vapor pressure above solution, mol fraction

Then:

N_T = Number of Transfer Units = $\ln \left(\frac{1}{(1 - E/100)} \right)$

A table of N_T versus E follows:

N_T Transfer Units	E Efficiency %
1.61	80
1.90	85
2.078	87.5
2.302	90
2.59	92.5
3.0	95
3.68	97.5
3.9	98
4.61	99
5.3	99.5

The article also states water or a basic solution is used as an absorbent for hydrogen fluoride and silica tetrafluoride. Table 1 on Page 296 of I&EC gives two examples each for counter-current sprays and venturi that use water as the absorbing liquor. The two counter-current sprays give 2.5 to 5.85 transfer units while the venturi exhibits 2.0 to 2.9 transfer units.

Exhibit 4

The scrubber at Colstrip contains the venturi stages and counter-current flow stage. If the transfer units for both are added where the 2.0 transfer unit value for the venturi is used and 2.58 for the counter-current sprays, then the efficiency is projected to be between 98% and 99% for gaseous fluoride removal.

Stern in Air Pollution, Vol. III, Page 541 states that a jet-venturi scrubber in a super phosphate plant removes 98% of the fluorine in the exhaust gas. This compares favorably with the projection for Colstrip.

Attached is the article by Lunde in I&EC, and the page from Stern - Air Pollution, Vol. III.

Mr. Daniel Vichorek
Technical Writer
State Department of Health
and Environmental Sciences
Helena, Montana 59601

Dear Mr. Vichorek:

This will acknowledge receipt of your letter of February 22, 1973 concerning the feelings of the Northern Cheyenne people on the coal development now in progress at Colstrip, Montana.

Actually we did not pay too much attention as to what was happening in other areas of Eastern Montana as far as coal development was concerned. We were confronted with our own very serious problems during this period.

We have been quite concerned about the generating plant being constructed by Montana Power Company at Colstrip and I understand that three (3) more such plants will be constructed there at some future date.

We feel that these generating plants will eventually be creating a very serious pollution problem for us and we wonder what effects this pollution is going to have on our other natural resources such as our grass, water and timber.

We are also concerned about the very large number of people who have already moved or will be moving into Colstrip and the surrounding area and the effect they will have on our people. We envision large numbers of the people swarming over our reservation roads and recreation areas.

We are not prepared to handle this type of problem at this time, however, we are making an attempt to be ready for any eventually.

Exhibit 4

We also are very disturbed about the environmental impact statement as far as Montana Power Company's generating plant is concerned. We do not think it was adequately put together and a more meaningful impact statement should be made before the construction permit is issued to Montana Power Company.

I wish to thank you for this opportunity to state our views on Montana Power Company's proposed generating plant. If you need anything further from us please feel free to call or write. I am,

Sincerely yours,

Allen Rowland

RECEIVED
1973
ENVIRONMENTAL SCIENCES
DIVISION

Mr. Daniel Vichorek
Technical Writer
State of Montana
State Department of Health and
Environmental Sciences
Helena, Montana 59601

Dear Mr. Vichorek:

This is in response to your letters of February 5 and 20, 1973 in which you requested information to be incorporated into the final environmental statement that your agency is compiling for the Colstrip generating plant proposed by Montana Power Company and Puget Power.

1. Why is it necessary to build the plant in Montana, and how will Montana Power achieve any savings?

First of all, it appears from your letters that some clarification of Puget Power's status in the project is appropriate. Montana Power and Puget Power are owners as tenants-in-common of the Colstrip plant. Each is the owner of an undivided one-half interest in the entire project including each of the two 350-megawatt generating units. Each company will receive one-half of the output of the project according to its schedules. Montana Power is not building a plant to sell power to Puget Power. However, we do intend to establish a procedure whereby each utility can use a portion of the other owner's capacity in order to obtain the advantage of diversity in meeting peak loads. In fact, we have already entered into a contract pursuant to which Montana Power will receive a substantial portion of Puget Power's capacity at Colstrip during certain months in 1975 and 1976.

With Puget's interest in the plant at Colstrip being constructed at the same time as Montana Power's, significant construction economies can be realized. The engineer contractor for the project, the Bechtel Corporation, estimated the cost differential between the one-unit project and the two-unit project to be in excess of $50 per kilowatt.

Exhibit 4

These construction cost savings represent a significant savings for Montana Power Company and its customers who must ultimately pay these capital costs. It should be noted that Montana Power Company's 350-megawatt plant would have been necessary for its system, and the Company had already begun its plans for Colstrip before Puget decided to join with it in a larger plant.

Since there is currently a net import of electric power to the northeast sector of WSCC, it is essential for system reliability and for system efficiency purposes to construct generation facilities in Montana. Properly balancing the network with added generation at the traditionally weak link of the system, the northeast sector, will improve the reliability of the systems serving that area. In addition, Montana Power will have greater generating reliability because it will own one-half of two units, rather than the whole of one unit, thus facilitating scheduling of maintenance, mitigating the effect of forced outages, and substantially reducing the amount of forced outage reserves that Montana Power must carry. This last item alone represents a substantial savings to Montana Power as its forced outage reserve obligation will be substantially reduced, thus increasing the firm capability of Montana Power's share of the plant.

Since the Colstrip plant will not require new transmission outside the State of Montana, existing transmission systems will be utilized more efficiently. With the only transmission required to be located in Montana, the evidence clearly favors transmission as the alternative to hauling coal to a plant in Western Washington, which was the question posed in your earlier letter. This point is also discussed more fully on Page 5 of Montana Power Company's letter to you dated February 20, 1973.

I trust the above fully answers why the plant is necessary in Montana.

2. Next you ask, "Why is the plant needed at all?" and further request information on Puget Power's load growth.

I am enclosing a copy of Puget Power's 1971 Annual Report, the latest available, which on Pages 18 and 19 presents the financial and statistical record of the Company during a ten-year period, 1961-1971. During this period the annual increase in kilowatt-hour sales has averaged 9.75 per cent, a load increase of over two and one-half times. We are projecting annual increases to average about eight per cent in the next ten-year period as shown on the Table of Loads and Resources furnished to you in Montana Power Company's letters dated January 18 and February 20, copies of which are attached. Puget Power's peak load is projected to increase from an actual system peak load of 2115.2 megawatts in 1972-73 to 4,018 megawatts in 1981-82; and its energy load from 1,210 megawatts in 1972-73 to 2,315 megawatts in 1981-82.

The reasons for this growth are several: growth in number of customers, the primary factor, as well as increased use by each customer. These

Exhibit 4

facts are borne out by the statistics in the Annual Report. Obviously, people find the Puget Sound area a desirable place to live and we do not foresee a significant decline in the rate of population increase in Puget's service area. In fact, new family formations from the existing school age children of Puget's service area alone assures the Company of the reasonableness of the load growth trends noted in the table.

3. Has the Company spent any money on research?

Through the Edison Electric Institute and individually, Puget Power has contributed to research of various alternative power generation methods, including development of the High Temperature Gas Cooled Reactor (HTGR).

Puget and other electric utilities, both public and investor-owned throughout the nation, and government agencies are planning to participate in a research and development program to be carried on by a newly formed research and development organization called Electric Power Research Institute (EPRI). This corporation was formed under the guidance of the Edison Electric Institute with broad support of both public and private organizations. The purpose of this corporation is to provide a technical staff and administration with facilities to embark upon a massive research and development program to invent, design, plan and test with pilot projects new or improved forms of producing, transmitting and distributing electric power and energy that will be feasible to meet environmental standards. The project will include research and development of improved technology and equipment in order to reduce the environmental impact of the generation of electricity by thermal power plants and to develop more efficient utilization of electric energy. The project also includes the construction of the first large-scale LMFBR demonstration plant. Funding of this organization and its research and development program will be by annual payments by all participating electric utilities and other organizations. Puget's total contribution to the LMFBR program is $1,835,000, payable in ten equal annual installments commencing in 1972. Commencing in 1973, the contributions to the LMFBR program will be part of the total commitment to EPRI. It is anticipated that Puget's contribution to EPRI will be $470,000 in 1973 and $761,000 in 1974.

4. Programs for reduction of peak load.

Several years ago, Puget Power initiated a new program for voluntary peak reduction during certain hours on peak consumption days, generally in December and January. This program involves a number of industrial and commercial customers, as well as some schools. The response has been very encouraging. The peak reductions resulting from the program, combined with the curtailment of interruptible industrial and school loads, account for noticeable reduction in the peak hour demands.

Exhibit 4

In addition, Puget has embarked on an extensive energy conservation program directed at the consuming public. This program is currently the principal objective of the Company's advertising program, with all of the communications media being used. As part of this program we have made available a booklet on energy conservation, a copy of which is enclosed. Puget has not implemented any load promotional type of advertising for a number of years. Puget Power application engineers assist customers in choosing facilities and rates to reduce their energy requirements.

5. Is the use of electricity "socially beneficial"?

It is difficult to imagine any use of electricity that is not "socially beneficial." Electric power lights our houses, streets, offices and factories; allows man to be more productive in his work and more relaxed and comfortable at home and at leisure. Electric power serves increasingly more medical and hospital purposes, powers pollution control equipment, and enhances the quality of life for all.

We hope the above will be sufficient to complete the environmental statement in acceptable form. If further information is desired, please let me know.

Very truly yours,

John W. Ellis
Vice President
Utility Management

Enclosures

Exhibit 4

The Montana Power Company

GENERAL OFFICES
ELECTRIC BUILDING
BUTTE, MONTANA 59701

March 5, 1973

Mr. Daniel Vichorek
Technical Writer
Department of Health
Helena, MT 59601

RE: Your letters of February 16, 1973, and February 23, 1973 with questions concerning the environmental impact of The Montana Power Company's Colstrip development.

Dear Mr. Vichorek:

The following is in reply to the above subject.

1. Does The Montana Power Company intend to follow "The Plan for Colstrip" developed by Ken R. White Company?

Western Energy Company, a subsidiary of The Montana Power Company, intends to closely follow the "Plan for Colstrip" prepared by Ken R. White, Denver, Colorado, December 1972. (See attached copy of said plan, marked Exhibit No. 1, and Map 1A)

The plan will be reviewed and updated periodically to reflect alterations in existing development and new, presently unforeseen developments. The plan will be implemented by architect-engineers selected by Western Energy Company. The architect-engineers selected are: Drake-Gustafson, Architects; Christian, Spring, Sielbach and Associates, Engineers; and Wirth Associates, Landscape Architects. The three firms are located in Billings.

2. What does the Western Energy Company expect to do to accommodate the social, recreational, educational and other needs of the expanded population?

The social, recreational, educational and other needs are recognized and accommodated in the "Plan for Colstrip", which

Exhibit 4

will be implemented by Western Energy Company. Colstrip's community facilities include a school, fire and police protection services, churches, health care, library services, parks and recreational services. Some facilities and services, such as water, fire protection and parks are the primary responsibility of Western Energy Company; other facilities and services such as health care and library services are considered quasi-public in that Western Energy Company would be involved to the extent of providing sufficient space. Other needs of Colstrip can be adequately accommodated by existing public facilities, such as existing schools.

It is the intent of Western Energy Company to work closely with local, county and state groups to ensure an orderly, attractive development of the community of Colstrip.

There follows a more specific discussion of the services and facilities contemplated to accommodate the social, recreational, educational and other needs of Colstrip.

(a) Social Needs

Library services will be provided through a bookmobile from Miles City, Montana. (Page 28 - Ken R. White, Supra.) Two additional church sites are provided in the Plan. If new churches do not organize, the property can be converted into additional residential lots. (Page 27, Ken R. White, Supra.)

Western Energy Company intends to promote civic organizations which will contribute to a good social community environment.

(b) Educational

In relation to schools, Western Energy Company has reviewed with local school authorities the impact Colstrip development is expected to have on enrollment. School authorities then can take appropriate action for school expansion (Page 25, White, Supra.) Western Energy Company will contribute significantly to the tax base for the operation of schools.

(c) Recreational

The plan for parks and recreation includes further landscaping of existing parks, development and expansion of the proposed teen and community center and development of new play fields, tot lots and parks. (Pages 28-33, White, Supra.)

Several other recreational developments are recommended or planned outside the town, such as a golf

Exhibit 4

course, lake and picnic areas, rifle and pistol ranges, snowmobile and motor trails, wildlife and nature areas. (Pages 33, White, Supra.)

(d) Other Needs
Western Energy Company owns and maintains a number of single-family homes, apartments and a mobile home park. Detailed plans have been developed for expected growth and even growth beyond present growth expectations. (Pages 14-16, White, Supra.)

The architect-engineers hired by Western Energy Company will study the drainage and sewage needs of the area. Western Energy Company plans to provide for an increased water consumption. Western Energy Company has built a new 500,000 gallon water tank and will put in some new transmission pipes. Other existing utilities are deemed to be adequate for future requirements. (Pages 39-44, White, Supra.)

Commercial development is planned for the area. Provisions are made for a grocery store, drug and hardware store, general store, offices, medical facilities, a post office and space for such services as a laundromat, beauty shop, barber shop, service station, motel and restuarant are planned. (Pages 21-24, White, Supra.) Private enterprise should participate in the development of said facilities.

3. What are present and future costs of locating the plant at Colstrip compared with a site nearer load centers?

Comparative studies done by Montana Power Company based on total revenue required and levelized annual cost of expenditure indicate that it is slightly more economical to locate the plant at Colstrip than in other potential areas such as Springdale or Cushman.

There follows a partial summary of this study.

Exhibit 4

Two Units 1974-1985

	Total Revenue Required	Percent Difference	Levelized An. Cost	Percent Difference
Colstrip	$ 279,189,000	Base	$ 21,427,000	Base
Springdale	281,142,000	+ .52%	21,494,000	+ .32%
Cushman	281,989,000	+ .82%	21,626,000	+ .93%

Two Units 1974-2013

Colstrip	$ 1,089,103,000	.10%	$ 24,328,000	Base
Springdale	1,152,497,000	+6.05%	24,983,000	+3.20%
Cushman	1,129,406,000	+3.81%	24,849,000	+2.37%

Although the study showed the Colstrip site to be more economical the difference is less than 1%. Envirnomental and other considerations such as uncertainties in freight rates and freight performance for transportation of coal were the more persuasive reasons in the selection of Colstrip. (See our letter of February 12, 1973.)

4. Will the minerals in the drift precipitate out within 200 feet of the towers?

All minerals should precipitate out within 2,000 feet from the place of emission, and 60% of all minerals should precipitate out within 1,000 feet of the place of emission according to diffusion specialists of Bechtel Corporation.

Fog and ice formations should not develop beyond 200 feet from the cooling towers, according to cooling tower specialists of Bechtel Corporation. In reliance on Bechtel authorities, The Montana Power Company plans to construct its plant 200 feet in the direction of the prevailing winds from the cooling towers. The state highway is approximately 3,500 feet in the direction opposite the prevailing winds.

The Montana Power Company considers Bechtel Corporation to be a reliable authority on matters relating to cooling towers and mineral drift because Bechtel is one of the most experienced authorities in these areas. Bechtel Corporation is a worldwide Contractor which has constructed many different types of power plants.[1] (See also data submitted by Mr. Dan Berube at meeting in Helena on March 2, 1973)

Exhibit 4

5. How may cells will there be in the cooling towers, and what is the rated horsepower of the fans?

There are seven cells in the cooling towers and each of the seven fans has a rated horsepower of 185.2 according to the manufacturer.[2] (See also data submitted by Mr. Dan Berube at meeting in Helena on March 2, 1973)

6. Is any noise pollution from the Colstrip plant anticipated?

NO. There follows noise level specifications as set forth in the manufacturer's data sheet.[3] (See also data submitted by Mr. Dan Berube at meeting in Helena on March 2, 1973)

Noise Level (SPL - DB re 0.0002 Microbar at Ground Level 100 feet from Louvers at Center of Tower):

Octave Band		1	2	3	4	5	6	7	8	Weighted Freq. Band			
CPS:	From	20	75	150	300	600	1200	2400	4800				
	To	75	150	300	600	1200	2400	4800	9600	A	B	C	Flat
DB		84	83	82	78	74	72	68	64	81	NA	NA	NA

7. What are the known operating characteristics of tangentially fired furnaces of the types hereinvolved and what is the measurement of nitrogen oxides in the stack gases of a unit hereinvolved?

The tangentially fired furnaces hereinvolved have the lowest nitrogen oxide production of any furnace.

It is also important to note that the performance of the type of furnace hereinvolved was adopted by the Federal Environmental Protection Agency as the standard under the Federal Clean Air Act. (See also data submitted by Mr. Dan Berube at meeting in Helena on March 2, 1973)

8. Has Montana Power Company done any research on the development of any other type of generating facility?

The Montana Power Company individually has not done any extensive research regarding other forms of generating facilities. However, The Montana Power Company is a member of, and supports the Edison Electric Institute,[4] which has done research on all forms of power generation.

Exhibit 4

9. Is there reason to think Montana's annual 5% increase in energy demand will not continue?

Montana's energy demand is expected to continue to increase at least at its present rate. This projection is based on and consistent with national projections, historical experience in Montana and particular known factors about Montana's future supply and demand.

Forecasters of the Federal Government and the electric industry expect the demand for electricity to continue to grow at an average rate of 7% a year with a doubling every 10 years.[5] Attached is a chart, marked Exhibit No. 2, from the 1970 National Power Survey of the Federal Power Commission showing past and future energy requirements in the west region of the United States. The peak demands by load centers from the same National Power Survey shows the demand on certain Montana supply areas to increase from 1,460 megawatts in 1970 to 2,590 megawatts in 1980.

Power supply area	Load Center	Peak demand--megawatts 1970	1980	1990
30	Butte-Anaconda	700	1,240	2,260
	Billings	175	312	563
	Helena-Great Falls	330	587	1,060
	Kalispell-Missoula	220	390	707
	Unassigned	35	61	110
	TOTAL	1,460	2,590	4,700

Studies by The Montana Power Company, based on historical data, also indicate a significant increase in future demand for electric power in Montana. (See Attached Exhibit No. 3, "The Montana Power Company Annual Average Electric Energy Loads", Exhibit No. 4, "The Montana Power Company Annual Peak Loads", Exhibit No. 5, "The Montana Power Company Electric Load Peaks and Average" and Exhibit No. 6, "The Montana Power Company Electric Load Peaks and Average (Future)".

Furthermore, it is important to note that The Montana Power Company has had a deficiency in self-generated electric power in past years. Presently this deficiency is accommodated by purchases and exchanges with other utility sources.

For example in January 1973, The Montana Power Company's self-generated resources of electric power total 768 megawatts. The Montana Power Company received an additional 263 megawatts from other utility sources.[6]

Exhibit 4

By 1975 many of these other sources of power will no longer be available. By 1975 the peak load demand in Montana is projected to be 1098 (See Exhibit No. 4, Supra). Obviously Montana Power's present self-generated total of 768 megawatts would not be sufficient to meet the projected 75-76 peak load requirement of 1098 megawatts. This is why "brownouts" are anticipated by 1975. Although these projections of future energy loads of The Montana Power Company set forth in Exhibits No. 3 through No. 6 are based primarily on historical experience, and although power projections are subject to a number of variables, other known factors must be anticipated and taken into consideration. For example, U. S. Plywood and Champion paper of Missoula will need a significant increase in power for expanded activities in about 1974, and the Anaconda Company will need about 25 additional megawatts for its new Great Falls smelter by 1975.

10. If an increased number of television sets, water heaters and electric ranges have caused the energy demand to grow faster than the population since 1961, what indication is there that this growth rate will continue?

First, it is important to note that residential usage in which water heaters, televisions, etc. are included as a rather small part thereof, is itself only a smaller portion of electric power usage in Montana. For example in 1972 residential usage amounted to 20% of the total electric power usage from Montana Power Company.

Commercial and industrial usage accounts for 2/3 of Montana Power Company's electric usage.

Several signs of growth, such as population growth, rise in the living standard, rise in recreation and tourism and employment for Montana in the decade 1970-1980, are evidence of the continued growing need for electrical energy in Montana for both residential and industrial usage.

Secondly, in addition to the projection or more people and industry in Montana which will require more energy, the present market of electric energy is not exhausted. For example, only 75% of Montana's potential residential customers have electric ranges, only 60% have electric dryers, only 14% have outdoor lights and only 9% have air conditioning. The percentage of customer growth has been the highest in history in the past two years for Montana Power Company and is expected to continue.

11. Is there any specific information on how much power is now used and will be used by farmers, sewage plants and other environmental facilities?

The Montana Power Company's marketing personnel think farm and environmental usage has and will continue to expand. For example, the following is the annual added usage for irrigation purposes.

Year	Horsepower Added
1961	1380
1962	1333
1963	1622
1964	2163
1965	2042
1966	1643
1967	2767
1968	2582
1969	2081
1970	2743
1971	4643
1972	4292

It is projected that the amount of energy used for environmental improvement on a national basis will increase from about 2% of total energy consumption in 1970 to 4 or 5% in the period 1970-1985.[8] In Montana, sewage and water treatment facilities in Billings and Great Falls will each alone use enough electricity to serve an average Montana town with a population of 10,000.

Montana industry is also using an increasing amount of energy to improve air and water quality.

The Humble Oil Company in Billings has a water treatment system that returns their water effluent to the Yellowstone River in better condition than the water that comes into the plant. They use four 50 HP electric motors on large aerators in the ameliorating process. Great Western Sugar Company in Billings is constructing a new sewage treatment facility that will require 600 to 700 HP in electrical load. Furthermore, the air pollution equipment to be installed in the Colstrip plant will use approximately 25 megawatts of power, which is approximately 1/30 of the total electricity now generated by The Montana Power Company.

12. If so few Montana homes are electrically heated, why do the annual peak loads occur in the winter?

Montana Power Company's peak load occurs in winter because the temperature is colder and the days are shorter which results in greater uses of electricity. For example, with shorter days more lighting is required. With shorter days and colder weather there is a tendency for people to be indoors and use more electricity for lighting, clothes drying, hot water and heating. In addition, to electric heat, forced air and natural gas heating systems use electric thermostats, fans and blowers. Of course, residential

use of electricity is only part of the power drain experienced during winter in Montana. Montana industrial and commercial customers also consume added energy loads in winter, because of colder temperatures and shorter days.

13. What workers are included in the Montana Power Company's projected payroll figures, and are theses figures consistent with population projection of Ken R. White?

The Montana Power Company's payroll figures are based on payroll estimates for construction, operation and mining employees for particular months and years. (See Exhibit No. 7) Population projections by Ken R. White are also based on an estimate of the number of construction, operations and mining employees but additionally White's estimates are also based on professional and support personnel. (See White's "Population Projections", Supra, Exhibit No. 1, Page 10.)

Secondly Montana Power Company's payroll estimates and Ken R. White's population projection are in fact consistent. For example, The Montana Power Company's payroll estimates peak in early 1975. Similarily Ken R. White's population figures peak in 1975. (See Population Growth Table 2, White, Supra, Exhibit No. 1, Page 12, 13.)

I believe this completes the information requested in your letters of February 16, 1973, and February 23, 1973. If I can be of further assistance, please let me know.

Sincerely,

John W. Ross, Esq.
The Montana Power Company

SUMMARY

(x) Draft ( ) Final Environmental Impact Statement

Montana Department of State Lands
U.S. Office of Surface Mining

Type of Action: (x) Administrative ( ) Legislative

Western Energy Company proposes to begin mining in Sections 1, 2, 3, and 11 in T1N, R40E, and has submitted a mine permit application for this proposed action. The Commissioner of State Lands and the Secretary of Interior must decide whether to 1) approve the permit as proposed; 2) approve the permit with stipulations; or 3) deny the permit or portions of the permit.

Brief Description of the Company's Proposal:

Western Energy proposes to remove an estimated 24 million tons of coal from an area of 709 acres over a period of five years. An additional 1,145 acres would be used for shop facilities, haul roads, topsoil stockpiles, boxcut and highwall reduction areas, a crusher facility, and the coal conveyor. The mine plan permit area would total 3,104 acres, 1,227 of which would not be disturbed. Coal would be transported to Colstrip Units 3 and 4 for power generation via a coal conveyor.

Mining is anticipated to begin in 1983 and proceed until 1988, and active reclamation of the area in question will continue until at least 1991.

Western Energy has not submitted to OSM or DSL a complete life of mine proposal for Area C, although the company would probably implement a 34-year mine plan during Block I mining. Over the entire Area C life of mine, approximately 5,040 acres would be mined and an additional 2,862 acres disturbed by related activities.

Summary of Impacts by Discipline:

- Geology - geologic impacts would be minor, including disruption of the stratigraphy by removal of the Rosebud coal and replacement with spoil material, general smoothing and a slight lowering of the topography, possibe creation of gullying and slumping along the highwall/backfill interface and to a lesser extent in other areas in the reclaimed spoils, a slight decrease in electrical conductivity in the near-surface material, and potential localized increases in molybdenum, nickel, or cadmium in near-surface layers.

- Hydrology - groundwater aquifers would be distrupted by mining and replaced with spoils that would have similar flow characteristics to the original aquifers. Groundwater flow would be intercepted by the pit during mining. The majority of groundwater discharge

to the pit would occur immediately after the pit is opened and would diminish with time. The water levels in the spoils would eventually reach pre-mining levels.

The concentration of total dissolved solids in the spoils aquifer would be approximately twice that of the present Rosebud coal and overburden aquifers. Spoils water would follow the regional southeast flow direction and would eventually reach Cow Creek. The quality of water in aquifers underlying the Rosebud coal would generally not be affected by the placement of spoils. Water discharging at the boundaries of the mined area to streams would have no appreciable effect upon surface water quality. However, water discharging from the spoils to the valley fill of East Fork Armells Creek would displace water in the valley fill and would increase concentrations of total dissolved solids.

In general it is anticipated that few surface water changes would occur during the first five years of the Area C permit period. The probable impacts to the surface water hydrology over time would include a decrease in the total volume of runoff from the mined areas, a reduction of peak flow magnitudes, and the near-total removal of sediment introduced to the streams from the mined areas, all due to the placement of sediment ponds. Sediment ponds may also cause an episode of high erosion upon removal. Seepage from the proposed fly ash pond associated with additional power generating facilities in Colstrip would constitute an indirect impact of mining. Possible increases in salinity attributed to pond seepage could have detrimental impacts on Cow Creek.

- Climate - mining in Area C would have no impact on the climatic regime in the area.

- Air quality - a slight increase in fugitive dust would occur in the locality of the mine. Projected levels would be far below federal and state air quality standards and would represent a minor impact. Impacts to the townsite of Colstrip and to the Class I area (the Northern Cheyenne Indian Reservation) would be below detection limits.

- Noise - increased noise levels due to construction, operation of mining equipment, or blasting would be audible only near the site and would not influence the noise levels presently occurring in Colstrip.

- Soils - soils of the area would experience mixing and some alteration of chemical and physical properties. These changes would influence the post-mining potential for crop production and might limit the successful establishment of conifers or warm-season grasses. Organic matter of the soils would decrease, bulk densities might increase, and nutrient cycling in the soil would take a number of years to reach equilibrium.

- Vegetation - impacts to vegetation would include a temporary disruption of vegetative cover and reestablishment of vegetation dominated by productive cool-season grasses and legumes. Most crop and pasture areas would be replaced with native grasses and legumes. Forage production would increase with an accordant increase in the grazing capacity over pre-mine levels, but may not equal the potential forage productivity that could be achieved on the existing range sites. There would be a likely decrease in warm-season grasses when compared to pre-mine conditions and a significant decrease in the potential for warm-season grasses on the post-mined soils. Shrub cover would decrease and there would be fewer areas of ponderosa pine in the post-mined areas.

- Wildlife - several wildlife habitats would be temporarily destroyed by the project, and a long-term reduction in ponderosa pine stands and shrub habitats and their associated wildlife would result in the mined area. Sharp-tailed grouse dancing grounds may be substantially disturbed. An inactive golden eagle nest may experience some secondary impacts due to nearby mining activities. Continuation of mining through the remainder of Area C would destroy an eagle's nest and two sharp-tailed grouse dancing grounds.

- Sociology and economics - population increases contributed by the project would be greatest in the second quarter of 1983, and would postpone but not prevent the decline in population due to completion of Colstrip power generating Units 3 and 4. Social impacts would be small due to the similarity of existing and incoming work forces and is not expected to significantly affect the level of services required. An 11 percent increase in revenues or expenditures could be expected for any given year.

- Land use - the mine and associated disturbances would displace 606 acres of cropland, of which all but 60 acres would be reclaimed to rangeland following mining. Temporary displacement of grazing would occur over much of the area to be mined, to be restored in some reclaimed areas prior to bond release and in the entire area after mining is completed.

- Transportation - four miles of East Fork Castle Rock Road would be permanently relocated. Current daily traffic volumes would increase by less than five percent during both construction and operation phases of the mine.

- Recreation - recreation resources in Colstrip and Rosebud County are presently insufficient to serve the existing population. The project would serve to prolong the period of high population, thus extending these use pressures; however, the anticipated decline in Colstrip's population by 1985 or 1986 due to completion of Units 3 and 4 and winding down of Area C construction would reduce all of the project-related population increases.

- Cultural resources - Nine cultural resource sites are located within Area C, Block 1, and 25 are located within a one-mile buffer zone around Area C, Block 1. Seven of the nine cultural resources within Area C, Block I woould be partially or totally destroyed. Of these seven sites, four appear to be eligible for the National Register of Historic Places, four do not appear eligible, and one needs additional work before an eligibility determination can be made.

  Eleven of the 25 cultural resources sites within the one-mile buffer zone contain rock art or standing structures and coule be affected by blasting. Another site, not containing rock art or standing structures, will be directly impacted by road relocation. Of these 12 sites that may be impacted, two have been determined and one appears to be eligible for the National Register.

- Aesthetics - the landscape would experience an alteration in color, contrast, and texture due to the reduction or loss of ponderosa pine, shrub areas, and sandstone outcrops, none of which are intrinsically unusual for the region.

Relationship between short-term uses of the environment and long-term productivity:

The 166 million tons of coal mined from Area C would serve as the sole source of fuel to be burned in Colstrip generating Units 3 and 4. This short-term use of the Block I mine site would last through 1988, when mining in Area C, Block I would end, and through 2017 for all of Area C when the economically recoverable coal would be exhausted. If the mine area were not disturbed, it would continue to produce winter wheat, livestock forage, wildlife habitat, and limited scenery. Crop production, wildlife habitat, and scenic value will be reduced after reclamation. Compared to the pre-mining (1978) conditions, productivity for livestock grazing would increase, however the potential productivity of the post-mined area would be lower than the pre-mining potential, primarily due to the loss of discrete sandy soil areas.

Irreversible and irretrievable commitments of resources:

Under the Block I proposed mine plan, the mine would produce 23.7 million tons of coal from the Rosebud seam and leave 9.6 million tons of the lower quality McKay coal seam, for which no current market exists. Future mining would be unlikely if a market became available, due to very high overburden thickness. For the entire Area C life of mine, about 166 million tons of coal would be recoverdd from the Rosebud seam. About 66 million tons of coal would be left in the McKay seam. The McKay seam would probably not be mined in the future.

If federal leases become available adjacent to the Block I area, overburden averaging might allow recovery of additional coal that is considered unminable under the proposed Block I mine plan. If this

Exhibit 3

option becomes available after the mining of Block I, a significant amount of coal in these areas would be unavailable for future mining.

The existing stratigraphy would be permanently altered, however, the stratigraphy is not unusual or intrinsically valuable. The existing topography would be altered, and mixing of stratigraphy and overburden would alter the character and land use potential of the reclaimed surface. The likelihood of establishing a vigorous productive vegetative cover is excellent, however vegetative diversity and successful establishment of conifers or certain shrubs may be limited after mining.

CHAPTER I

DESCRIPTION OF THE PROPOSAL UNDER CONSIDERATION

A. SCOPE OF THE ANALYSIS

Western Energy Company (Western Energy) has applied to the Montana Department of State Lands (DSL) and the Office of Surface Mining (OSM) for a surface mine permit for Area C, Block I of its Rosebud Mine near Colstrip, Montana (Figure I-1). The company proposes to permit a five-year mine area encompassing 2,693 acres referred to as Block I, as shown in Figure I-2. The sequence of mining proposed for Block I is depicted in Figure I-3.

Under the provisions of the Montana Strip and Underground Mine Reclamation Act, DSL must approve the mining and reclamation plan (hereafter called the "mine plan") for the proposed Block I mine area before mining or related facility construction can begin. Federal approval to begin mining must be obtained from the U.S. Department of the Interior, Office of Surface Mining (OSM). In addition, the federal coal lease in Section 2 T1N, R40E will have to be renewed in August of 1986.

The Block I mine plan was submitted by Western Energy as a complete life of mine plan, scheduled to be terminated with complete reclamation of the proposed five-year mining area. This mining plan was developed and submitted because the company did not have federal coal leases in Sections 4 and 10, T1N, R40E or Section 12, T1N, R41E. Without these key leases, continuous mining directly from Block I through the remaining 5,300 acreas of Area C would not be economically feasible.

On April 28, 1982 the Bureau of Land Management held a coal lease sale at which Western Energy submitted the apparent high bid for these and other parcels. The issuance of leases usually follows a sale by several months. This sale has been challenged and may delay or prevent issuing the leases. Nevertheless, it appears reasonable to assume that the company may eventually obtain these leases and implement the 34-year life of mine plan for Area C, known as Block II.

The Block II mine plan would begin in the proposed Block I permit area during the second year if the company obtains the leases prior to completing the third mining cut. A comparison of Figures I-3 and IV-1 will illustrate the reorientation of the mining pits required to initiate the Block II plan.

The pit realignment and its environmental effects within the proposed Block I mine area are discussed in Chapter IV, Section B.

This EIS is designed to serve as an informational and environmental document for the OSM, DSL, and the general public, in compliance with the National Environmental Policy Act (NEPA) and the Montana Environmental Policy Act (MEPA). Technical Support Documents for this EIS are available for public review at several locations (listed in Chapter V) throughout the state. Prior to approval of the surface mining permit

Exhibit 3

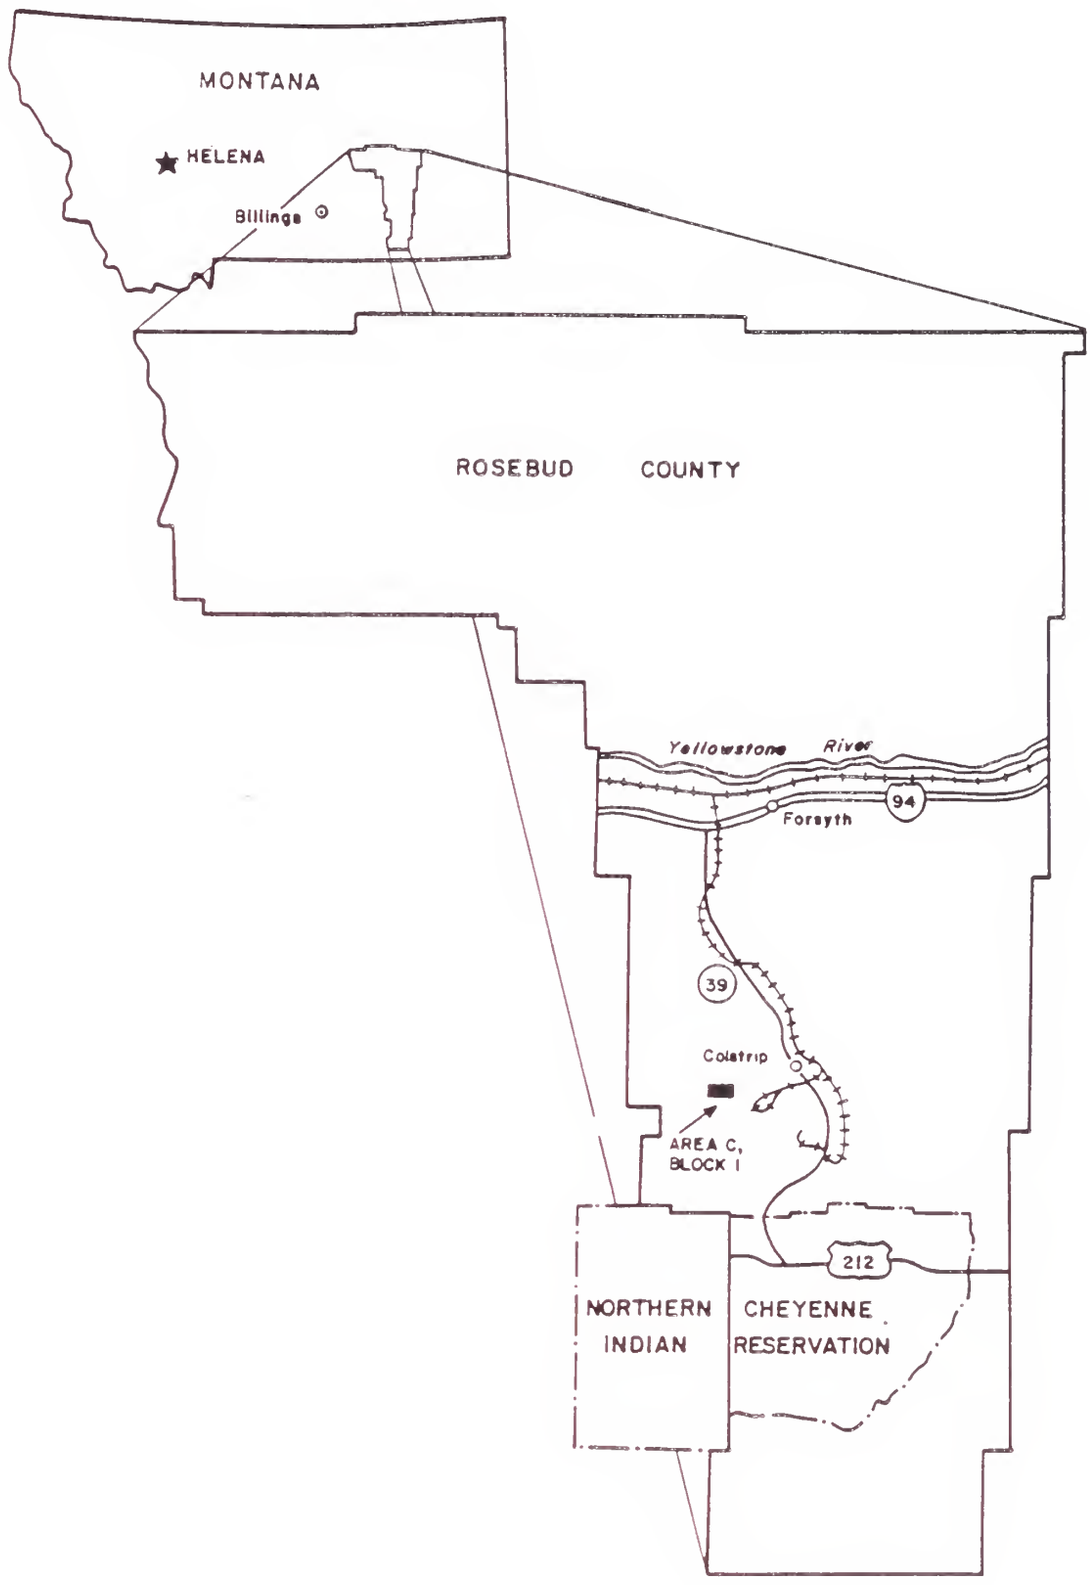

FIGURE I-1 LOCATION OF AREA C, BLOCK I

Exhibit 3

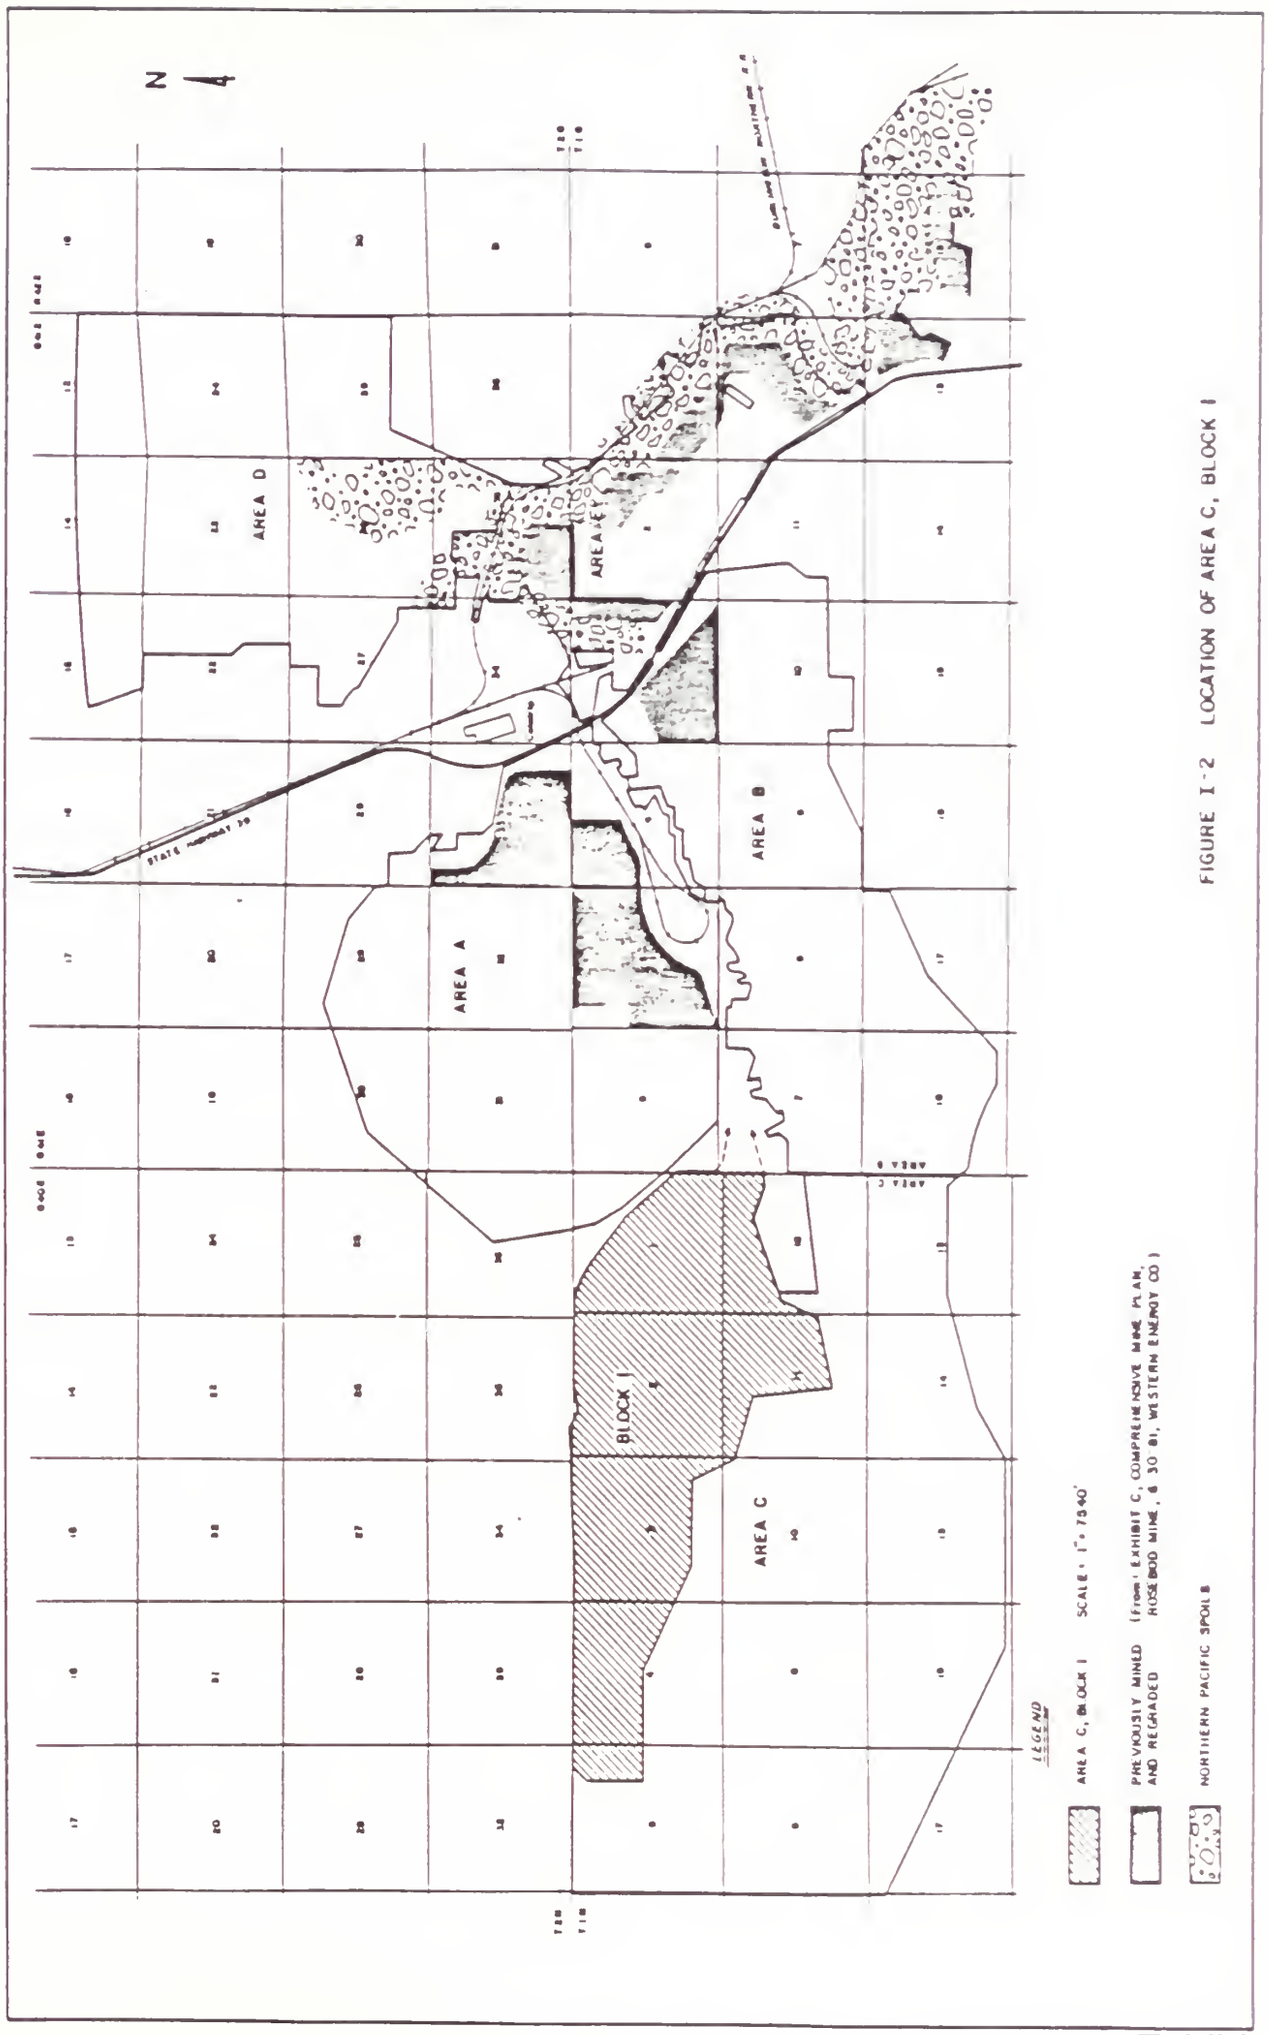

FIGURE I-2 LOCATION OF AREA C, BLOCK I

Exhibit 3

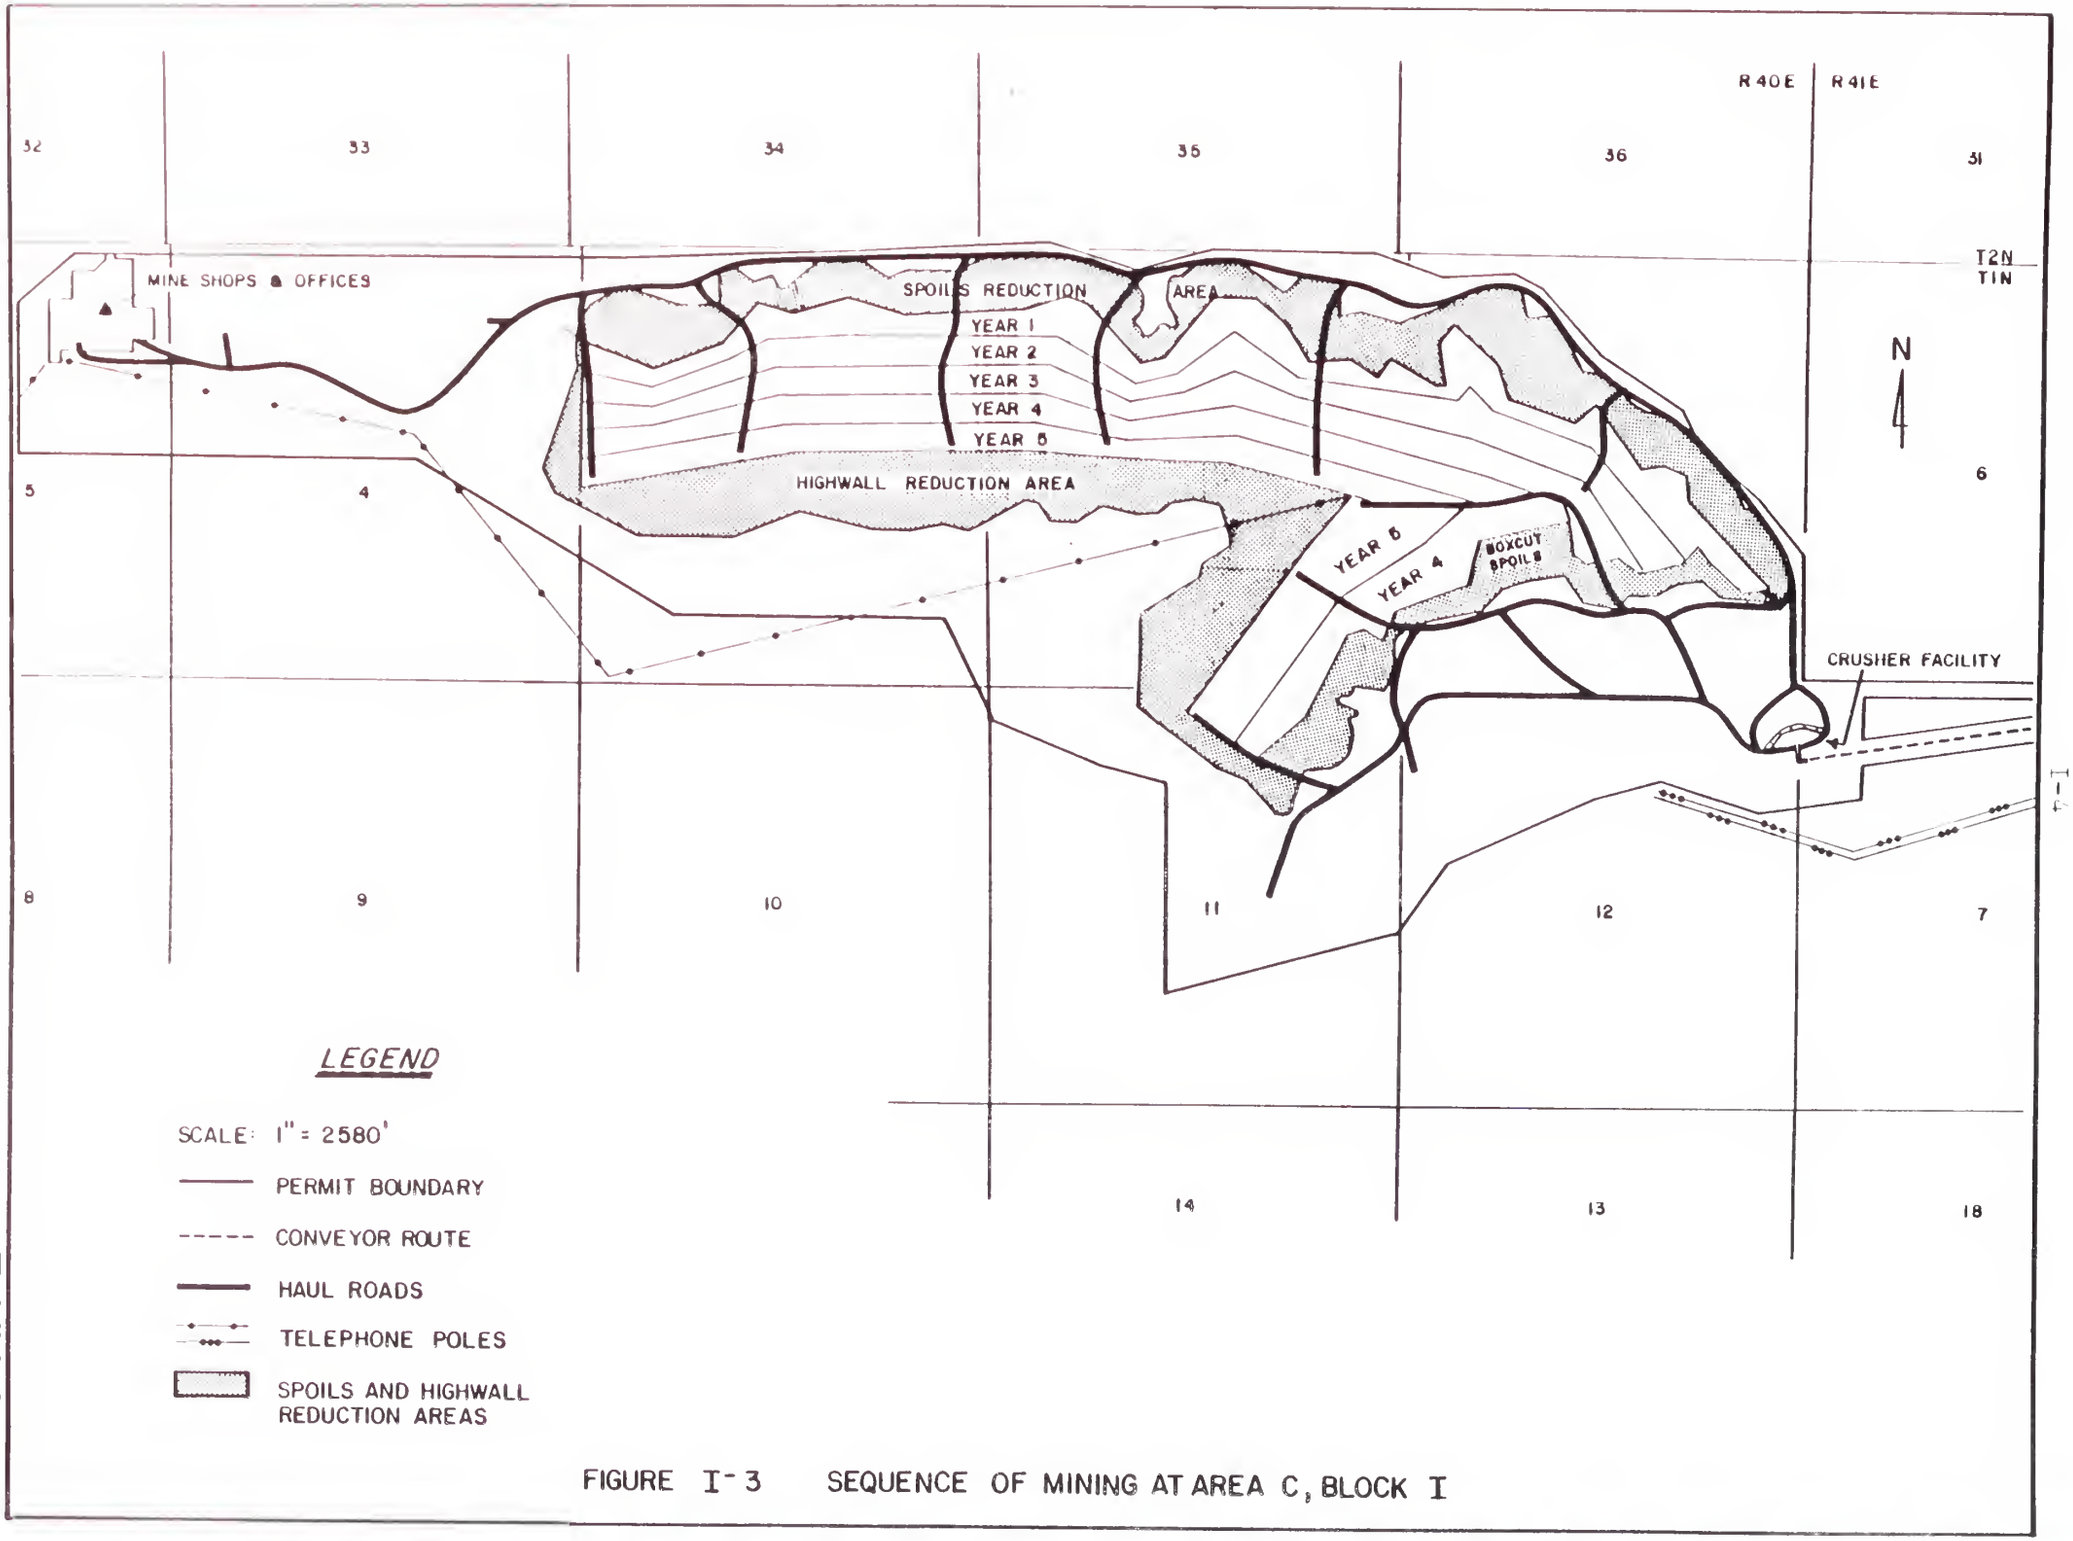

FIGURE I-3 SEQUENCE OF MINING AT AREA C, BLOCK I

Exhibit 3

application, a findings of compliance with the federal and state surface mining statutes must be made by the regulatory agencies (OSM and DSL). Approval of the permit is a process separate from the EIS.

Only two other permits are required to conduct the proposed surface mining operations, aside from the surface mining permit: an air quality permit and a water pollutant discharge permit, both of which are issued by the Montana Department of Health and Environmental Sciences (DHES). The DSL has entered into a Memorandum of Understanding with the Department of Health and Environmental Sciences stating that the Area C, Block I EIS will satisfy the Air Quality Bureau's MEPA needs regarding the issuance of an Air Quality Permit.

Western Energy has applied to the DHES to amend the existing air quality permit for the Rosebud Mine (Permit #1483) to include the proposed activities at Area C, Block I. Western Energy will also be applying for a water pollutant discharge permit from DHES. Although DSL does not issue air and water quality permits, the agency can require measures to control fugitive dust and water pollution from mined lands and reclaimed areas.

Previous EISs have been prepared for mining and mining-related projects in and adjacent to the Rosebud Mine, and have been used in the preparation of this document. Among these are the Northern Powder River Basin EIS (U.S. Department of Interior, 1979), the Colstrip Project EIS (U.S. Department of Interior, 1979), the Rosebud Mine Area B Extension EIS (MDSL, 1980), and the Rosebud Mine Area E Extension EIS (MDSL, 1981). The Colstrip Project EIS (1979) specifically addresses the potential impacts of mining in Areas C and D of the Rosebud Mine.

Presently, in addition to this site-specific EIS, a comprehensive EIS is being prepared to evaluate the impact of mining at the Rosebud Mine for the life of the mine, through the year 2017. The comprehensive EIS will address the cumulative impact of all proposed mining activities at the Rosebud Mine in relationship to all other mining and industrial activities in the area around the Rosebud Mine (Figure I-4). Several EISs for other projects in the Rosebud County area are currently in progress or proposed, including Western Energy's Area B and MONTCO's EIS. The impact from these proposed mine areas, the Big Sky Mine, and other projects for which no EISs are available were considered during the preparation of this EIS. The locations of other active mines close to the Rosebud Mine are depicted in Figure I-4.

B. MINE HISTORY

Surface strip mining of the coal resource was begun in the Colstrip area by Northern Pacific Railroad. During the period from 1924 to 1958, Northern Pacific extracted approximately 44 million tons of coal from the Rosebud seam to be used for steam locomotives and domestic purposes, resulting in approximately 1,800 acres of surface disturbance.

When the Northern Pacific Railroad changed from steam locomotives to diesel locomotives, mining ceased. In 1959, the mining leases and the townsite of Colstrip were purchased by Montana Power Company (MPC). In

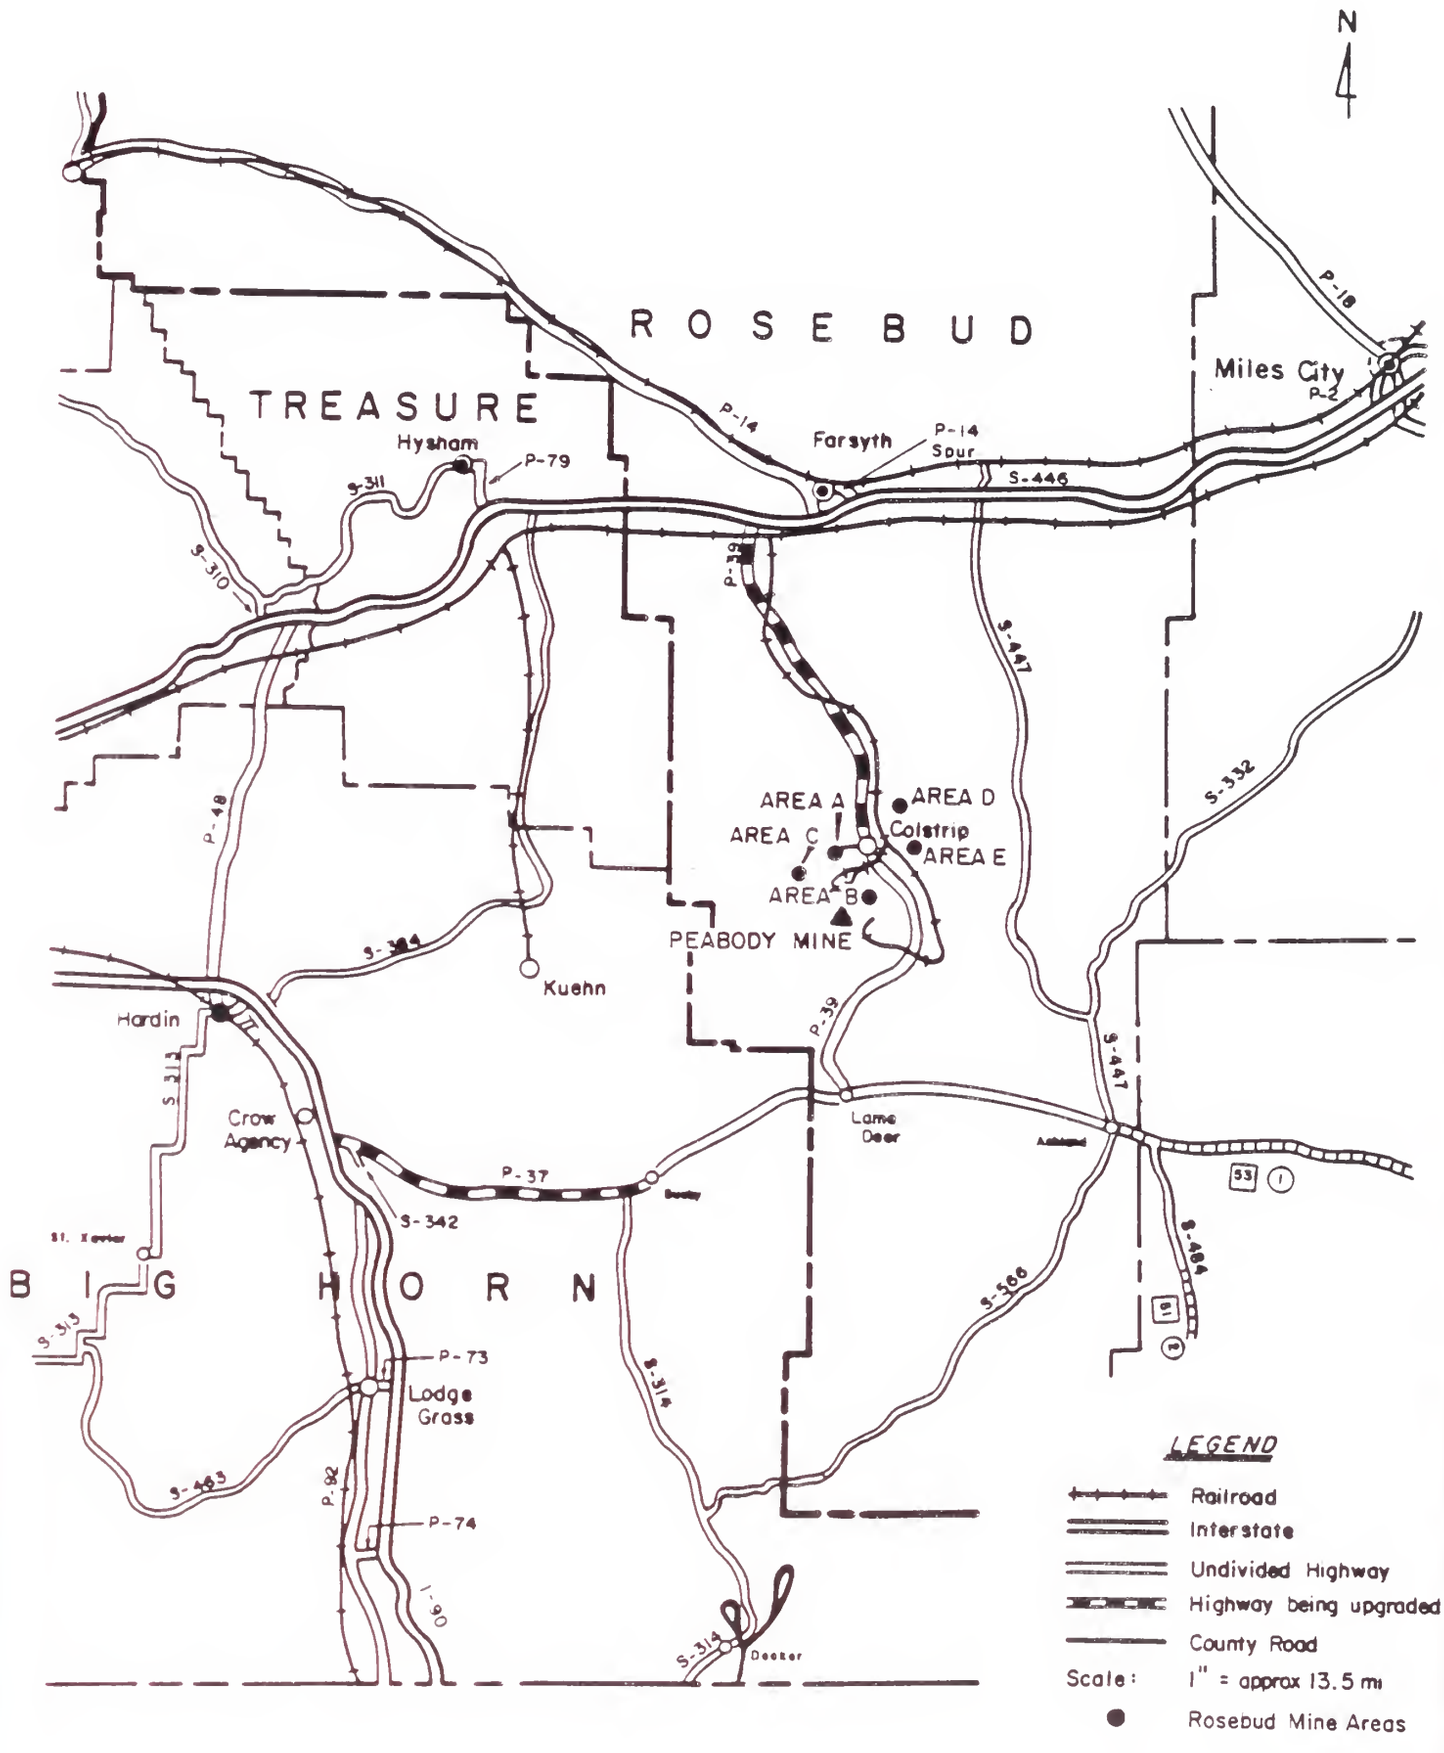

FIGURE I-4 LOCATION OF PEABODY MINE IN RELATION TO THE ROSEBUD MINE AREA

Exhibit 3

1966, Western Energy, a wholly owned subsidiary of MPC, was formed to manage and develop the properties. In 1968, Western Energy began mining the coal of the Rosebud seam adjacent to Northern Pacific's old workings in an area called Pit 6. Western Energy has subsequently completed mining in Pit 6, and has expanded mining of the Rosebud seam in Areas A, B, and E. Numerous permits have been granted and numerous EISs written related to mining in these areas. Copies of each permit application and EIS are on file with DSL in Helena, Montana.

Table I-1 shows the approximate projected annual coal production by year from Area C, Block I during the period from 1983 through 1988 and the approximate annual production in five year increments for the remainder of Area C.

C. WESTERN ENERGY COMPANY'S PROPOSAL

1. Summary

Western Energy's proposed Area C, Block I mine is in southwestern Rosebud County, Montana, about five miles west of the town of Colstrip (Figure I-4). Coal would be transported by conveyor from the mine to MPC's Colstrip power generating facility, Units 3 and 4, a distance of about four miles, and would become the sole source of fuel for these units.

Coal production from Area C, Block I would average 4.7 million tons of coal per year over the five-year mining period, ranging from 3.8 million tons for the first year to 5.6 million tons for the fifth year. These reserves would be mined through the year 1988 at an average annual rate of 4.7 million tons per year. The probable life of mining activities in Area C is expected to be at least 34 years, with the anticipation that successive five-year mine blocks would be permitted sequentially after Block I.

Of the six coal seams underlying the proposed mining area, only the uppermost two, the Rosebud and the underlying McKay, are of economic importance. Western Energy mines only the Rosebud seam, because a market has not been found for the McKay coal, which has a higher sulfur content than the Rosebud coal and has a tendency to form slag in some steam boilers.

The land surface in Area C, Block I is owned by Burlington Northern, Inc. and Farley's, Inc. The coal to be mined is leased by Western Energy from Burlington Northern and the federal government. Surface ownership and coal leases for Area C are shown in Figures I-5 and I-6, respectively.

The increased labor force required for early construction phases would be approximately 300 to 400 people, with a net increase of approximately 200 people to operate the mine and support facilities.

TABLE I-1

APPROXIMATE ANNUAL PRODUCTION BY YEAR

Year		Five Year Plan Production (Million Tons)
1	9/83-8/84	3.8

Exhibit 3

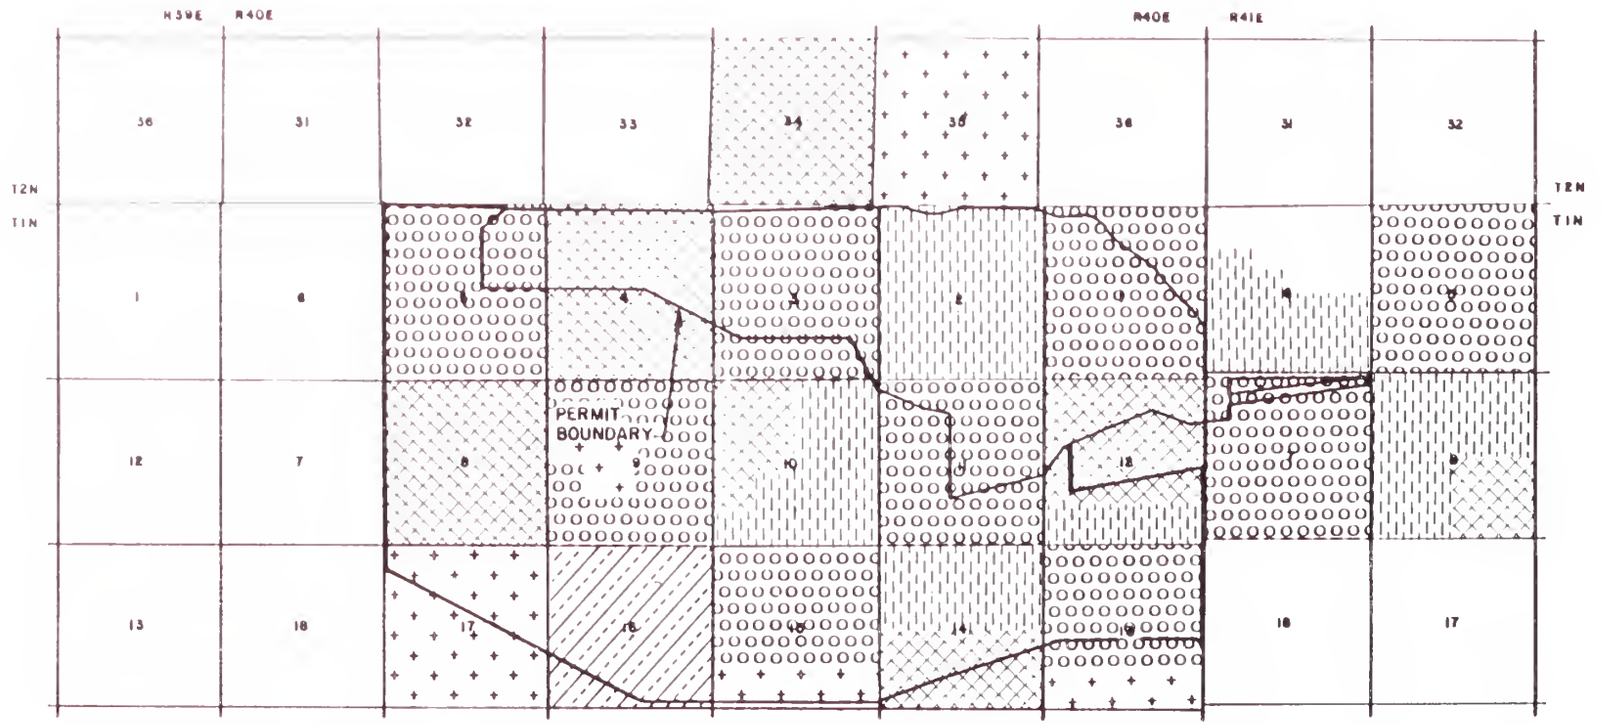

FIGURE I-6 -- COAL LEASES AT AREA C, BLOCK I

Exhibit 3

2. Facilities

Western Energy plans to construct two separate facility complexes to support the Area C, Block I mine operation: (1) a shop and office facility; and (2) a coal crusher and conveyor facility, with an associated overland conveyor corridor beginning at the crusher facility and extending a distance of four miles to MPC's electric generation Units 3 and 4 (Figure I-7). All but one mile of the conveyor system will pass through areas presently permitted to Western Energy in Areas A and E. Facility construction is scheduled to begin in August of 1982 and will be completed by July of 1983.

The new shop and office facilities will include:

- An office building
- A parts warehouse, with adjoining storage yard
- A lubricant storage building, with adjoining fuel storage tanks
- An equipment repair building
- A machining and welding building
- A crew change building, with adjoining parking lot
- A sewage treatment facility
- Adjacent parking facilities

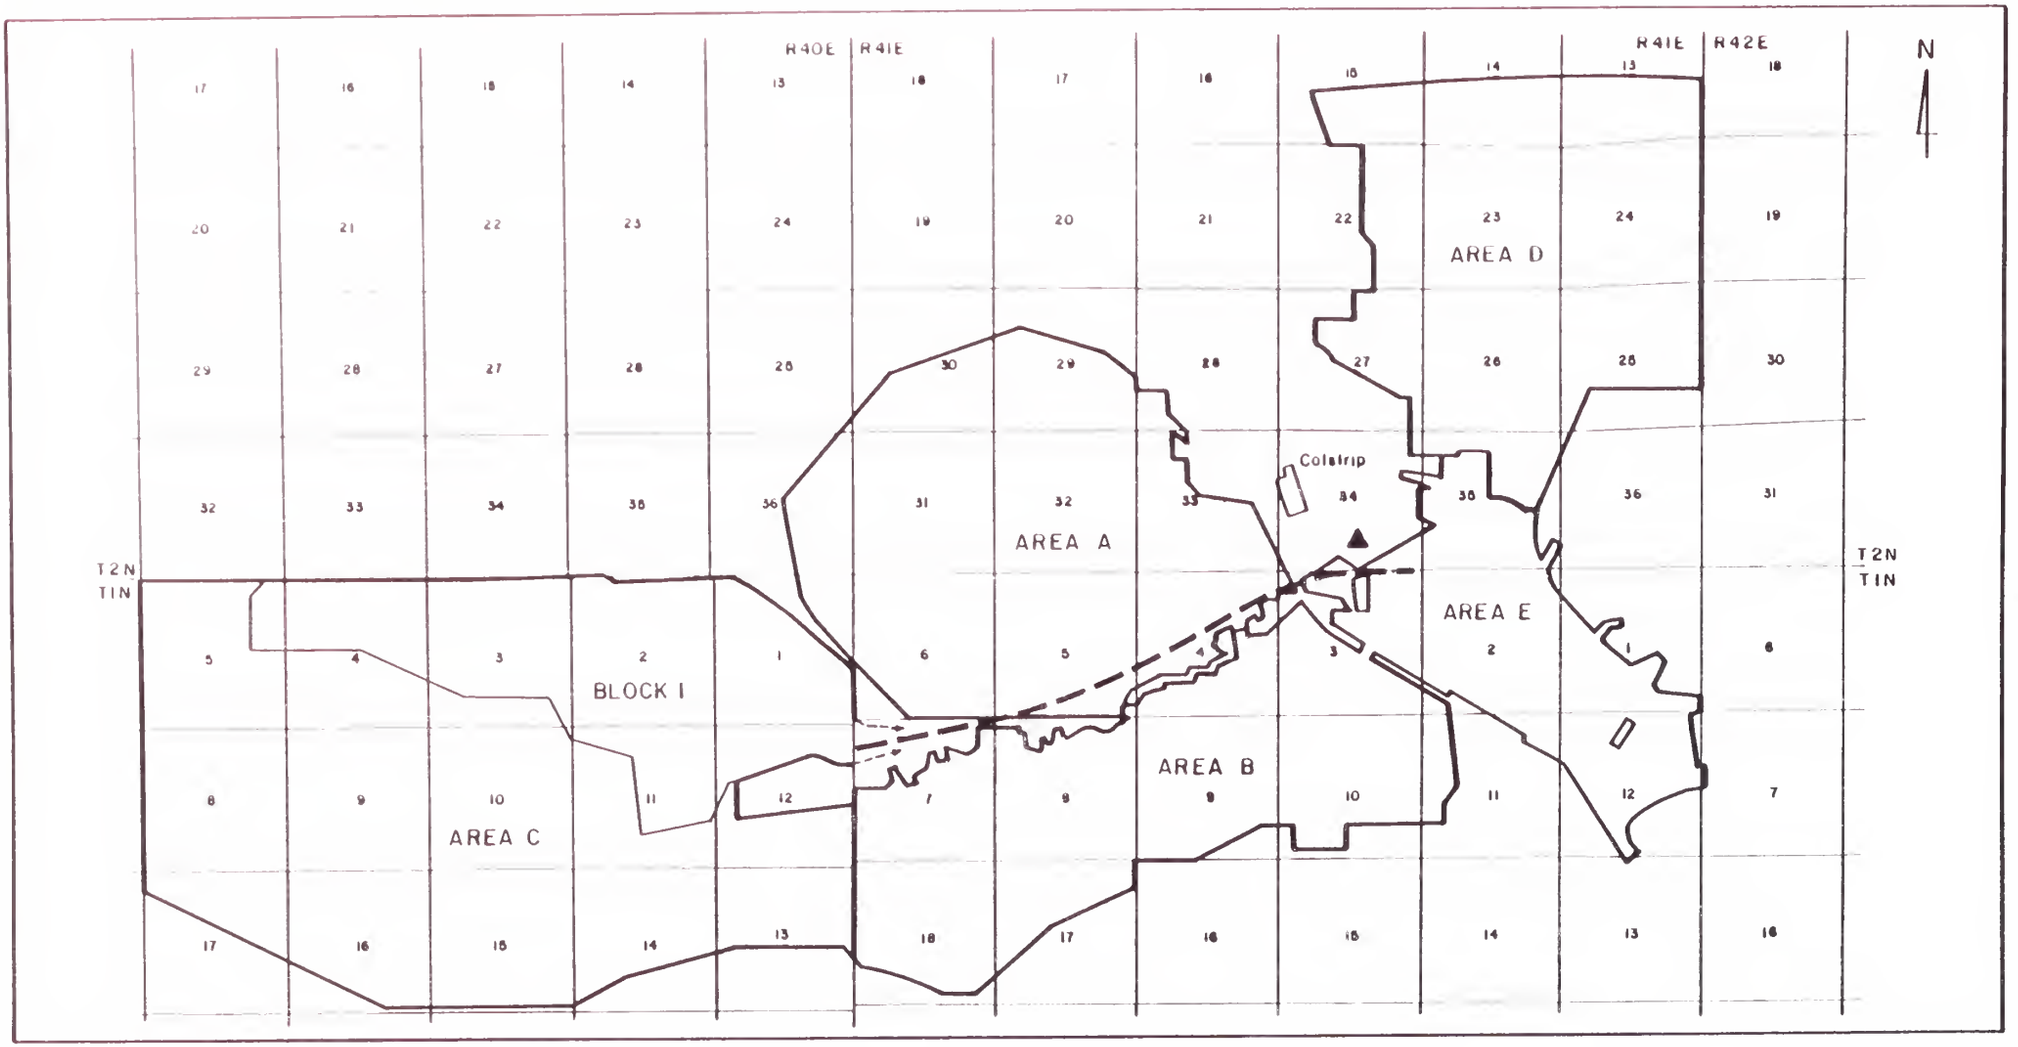
Facilities to be included in the new crusher complex are:

- Fuel storage tanks
- Negative air pressure truck dump
- Primary crusher
- Secondary crusher
- Beginning of an overland conveyor

3. Mining Plan

Western Energy's mine plan is a five-year plan to conduct surface mining operations in Area C, Block I of the Rosebud Mine. Block I is located in Sections 1, 2, 3, 4, 5, 11, and 12 of T1N, R40E and Section 7 of T1N, R41E. The permit area addressed in the mine permit application encompasses 2,693 acres, of which 709 acres are proposed to be mined, and an additional 918 acres are planned to be disturbed as a result of mining-related activities, including a shop complex, crusher complex, haul roads, topsoil storage areas, boxcut, and highwall reduction areas. Approximately 1,066 acres within the permit area will remain undisturbed under this mine plan. Additionally, the conveyor corridor would occupy about 226 acres, running 4.5 miles from the Area C, Block I mining area to Colstrip power generating Units 3 and 4.

It is planned that a total of 23.7 million tons of coal from the Rosebud seam will be mined from Area C, Block I as a dedicated fuel source for Colstrip Units 3 and 4. Western Energy has proposed a typical single pass dragline operation as the optimum method for coal recovery. Extraction of the reserves lying within this mine plan area will be



LEGEND

Exhibit 3

accomplished by the area strip mining method, which is used in all of Western Energy's operations at Rosebud Mine. The maximum production rate will be approximately 5.6 million tons of Rosebud coal per year, which will be attained during the fourth and fifth years of production.

The mine plan calls for developing a boxcut with a dragline along the coal outcrop line (see Year 1 in Figure I-3). The overburden from the boxcut (or first cut) would be placed on an area outside the coal outcrop line directly adjacent to the boxcut. Successive pits would parallel the boxcut, progressing into deeper overburden to the south and northwest through Year 5 as shown in Figure I-3. Overburden from each successive dragline cut would be placed in the previous pit after removal of the coal. As new federal leases become available to Western Energy in Area C, it is intended that an amended mine permit application would be submitted, showing an adjustment to the orientation of the pits, whereby more coal would become available for mining.

Topsoil and subsoil would be stripped in advance of each pass in two separate lifts. The average depth of topsoil stripped will be six to eight inches. Topsoil stripping will be accomplished by scrapers that will strip, transport, and deposit the topsoil on regraded areas or in topsoil storage areas. Crawler tractors will be used as needed to assist the scrapers in loading.

After topsoil has been removed from a sufficient area, subsoil will be removed to an average depth of 2.5 feet. Overburden will be drilled and blasted in preparation for stripping. The rubblized material will then be stripped using a dragline, assisted at times with mobile diesel equipment. This overburden will be cast into the empty pit remaining from the preceding cut after the coal has been removed. Overburden will be regraded to approximate original contour to comply with Montana's Strip and Underground Mine Reclamation Rules and Regulations as soon as adequate working room is available. Regrading will lag behind the mining operation by two spoil ridges during normal operations.

As the Rosebud coal seam is exposed in each pass, the coal will be drilled and blasted, and will then be excavated by loading shovels or mobile diesel equipment. These machines will load the coal into coal haulers, which will transport the coal to the new crusher facility for sizing to three-inch minus. The final product will be loaded onto the new overland conveyors for shipment to Colstrip Units 3 and 4.

The final cut will be backfilled and regraded using crawler tractors and scrapers. Final slopes no greater than 5:1 (20 percent slopes) will be achieved using material from the highwall reduction zone and final spoil ridge. Western Energy uses a 22 percent swell factor in calculating the post-mine topography.

4. Reclamation Plan

To comply with the Montana Strip and Underground Mine Reclamation Act, Western Energy must reclaim and restore all lands disturbed by

mining. Western Energy's proposed reclamation program includes topsoil and subsoil salvaging, backfilling, regrading, highwall reduction, drainage reconstruction, subsoil and topsoil redistribution, revegetation, and monitoring.

Western Energy is committed to a soil sampling program just prior to soil salvaging, in which a majority of the soils will be sampled using a Giddings soil sampler for electrical conductivity and texture. The results will be used to determine topsoil and subsoil salvage depths. As an erosion abatement technique, soils with excessively high sand content will be salvaged separately and placed on slopes of less than ten percent, away from drainage channels.

Prior to mining, soil will be salvaged using scraper haulers to the depths identified and staked during the pre-salvage sampling program. Spoil will be leveled using crawler tractors, and the final spoil surface scarified using bulldozer-mounted ripper bars. Salvaged soil will be hauled to a prepared regraded spoil surface or to a designated stockpile location. After subsoil and topsoil have been placed, the soil will be prepared by chisel plowing and discing using a farm tractor.

Revegetation of disturbed areas will be designed to return the land to livestock grazing and wildlife habitat uses. In a first phase of seeding, forbs, shrubs, and less competitive grasses will be planted using a Brillion seeder. Mulch will be applied on those areas with slopes exceeding ten percent using a modified stakprocessor. After an establishment period of one to three years, competitive cool-season grasses will be interseeded with a rangeland drill into the established first-phase seeding. In addition, patches of sandy soil materials of one acre or less will be seeded to a mixture of warm-season grasses adapted to sandy soils. Where feasible, existing shrubs and trees from areas to be disturbed will be transplanted to bottomlands and scattered upland areas using a tree spade. In addition, nursery-grown shrubs and tree tubelings will be used to reestablish shrub and woodland vegetation types. The areas to receive seedlings and the seed mixes included in Appendix G are shown on Figure I-8.

D. AREA C LIFE OF MINE PLAN

Western Energy has not formally submitted a life of mine plan for Area C beyond Block I to OSM or DSL. Figure I-9 shows the generally anticipated mining sequence and location for all mining in Area C, tentatively identified by Western Energy for comprehensive planning purposes.

Mining under the 34-year life of mine plan would recover approximately 166 million tons of coal (Table I-1). All coal from Area C would be transported to Colstrip generating Units 3 and 4 by the conveyor belt proposed in the Block I plan.

During the Area C life of mine under the Block II plan, coal production would proceed at an average annual rate of 4.9 million tons per

year, resulting in an annual disturbance of approximately 148 acres. A total of approximately 5,040 acres would be mined in 34 years. In addition, about 2,862 acres would be disturbed by facilities, roads, the conveyor system, boxcut spoils, and highwall reduction activities. In Area C, a total of some 7,900 acres would be disturbed. No major facilities in addition to those proposed under the Block I plan would be required.

At any one time, mining and related disturbances would result in as much as one-eighth of the total 7,900 acres having no vegetative cover. This would include the period between initial topsoil salvage and seeding of the replaced soil on the regraded surfaces. Seeding failures caused by drought or other factors could increase the total areas not protected by vegetation.

Exhibit 3

CHAPTER II
DESCRIPTION OF THE EXISTING ENVIRONMENT

A. GEOLOGY

The proposed mine site is located on the gently-dipping northwest flank of the Powder River Basin. Geologic formations that are exposed in the lease area are limited to the Tongue River Member of the Paleocence Fort Union Formation, and Quaternary Alluvium. Other formations in the region and subsurface mine area are described briefly in the columnar section depicted in Figure II-1.

1. Topography/Geomorphology

The Rosebud Mine lies within the unglaciated Missouri Plateau, a division of the Northern Great Plains Physiographic Province (Fenneman, 1931). The topography of this region is described by Keefer (1974) as being characterized by open high hills, with low to moderate relief.

Area C, Block I lies within the drainage basins of East Fork Armells Creek and Stocker Creek, both of which are intermittent streams draining away from the permit area in a northeasterly direction. Stocker Creek empties into East Fork Armells Creek north of the permit area and East Fork Armells Creek runs generally north from there to the Yellowstone River. No other drainages would be affected by the proposed mining activities. The drainage divides of East Fork Armells Creek and Stocker Creek drainage basins are formed by either prominent ridges of sandstone or resistant clinker caprock, or more rounded hills developed on siltstone units. Small ephemeral drainages start from close to these upland crests and drain toward the main channels. Elevations within the Area C, Block I permit area range from 3,440 feet to 3,680 feet.

The landforms in Area C have developed on the essentially flat-lying Tertiary sediments of the Fort Union Formation, and can be divided into five major map units. The characteristics of these units are summarized in Table II-1. Each landscape unit reflects modern processes acting on surficial materials with different geologic and geomorphic histories.

The most stable unit in the permit area is the Sandy Valley Bottom Unit (B_1), which covers 18.9 percent of Area C. The low sediment yields from this unit are a consequence of the high infiltration rates, low drainage densities, and gentle gradients characteristic of this landscape component. The silty residual upland unit (U_2), comprising 49.1 percent of Area C, is the most unstable unit. A moderate volume of runoff and sediment is derived from this unit. The relative unstability of this landscape component is partly a consequence of its geologic history. Incision due to base level lowering has removed any protective surficial deposits, exposing the underlying bedrock. On these residual slopes blanketed by soils with low infiltration capacities, hill slope erosion processes dominate, resulting in increased sediment yields. A dense vegetation cover (40 percent) appears to play an important role in moderating erosion within this unit.

Exhibit 3

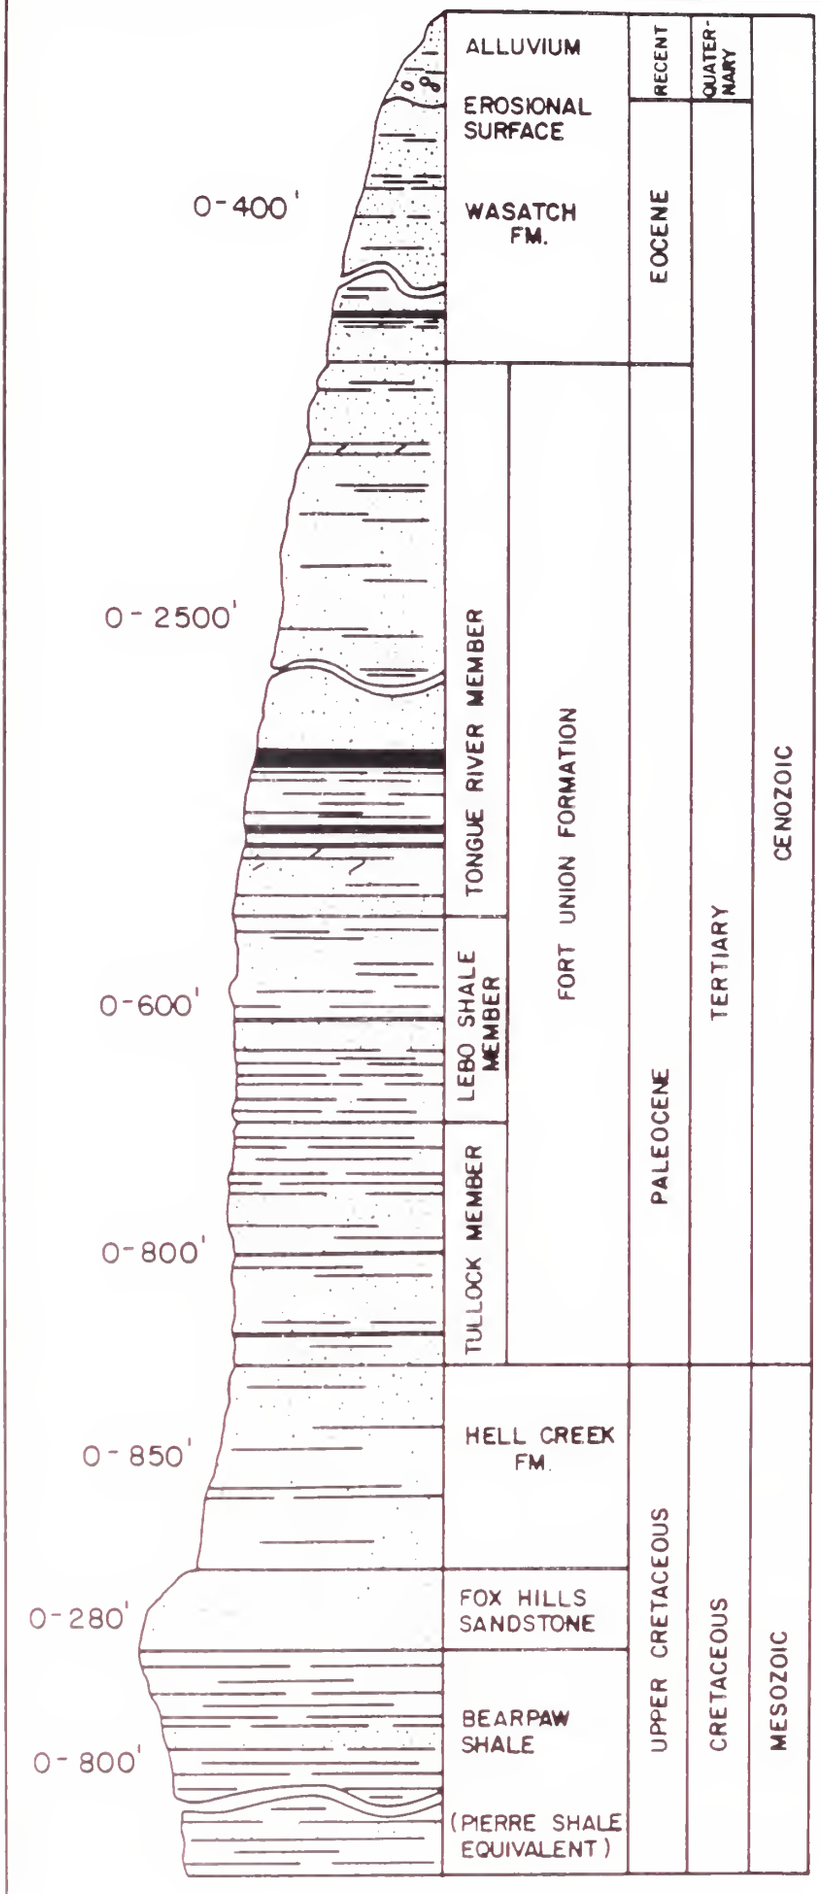

FIGURE II-1

GENERAL COLUMNAR SECTION OF UPPER CRETACEOUS AND CENOZOIC ROCKS IN THE COLSTRIP AREA, NORTHWESTERN POWDER RIVER BASIN, MONTANA
(After Lewis and Roberts, 1978)

ALLUVIUM - Sand, silt, clay, and local gravel lenses and benches.

WASATCH - Brownish-gray to light-gray, fine- to coarse-grained lenticular beds of sandstone and interbedded gray shale and coal. Base of unit is mapped as the top of the thick and persistent Roland coal bed, as defined by Baker (1929). Locally eroded off in the Rosebud Mine permit area.

TONGUE RIVER - Light-yellow to light-gray, fine- to medium-grained thick-bedded to massive locally crossbedded and lenticular sandstone and siltstone; weathers to a buff color. Commonly contains light-buff to light-gray shaly siltstone and shale, and brown to black carbonaceous shale. Contains numerous coal beds. Burning of the coal along outcrops has formed thick red and lavender clinker and baked shale beds. Base of unit is mapped as the change from predominantly siltstone and sandstone to predominantly shale of underlying unit.

LEBO SHALE - Predominantly dark shale containing interbeds of light-gray and brown to black carbonaceous shale, siltstone, and locally thin coal beds. Shales contain altered and devitrified volcanic ash and brown ferruginous concretions. Base of unit mapped as the change from predominantly shale to predominantly fine-grained sandstone and shale of underlying unit. Conformable contact with underlying unit; however the Lebo exists locally as deposits in channels eroded deeply into the underlying Tullock member.

TULLOCK - Lower part of member is interbedded medium-gray to light-gray shale, fine-grained light-gray sandstone and siltstone, and thin but persistent coal beds; grades upward to light-gray carbonaceous shale. Locally at the top is a resistant sandstone that forms a well-developed rimrock. Base of unit is mapped as the change from fine-grain, thin-bedded sandstone, siltstone, shale, and coal beds to predominantly massive channel sandstone and dark-gray shale of underlying unit. (Brown, 1952 and Dunlap, 1958)

HELL CREEK - Shale and siltstone, gray to yellowish-gray, silty, clayey, sandy, carbonaceous, and bentonitic; locally, a yellowish-gray to tan, fine- to medium-grained silty sandstone containing thin coal beds predominates. Lower contact is gradational. Contact probably unconformable with underlying Fox Hills Sandstone or Bearpaw Shale.

FOX HILLS SANDSTONE - Near-shore sand facies that is the uppermost marine deposit in the area. Two members are recognized: Colgate Member -- very light-gray, fine- to medium-grained massive sandstone. Unnamed lower member -- gray to brownish-gray, fine-grained thin-bedded sandstone, interbedded with gray sandy shale and siltstone. Lower contact is gradational, considered to be the base of transition zone between sandstone above and shale of underlying unit. Conformable contact with underlying unit.

BEARPAW SHALE - Gray to black marine shaly claystone and shale. Contains some thin-bedded siltstone and silty sandstone, and locally thin beds of bentonite.

Exhibit 3

The silty valley bottom unit is characterized by a low density of drainage lines (despite low surficial infiltration rates), apparently due to the destruction of channels by cultivation. As a consequence, the existing channel network may be inadequate to conduct runoff from this unit. To adjust, the network will tend to expand by entrenchment, resulting in increased sediment yields. This unit may, therefore, be potentially unstable. Sediment yields from the other landscape units in the permit area are estimated to be low, reflecting high infiltration capacities, resistant surficial materials, and a dense vegetative cover on these components.

East Fork Armells Creek and Stocker Creek both reflect strong bedrock and structural control (by faulting) on drainage basin and stream network development. This influence is strongest in the headwaters of these creeks and decreases downstream. Sediment yield from subbasins of these drainages in Area C is generally low, reflecting the high infiltration rate and the relative inefficiency of the vegetated ephemeral streams in transporting sediment. A discussion of the sedimentation rates and the method of calculation is presented in the Technical Support Document. The main channels within the basins are generally stable, while the smaller, ephemeral channels are less stable.

2. Stratigraphy

Quaternary deposits consist of weathered bedrock, colluvium, and unconsolidated clay, silt, and sand alluvium. In the five-year mine plan area, clinker deposits (locally known as scoria) have formed at and above the burned coal outcrop. Alluvial gravels are present in the East Fork Armells Creek Valley, which lies outside of Area C, Block I. Alluvium, colluvium, and clinker all constitute porous, near-surface aquifers of limited potential volume.

The Wasatch Formation has been removed by erosion in the Rosebud Mine area, and the only rock unit outcropping is the Tongue River Member of the Fort Union Formation. This member is predominantly a fine- to medium-grained silty sandstone with interbedded siltstone, silty shale, carbonaceous shale, localized clinker deposits, and coal beds. Pederson (Western Energy, 1981) states that the total thickness of the Fort Union Formation at Colstrip is 445 feet, with at least the top 360 feet being the Tongue River Member. Three coal seams in this member, in descending stratigraphic order, are the Rosebud, McKay, and Stocker. The coals dip generally one to two degrees southerly, with many local variations in the mine area as a result of small-scale folding, faulting, and localized thinning and thickening of coal seams and interburden.

3. Overburden

The overburden in Area C, Block 1 is composed of interbedded sandstone, siltstone, shale, and clinker, with various degrees of gradation between the units. Geochemical analyses of samples collected from drill holes in the overburden are presented in table form in Western Energy Company's Mining Permit Application for Area C, Block I, and in computer

printout form in the Technical Support Document for this EIS. The location of overburden test holes in Area C, Block I is shown in Figure II-2.

The overburden material was tested for 18 parameters (Western Energy Company, Mine Permit Application Area C, Block I, 1981); however, only seven of the 18 parameters tested showed significant values exceeding DSL suspect levels: electrical conductivity, molybdenum, cadmium, lead, nickel, zinc, and sand (See Appendix A, Table 1, for description of DSL suspect levels).

Because of the widespread contamination of samples by zinc- and lead-based drilling pipe joint grease, the anamalous lead and zinc values in the overburden have not been considered valid in this study. The remaining five parameters are shown graphically in Table II-2 by percentage of samples in each overburden hole that exceed state suspect level.

As Dollhopf et al. (1977, 1978, 1979) reported in their studies on the eastern part of Area B, the trace metals have a generally greater affinity for shale in the overburden than for other lithologies. In Area C this is particularly true of the shale immediately overlying the Rosebud coal seam.

4. Aquifers

Aquifers in the mine area include alluvial and colluvial deposits, Tongue River Member sandstones and coals, Lower Fort Union sandstones, and the lower Hell Creek-Fox Hills Sandstone (considered a single aquifer). In the mine area, only those aquifers above the McKay coal seam would be physically disturbed. A baseline description of these aquifers is presented in Section B, Hydrology.

5. Structure

The proposed mine area lies entirely within the northwestern portion of the Powder River Basin, a large depositional basin extending east into South Dakota, southward into Wyoming, and over thirty miles west and north from Colstrip. Superimposed upon this northwest flank of the Powder River Basin are numerous smaller scale structures, including the Ashland Syncline, a west-northwest trending shallow structural trough that cuts the southwest quarter of T1N, R40E. The axis of this syncline roughly coincides with the southwestern limit of proposed mining as shown in Western Energy Company's Comprehensive Mine Plan, Exhibit C (1981) (see Surficial Geology Map in the Technical Support Document).

Local doming, rolls, and minor folds are indicated in the Area C, Block I structural contour maps (Western Energy, Mine Permit Application, Area C, Block I, Volume 7, Exhibits T and U). No faults have previously been mapped in Area C, Block I, but in other sectors of the Rosebud Mine several faults have been mapped and/or inferred from aerial photos.

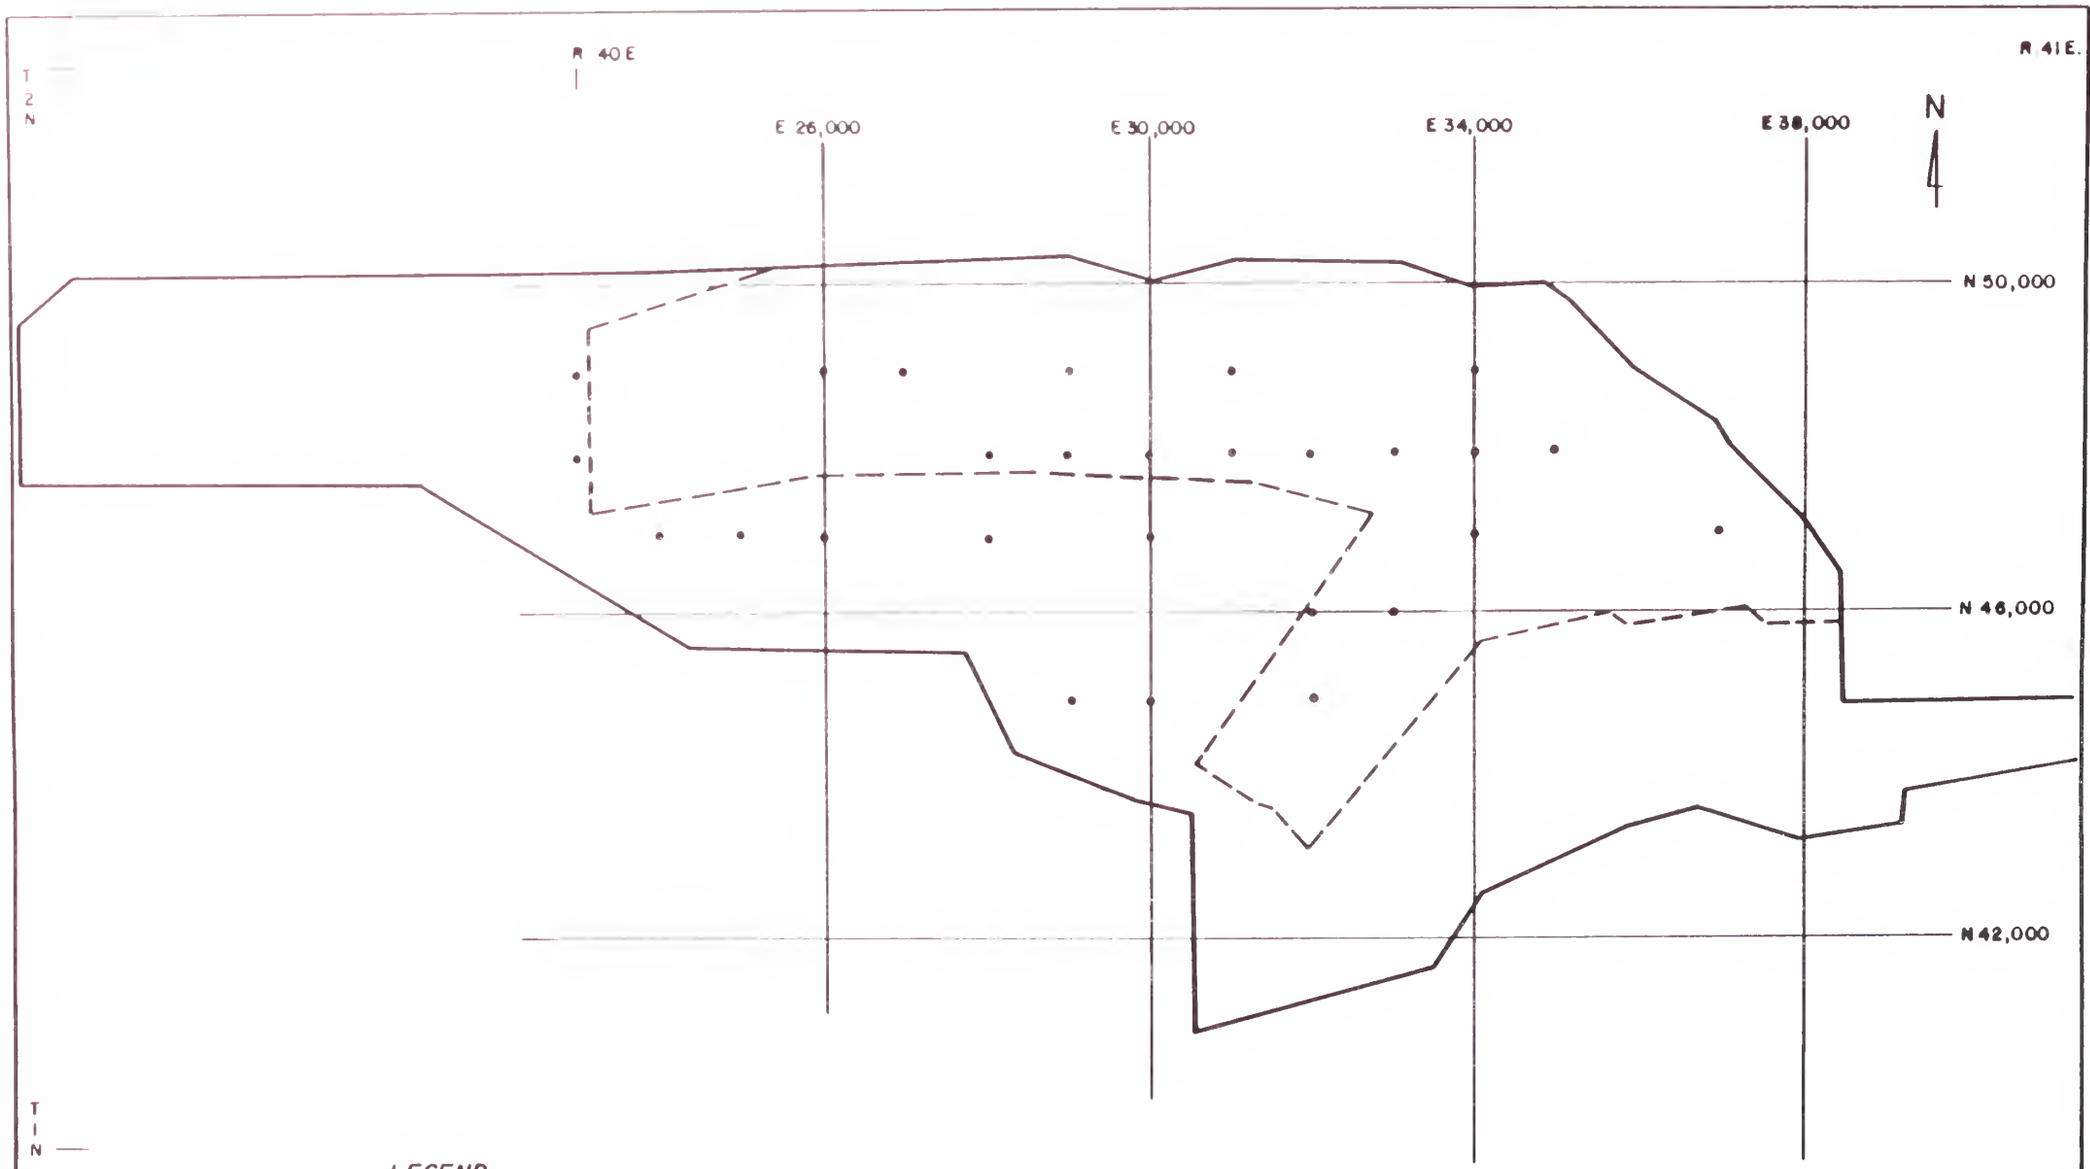

FIGURE II-2 OVERBURDEN GEOCHEMISTRY HOLE LOCATIONS
ROSEBUD MINE, MONTANA

Exhibit 3

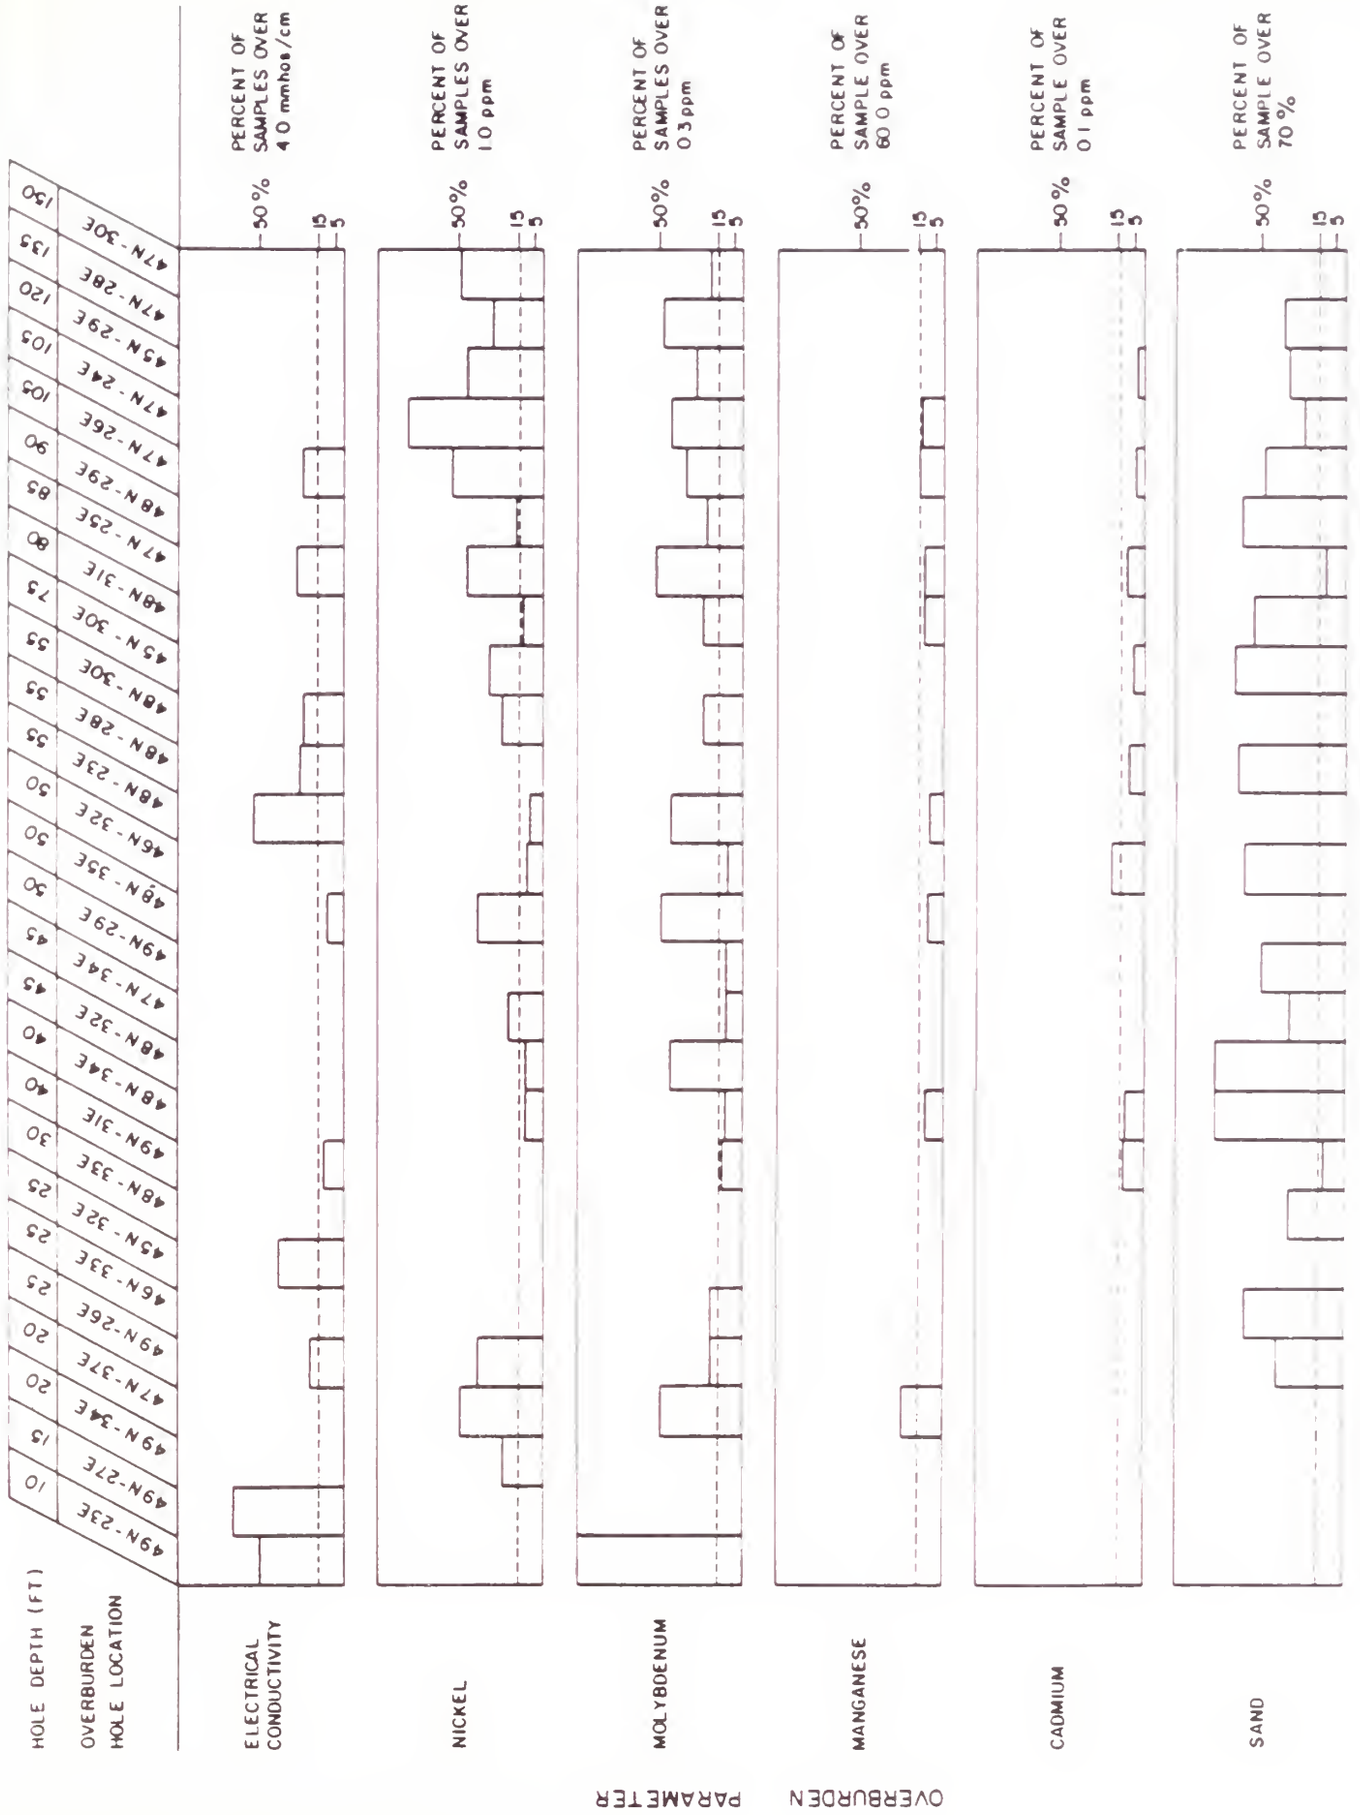

TABLE II-2 PERCENTAGE OF SAMPLES EXCEEDING STATE SUSPECT LEVELS IN OVERBURDEN TEST HOLES, AREA C, BLOCK I
ROSEBUD MINE, MONTANA

Exhibit 3

These faults have a strong west-northwest trend paralleling the Ashland Syncline axis.

Based on geologic cross sections from Western Energy's Area C, Block I Permit Application (Volume 7, Exhibit W) and topographic and air photo interpretation, a fault zone with at least two apparent faults is inferred in Area C, Block I. This zone trends northwest-southeast approximately through the northwest corner of Section 11 and halfway across Section 3, T1N, R40E. On cross section 46,000 N (Exhibit W) the northeastern-most inferred fault has a maximum displacement of greater than 70 feet down to the southwest. On cross section 29,000 E (Exhibit W) the southwestern-most inferred fault has a maximum displacement of 60 feet up to the southwest. It appears likely, from the evidence in the Exhibit W cross sections and topographic coincidence of linear features with anomalous dip changes in the sections, that some additional faulting along northwest-trending structures would be encountered in mining Block I. The same evidence suggests that such faults, if present, would likely have a displacement of less than 30 feet.

6. Geologic Hazards

There are no known significant geologic hazards in the proposed mine area. No active faulting is evident and the entire northern portion of the Powder River Basin is a tectonically stable area.

7. Paleontology

Fossil leaves and invertebrates of the Paleocene Period occur fairly abundantly throughout the Fort Union Formation and are likely to be encountered at the proposed mine. However, these are all common fossils and have limited scientific significance. No significant vertebrate fossils are known to occur in the Fort Union Formation (Taylor, 1975; U.S.D.I., 1978). There are no known fossil collecting sites in the mine permit area.

8. Resources

Natural resources occurring in the Northern Powder River Basin include coal, oil, gas, uranium, sand, gravel, and some clay. Of these, the coal resources are by far the most important.

Oil and gas exploration is currently active in Rosebud County, but no discoveries of oil or gas have been found in the area of the Rosebud Mine. No oil or gas wells have been drilled in Area C. The nearest oil and gas production to the mine area is in the Hardin field approximately 36 miles to the west, where gas is produced from the Mid-Cretaceous Frontier Formation. The nearest oil production to Colstrip is 48 miles north on the Porcupine Dome.

There are no known or indicated reserves of uranium in the Rosebud Mine area. Sand, gravel, and some clay are present in minor amounts.

Clinker deposits along the burned coal outcrop have been used for road gravel in the past.

Coal resources in Area C, Block I consist of the Rosebud, McKay, and Stocker seams, in descending stratigraphic order. The Rosebud seam is the primary coal seam of interest at the Rosebud Mine, and would be the only seam mined at Area C, Block I. Total in-place reserves in the Rosebud seam (Block 1) are approximately 27 million tons, of which Western Energy estimates 23.7 million tons recoverable in the Area C, Block I first five-year mine plan (see Table I-1). The Rosebud coal in Area C averages 8,348 Btu per pound and 0.86 percent sulfur (as received, proximate analyses).

The McKay coal seam lies below the Rosebud seam at an average interburden depth of 23 feet in Area C, Block I. The McKay averages eight feet thick, yielding approximately 9.6 million tons in place (calculated at 1,700 tons per acre-foot). Western Energy does not plan to mine the McKay coal for several reasons, which are discussed in depth in Chapters I and IV of this EIS. McKay coal in Area C averages 8,348 Btu per pound and 1.31 percent sulfur (as received, proximate analyses).

The Stocker seam lies between eight and nine feet below the McKay seam over most of Area C, Block I. This coal is of lower Btu value and higher sulfur content than the McKay seam. Average, as-received proximate values for 15 samples of the Stocker coal in Area C (Western Energy, analyses reports) yielded an average of 7,469 Btu per pound and 1.76 percent sulfur and exhibited an average thickness of 4.44 feet.

B. HYDROLOGY

The following section discusses groundwater and surface water systems, on both a regional scale and on a more localized scale (Area C, Block I). The regional data considered within this section is specific to the area of influence surrounding the existing Rosebud Mine, near the townsite of Colstrip. The general hydrologic setting within the study area is depicted on Figure II-3. The figure also illustrates the surface water drainage networks and coal seam outcrops*/subcrops* that have been examined during the preparation of this EIS.

The purposes of this section are to identify flow characteristics, describe the existing quality and usage for both surface and groundwater systems, and also to identify the relationship between surface and groundwater throughout the hydrologic study area. Regional and site-specific characteristics of Area C, Block I will be discussed under each of the major topical headings, particularly when site-specific characteristics deviate from the regional characteristics.

Primary information on the hydrology of the Rosebud Mine area was obtained from site-specific reports completed in the past ten years. Western Energy's data base includes information on groundwater, surface water, and water quality. Data was also obtained from published reports and ongoing studies on the general hydrology of the area prepared by The Montana Bureau of Mines and Geology, United States Geological Survey (USGS), and the U.S. Environmental Protection Agency (EPA). In addition, existing regional and site-specific Environmental Impact Statements (EIS), Montana Power Company special reports, state documents, Peabody Coal Company's data base, and Montana State University Agricultural Experiment Station research documents were also used.

1. Groundwater

The discussion on groundwater includes:

- The physical and hydraulic properties of each water-bearing unit
- The characteristics of groundwater flow in each unit aquifer
- Groundwater quality
- Groundwater use

In some instances, the characteristics of Area C, Block I are different from the hydrologic study area as a whole. Appropriate comparisons are made in these instances.

a. Water-bearing Strata

Groundwater and geologic studies (Section A.2) have identified seven near-surface geologic units within the Rosebud Mine area that can store and transmit water (Figure II-4). The water-bearing strata are (from youngest to oldest):

* Indicates the first appearance of a term defined in the Hydrology Glossary

Sub-McKay
Rosebud Overburden
Rosebud Coal
Valley-Fill-McKay Coal

The following is a description of the physical and hydraulic properties for each of these water-bearing units. The discussion relates to the hydrologic study area in general (Figure II-3), except as qualified by site-specific references in the text. Sub-section 8, entitled "Area C Characteristics" describes properties that are specific to Area C. In general, however, the properties identified for each water-bearing unit are considered to beconsistent throughout the hydrologic study area.

1) Rosebud Spoils

The Rosebud spoils consist of reworked Rosebud coal overburden material, which has been replaced where the Rosebud coal has been mined out.

Since the dragline operation deposits spoils parallel to the stripping operation, spoils exhibit higher permeability* coincident with the direction of the dragline movement. Due to the linear nature of the spoils, permeability* values also vary directionally. Data from aquifer* tests in the spoils indicate that the mean transmissivity* of the spoils is 2,000 gallons/day/ft, the median transmissivity value of 61 gpd/ft, and a range of transmissivity values from <1 to 23,400 gpd/ft (see Table II-3).

Rosebud spoils in previously mined areas vary in thickness from less than one foot near the coal outcrop to over 120 feet in Rosebud Mine Areas A and B. A more permeable rubble zone has been noted (Van Voast et al., 1978) at the base of the spoils. This zone consists of waste coal and larger rock fragments that roll to the bottom of the spoils during stripping. According to Van Voast et al. (1978), the rubble of boulders and wasted coal at the base of the spoils is probably responsible for the large range of transmissivity values. Generally, however, Van Voast found that hydraulic conductivity* values for the spoils were similar to the hydraulic conductivity values of the aquifers they replaced.

2) Valley Fill Material

The materials comprising the valley fill system consist of alluvial* and colluvial* deposits. These deposits consist of interbedded silts,

sands, gravels, and clays and are generally less than 40 feet thick. In the Rosebud Mine area valley fill material is found in stream bottoms and on terraces*, which are situated approximately 10 to 20 feet above the stream bottoms. Colluvial and alluvial material intermingle where the hillsides merge with the alluvial terraces, and are often difficult to differentiate.

The large range of particle sizes, from boulder-sized colluvial fragments to clay-sized particles in the alluvial deposits, along with the lenticular nature of the valley fill deposits has an effect on the direction of groundwater flow in this system. These lenses of alluvial material in the valley fill system result in zones of variable hydraulic conductivity. Table II-3 lists the available transmissivity and hydraulic conductivity values for the wells tested in the study area. Most of the valley fill aquifer tests were performed along East Fork Armells and Stocker Creek drainages.

Botz (1979) and Van Voast (1977) state that storage coefficients ranging from 0.1 to 0.3 are typical for the valley fill material. Transmissivities for the East Fork Armells Creek valley fill range from 6 to 74,800 gpd/ft for 29 tests. The mean and median transmissivity values are both approximately 10,000 gpd/ft.

The Valley fill material in Stocker Creek appears to consist of the same material present in East Fork Armells Creek, but exhibits a narrower range of transmissivity values (2,200 to 50,000 gpd/ft). Only six aquifer tests have been conducted in the Stocker Creek drainage. It should be noted that the mean and median values for transmissivity and hydraulic conductivity (Table II-3) are highest for the valley fill aquifer, as compared to the other water-bearing strata underlying the area. This is due to the coarse-grained nature of some of the valley fill materials.

3) Rosebud Coal Overburden

Rosebud overburden is found throughout the area overlying the Rosebud coal, and is composed of brown to gray, very fine- to medium-grained sand, shale, claystone, and clinker*. Overburden thickness varies from zero at the Rosebud coal outcrop/subcrop to over 240 feet beneath the sandstone ridges in Area C. The sandstone, shale, and claystone are interbedded and discontinuous, so that the ability of the aquifer to transmit water is variable from well to well.

The overburden is generally considered to be an unconfined* aquifer, although in some areas it does show confined* characteristics. Twenty-two aquifer tests conducted in the Rosebud overburden indicated a range of transmissivity values from 1 to 79,000 gpd/ft. The mean (8,950 gpd/ft) and median (57 gpd/ft) values vary by approximately 8,900 gpd/ft. This wide variation in transmissivity may be due to the discontinuity of the lithologic units in the overburden (Geology, Section A.3). Faults

TABLE II-3

SUMMARY OF TRANSMISSIVITY AND HYDRAULIC CONDUCTIVITY VALUES
FOR AQUIFER TESTS IN THE ROSEBUD MINE AREA

	TRANSMISSIVITY				HYDRAULIC CONDUCTIVITY

(b) Interburden - Rosebud coal overlies the McKay coal unit.

Exhibit 3

and fracturing in the overburden in Area B (Plate B-1, Technical Support Document) could be responsible for the high transmissivity values (79,000 gpd/ft) in that area.

An overburden aquifer pumping test was performed at well WX-101, 2-1/2 miles southwest of Colstrip along East Fork Armells Creek (Figure II-5), where data from four observation wells were analyzed. Storage coefficients ranging from 0.006 to 0.03 were calculated from this test and indicate that in this area the overburden shows confined to semi-confined* conditions. The mean (0.468 ft/day) and median (0.015 ft/day) hydraulic conductivity values indicate a very low rate of flow through the aquifer. Recovery data on both the pumped well and observation wells indicate that there is a lower permeability boundary* or an absence of recharge in the vicinity of the well, since the transmissivity values decrease from 45,000 gpd/ft to 8,000 gpd/ft between 10 and 30 hours after pumping has ended.

In some areas, the overburden includes clinker, which is usually brittle and highly fractured. According to Dollhopf (1978), fractures in the clinker create potential areas of groundwater recharge or discharge.

4) Rosebud Coal

The Rosebud coal varies in thickness from zero at the outcrop to approximately 24 feet, and has an average thickness of 22 feet. The coal is locally fractured and folded, resulting in an increase in porosity* and permeability.

The Rosebud coal aquifer is confined over most of the mine area, except where it crops out or subcrops, along parts of East Fork Armells Creek and the eastern drainages. A broad range of transmissivity values has been calculated for the Rosebud coal. The results of 37 tests range from 3 to 12,700 gpd/ft. The mean transmissivity is 526 gpd/ft, and the median value is 30 gpd/ft. The wide range is probably the result of the inconsistent fracture pattern that is characteristic of the coal bed. The ability of the aquifer to transmit water is directly proportional to the degree of fracturing in the coal.

A constant discharge test of the Rosebud coal aquifer was conducted at well 34-R, one mile south of Colstrip (Figure II-5), where two observation wells were monitored. The storage coefficient was calculated to be about 0.000015, which is within the typical range of 0.00001 to 0.001 for confined aquifers. One observation well, completed in overburden material, was not affected by the drawdown test at the pumped well, indicating that the two aquifers are not connected in that area.

5) Rosebud/McKay Interburden

The Rosebud and McKay coal seams are separated by 10 to 100 feet of interburden. The average interburden thickness varies from 40 to 60 feet in the Rosebud Mine area and consists of clays and shales that act as confining layers. The interburden contains more clay than the overburden and is considered to be a less productive water-bearing stratum.

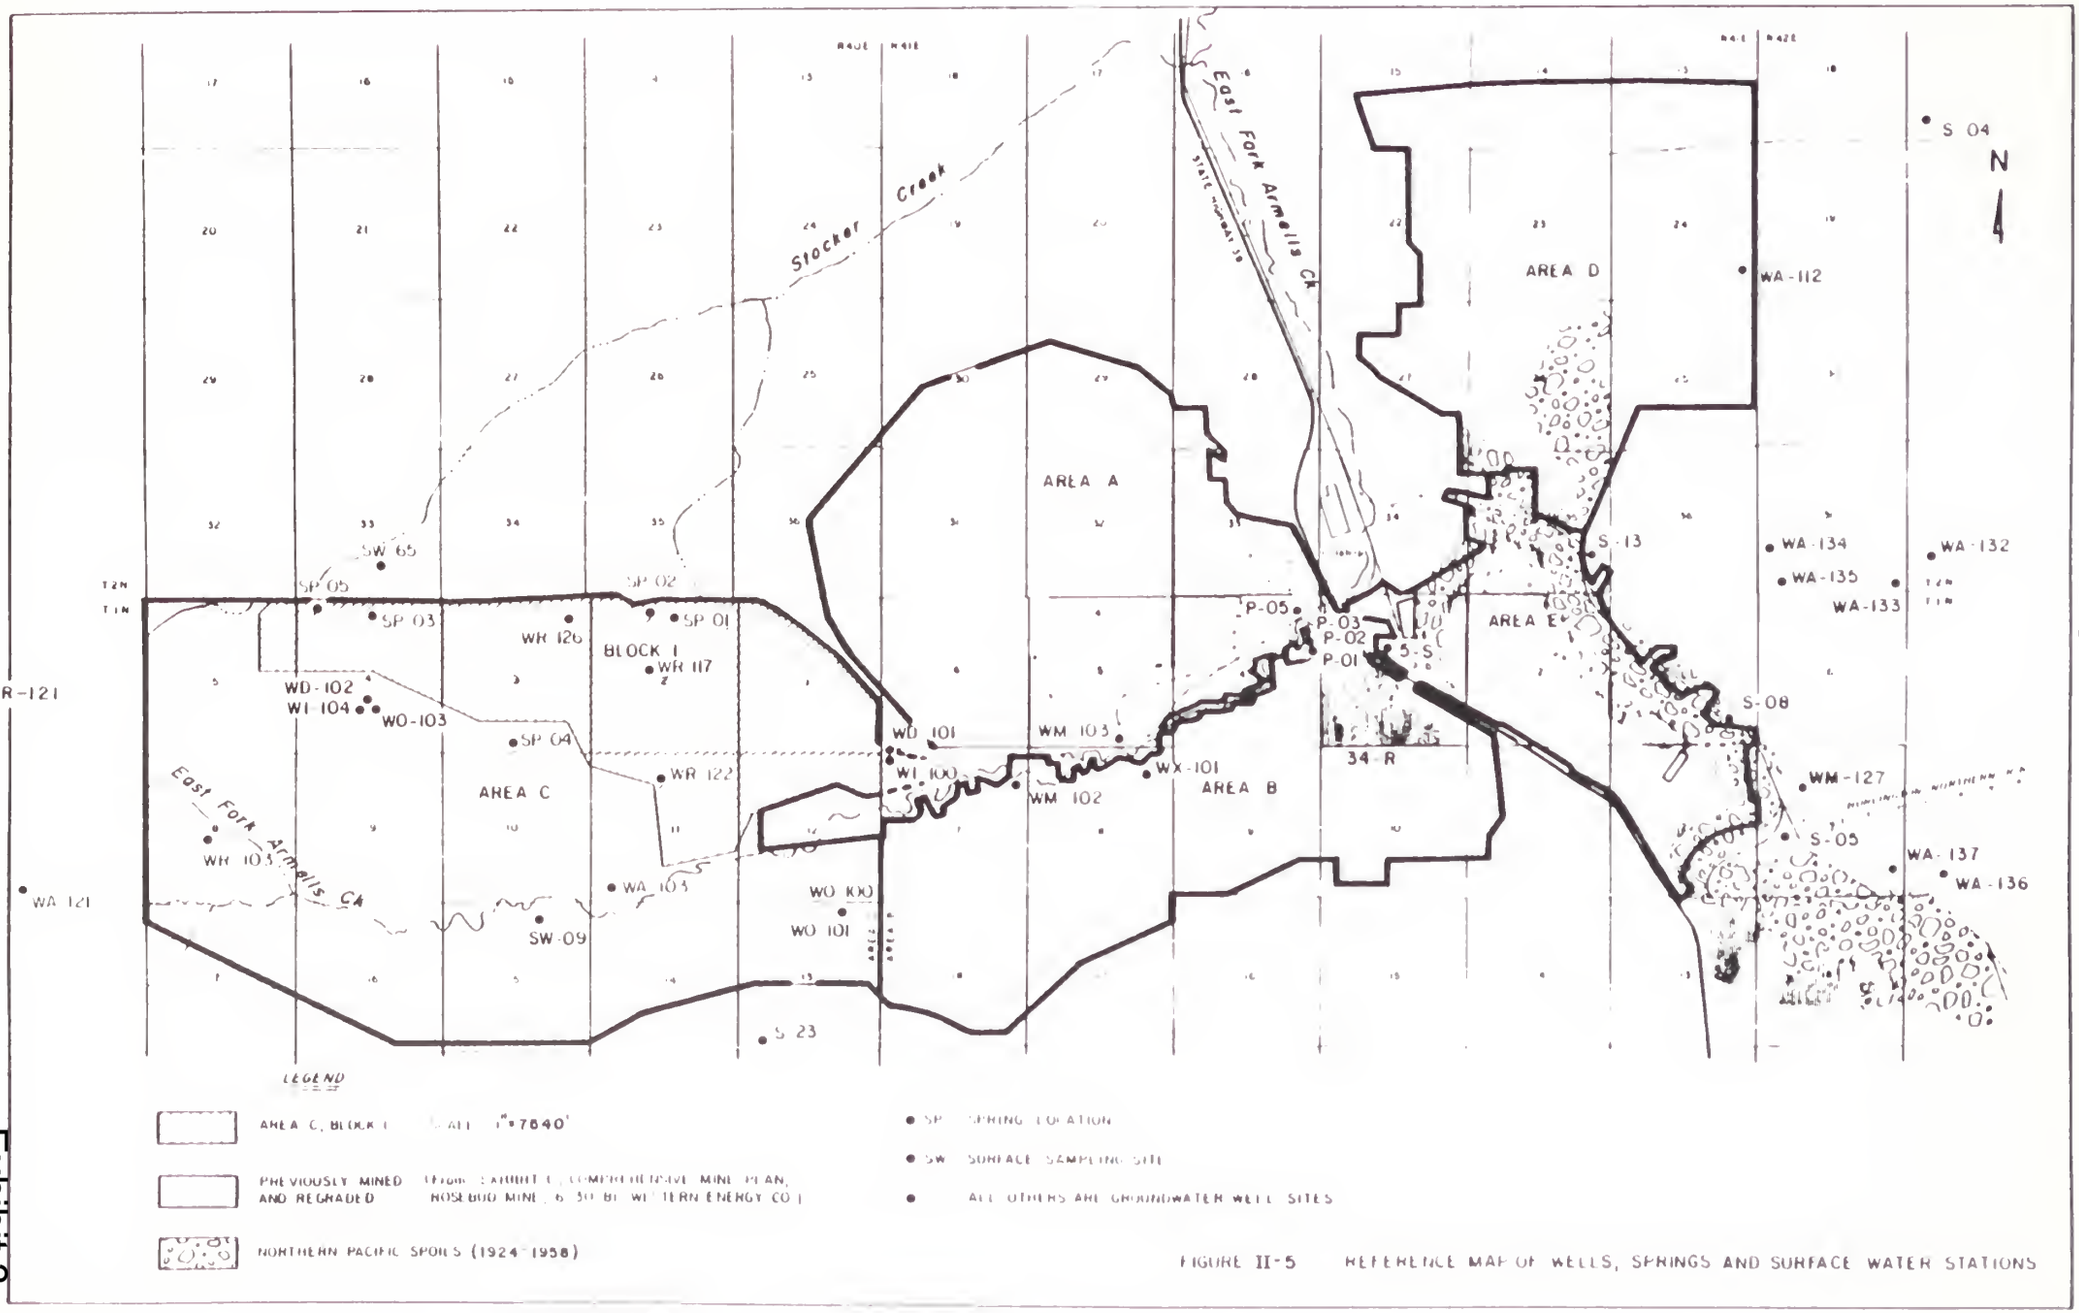

FIGURE II-5 REFERENCE MAP OF WELLS, SPRINGS AND SURFACE WATER STATIONS

Exhibit 3

However, fractures and lithologic changes in the interburden may allow some exchange of groundwater between the Rosebud and McKay aquifers in some areas.

The interburden between Rosebud and McKay coal seams exhibits a mean transmissivity of 43 gpd/ft, and a median transmissivity value of 7 gpd/ft. The range of transmissivity values (1 to 210 gpd/ft) is the lowest for any of the aquifers. Some fractures and faulting have caused anomalously high transmissivity values, but as a unit it appears that the clays and shales characteristic of the interburden are responsible for inhibiting the groundwater flow through this aquifer.

Lithologically, the McKay overburden and the interburden are similar, but, in areas where the Rosebud coal has been eroded (refer to Figure II-4), the material above the McKay coal exhibits the characteristics of an unconfined aquifer*. Transmissivity values for the McKay overburden range from 230 to 2,600 gpd/ft, with a mean of 570 gpd/ft and median of 1,500 gpd/ft. These values are higher than those for the interburden, indicating a difference in hydrologic characteristics between these two units.

6) McKay Coal

The McKay coal is approximately 8 to 12 feet thick in the Colstrip area and exists over most of the area shown on Figure II-3.

The McKay coal is a confined aquifer in the Rosebud Mine area and its porosity and permeability are related to fracturing in the coal seam. According to Van Voast (1977), storage coefficients for both the Rosebud and McKay aquifers are within the same range (0.00001 - 0.0001). However, the transmissivity of the McKay coal aquifer ranges from 1 to 560 gpd/ft (24 tests), which is considerably lower than the range of values for the Rosebud coal aquifer. This is due to the fact that the McKay coal is thinner than the Rosebud coal (transmissivity is a function of thickness). Assuming that the Rosebud and McKay aquifers have equivalent hydraulic conductivities, the thicker Rosebud coal aquifer can transmit more water per unit width than the McKay coal.

7) Sub-McKay

The regional sub-McKay aquifer consists of sandstone and sandy clays in the Tongue River Member of the Fort Union Formation. The sub-McKay unit underlies the McKay coal and ranges from 20 to 250 feet beneath the surface in the Rosebud Mine area. The Lebo Shale Member of the Fort Union Formation forms an areally extensive impermeable base to the sub-McKay unit.

Available information indicates that the sub-McKay is a confined aquifer system; however, very little hydraulic data exists for the aquifer. Transmissivity values from six aquifer tests in the sub-McKay range from 90 to 3,200 gpd/ft and have a mean and median of 860 and 470 gpd/ft, respectively.

8) Area C Characteristics

The physical properties of the water-bearing strata are generally the same throughout the hydrologic study area, including Area C. However, the average Rosebud/McKay interburden thickness is approximately 20 feet greater in Area C than the average for the whole area. Also, because of the existence of sandstone ridges the overburden is up to 240 feet thick in Area C, which is about 90 feet thicker than anywhere else in the Rosebud Mine.

Specifically, ten aquifer tests were performed in the valley fill material, three in the overburden, eight in the Rosebud coal, one in the interburden, one in the McKay coal, and no tests were performed in the sub-McKay coal (see Plate B-1, Technical Support Document, for locations of tests).

The mean calculated hydraulic conductivity for Area C valley fill is 104 ft/day. This compares favorably with the calculated mean hydraulic conductivity of 119 ft/day for East Fork Armells valley fill in the hydrologic study area.

The mean hydraulic conductivity for the Area C overburden is 0.4 ft/day; however, not enough data exists to statistically compare test results with the hydraulic characteristics of the hydrologic study area.

The average transmissivity of the Rosebud coal in Area C is 190 gpd/ft. This is lower than the average transmissivity for the hydrologic study area. There is no apparent reason for this difference; it may be due to natural lithologic variations within the coal.

The McKay coal and Rosebud/McKay interburden Area C hydraulic characteristics cannot be compared to the hydrologic study area test results because only one aquifer test was performed in each aquifer in Area C.

b. Groundwater Flow

The following section will discuss the nature of groundwater flow in the hydrologic study area and, more specifically, Area C. Flow will be defined by: 1) focusing upon the direction of flow within each water-bearing stratum; 2) identifying the way in which significant quantities of water move between aquifers; 3) discussing where and how groundwater recharge and discharge occur; and 4) discussing which aspects of flow in Area C are most significant, as compared with the hydrologic study area in general.

First, before proceding with the discussions outlined above, there are some important overall trends in groundwater flow that should be summarized briefly to provide the reader with a general introduction to groundwater flow systems in the Rosebud Mine area.

- The most significant bedrock groundwater flow exists in the Rosebud and McKay coal seams. Flow velocities are not large,

but they have a higher relative conductivity than the Rosebud overburden or Rosebud/McKay interburden units.

- Bedrock flow generally follows the south-southeast structural gradient of about one-half percent. Deviations in regional flow patterns occur in the vicinity of mine pits, in areas of structural highs and lows, and where coal seams crop out and subcrop.

- A local recharge area appears to be located in Area C. This conclusion is based not so much on the equipotential map, which is inconclusive, but more on geologic and structural evidence.
- Some bedrock discharge occurs along upper East Fork Armells Creek although just above Colstrip the situation reverses and the valley fill along East Fork Armells Creek recharges bedrock.

- Flow in spoil and valley fill originates either by direct infiltration of precipitation or by inflow from bedrock.

- Flow directions in spoils are highly dependent upon the placement of spoil and can't be easily generalized.

- Flow direction in valley fill is generally parallel to the direction of the stream channel.

- Minor deviations in flow direction in valley fill material result from the recharge-discharge relationship with bedrock aquifers; the seasonally controlled amount of net infiltration (from precipitation); and an influx of water to the valley fill from a leaking surge pond downstream of Colstrip.

1) Nature of Flow Within Water-Bearing Strata

The seven water-bearing strata have varying types of flow (i.e., confined and unconfined) and also have varying flow directions. Generally, aquifers of regional extent, such as the Rosebud coal aquifer, show regional flow directions from the northwest to southeast. However, less extensive strata (such as spoils, valley fill, and to some extent the Rosebud coal overburden) tend to have a less uniform flow direction.

The following discussion summarizes flow characteristics in each of the seven water-bearing strata.

a) Rosebud Spoils

The inflow and outflow of spoils groundwater is illustrated schematically in Figure II-4. The groundwater in the spoils is generally unconfined; however, it should also be noted that there is evidence to suggest that water may be confined in the lower portion of the spoils unit.

Figure II-6 is a potentiometric map of the Rosebud Spoils aquifer which clearly shows the lack of uniformity of flow within the spoils.

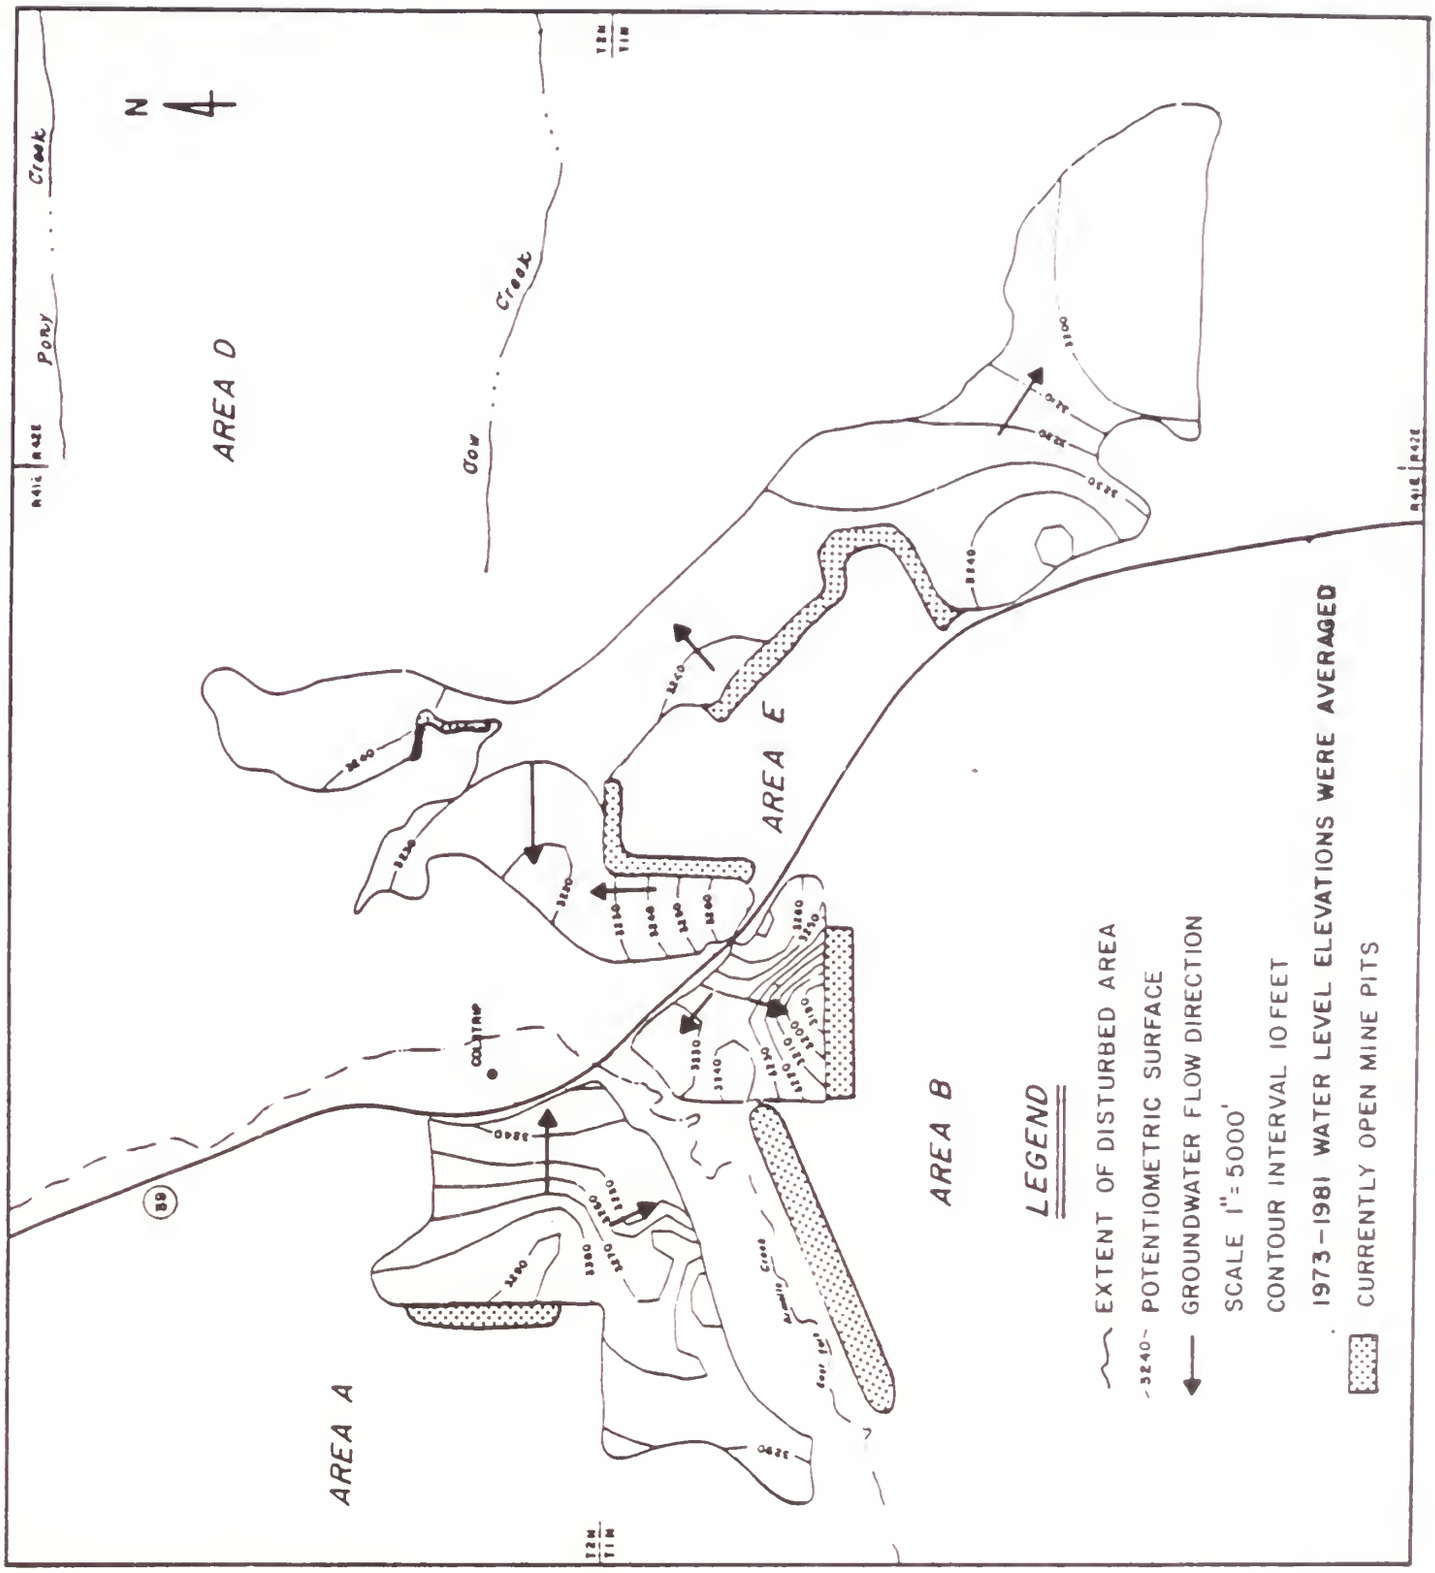

FIGURE II-6 POTENTIOMETRIC SURFACE OF SPOILS AQUIFER, ROSEBUD MINE, MONTANA

Exhibit 3

The following variations in flow direction occur within the Rosebud spoils:

- Where the Rosebud spoils abut a bedrock face left from mining, and overlie the McKay overburden, groundwater flows laterally from the Rosebud overburden and Rosebud coal into the spoils and perhaps vertically into the McKay overburden.

- Where Rosebud spoils are located adjacent to other valley fill material, they are along portions of East Fork Armells Creek, spoils water may originate from bedrock discharge to the spoils or from direct infiltration.

- Where Rosebud spoils become part of the valley fill groundwater flow system, spoils water migrates laterally into valley fill.

b) Valley Fill Material

Groundwater flow in the valley fill system generally parallels the stream channel, as indicated on Figure II-7. This general relationship seems to hold true not only along East Fork Armells Creek and Stocker Creek but also for smaller valley fill systems that are tributary to East Fork Armells Creek. Review of the static water levels demonstrate that water levels and, to an extent, the direction of flow in the valley fill, depend upon net infiltration of precipitation. This relationship, discussed in more detail in Section 3 (Hydrology), shows that water levels decline in summer when evapotranspiration is high and precipitation is low. During winter months, when evapotranspiration is minimal, water levels tend to rise. When water levels rise in winter, equipotentials are deflected toward the stream because the channel has a more significant dewatering effect on valley fill when groundwater levels are higher.

The direction of flow within valley fill is also affected somewhat by whether valley fill is receiving bedrock discharge (as in the upper reaches) or is recharging the bedrock (as in the lower reaches, see Section 1.b.2). Because the valley fill permeabilities are so much higher than those of bedrock strata this discharge-recharge relationship doesn't greatly affect valley fill groundwater equipotentials.

c) Rosebud Coal Overburden

The large variability in overburden lithology makes it difficult to construct an accurate potentiometric map for the overburden. It appears that the general gradient of water in the overburden follows the structural gradient of 0.5 to 1 percent to the southeast. Groundwater is not laterally continuous throughout the overburden, but where there is a saturated condition, the groundwater may be either confined or unconfined. The source of water in the overburden is probably direct infiltration of precipitation, but may also be due to upward leakage from the Rosebud coal. Limited seepage may occur at locations where the overburden has been truncated by mining or where it crops out.

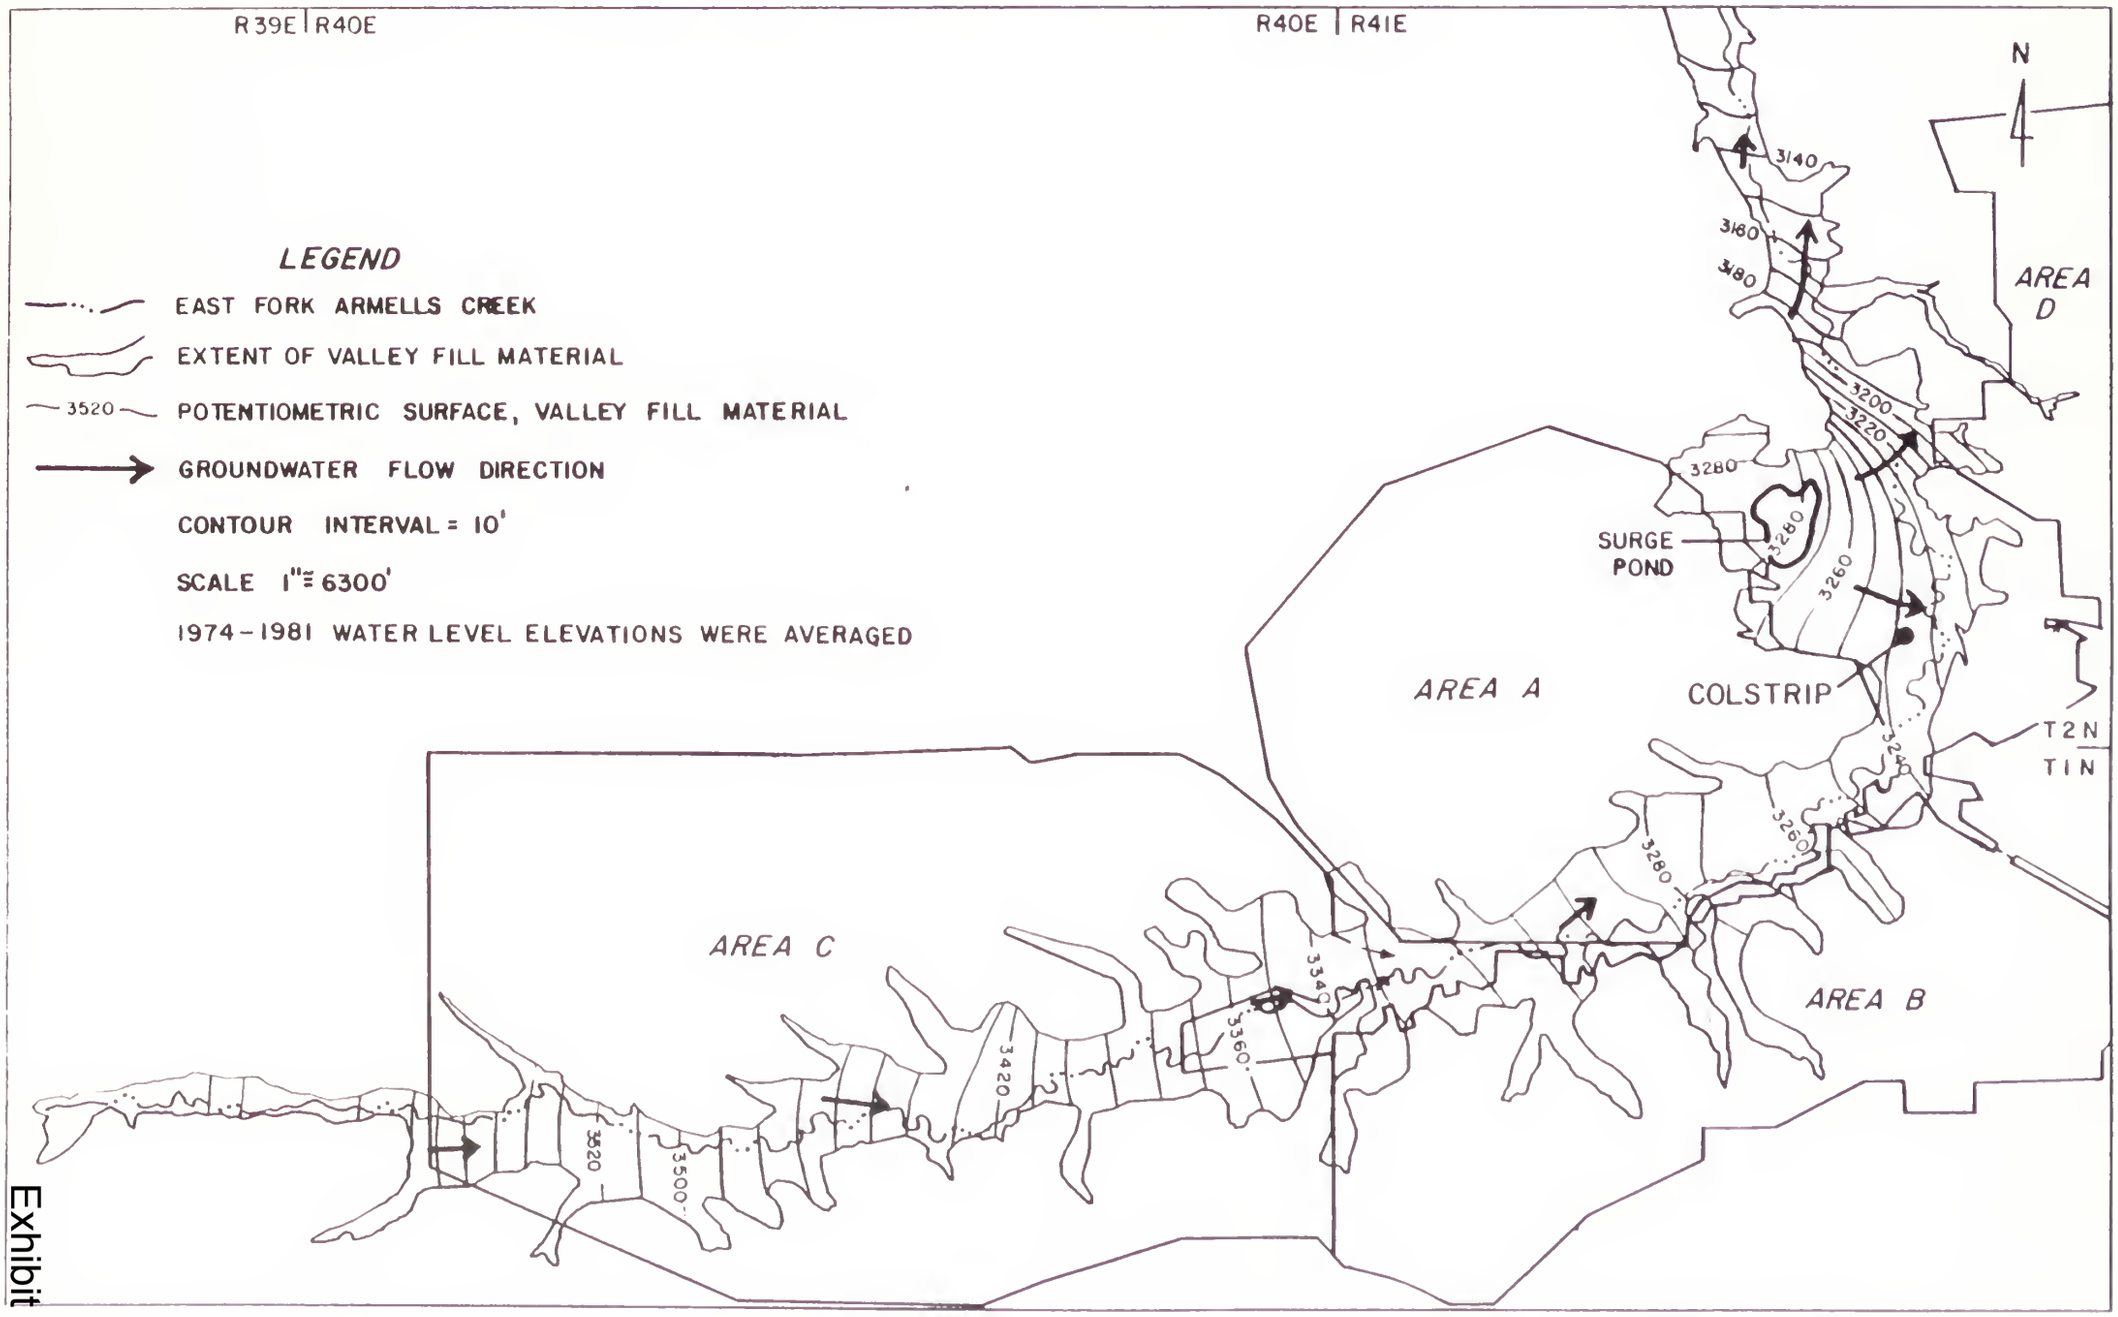

FIGURE II-7 POTENTIOMETRIC SURFACE MAP OF VALLEY FILL AQUIFER
ROSEBUD MINE, MONTANA

Exhibit 3

d) Rosebud Coal

The direction of groundwater flow within the Rosebud coal aquifer is illustrated in Figure II-8. Regional flow originates in the vicinity of Area C and moves from that groundwater high to the south, southeast and east. The hydraulic gradient in the Rosebud coal aquifer follows the structural dip of the unit.

Conditions in the Rosebud coal aquifer vary from confined to unconfined, as shown in Figure II-9, where the bedrock is apparently faulted and fractured. It is not clear whether the faulting has caused groundwater conditions to become unconfined, or if it is because the Rosebud coal seam is almost entirely exposed between the faults. The faults do not appear to cause significant changes in the regional lateral direction of flow in the Rosebud. The fact that the coal has been offset, but the flow remains unaffected, seems to indicate that vertical hydraulic communication may also be occurring across the fault zone. It is possible that the faulted area provides an excellent conduit for vertical groundwater flow.

e) Rosebud/McKay Interburden

The nature of flow in the Rosebud/ McKay interburden has not been well defined. The interburden is probably largely unconfined, with discontinuous lateral saturation. The regional direction of flow is probably structurally controlled (i.e., northwest to southeast). Water occurring in the interburden probably comes from minimal leakage downward from the Rosebud coal and upward from the McKay coal, depending on the portion of the study area examined.

f) McKay Coal

Figure II-10 is an illustration of the regional flow in the McKay coal aquifer. Flow directions are very similar to those observed for the Rosebud coal aquifer, and are, once again, similar to the structural dip of the rock unit.

g) Sub-McKay

Although a large percentage of domestic wells are completed in the sub-McKay unit there is little specific data on the groundwater flow. The aquifer is confined by a 30-foot thick layer of clay situated at the top of the sub-McKay unit. This clay layer effectively separates flows in the sub-McKay from the McKay coal aquifer. It is probable that the southeast structural dip of the sub-McKay aquifers is a controlling factor in the direction of flow, as is the case with the Rosebud and McKay coal aquifers.

2) Aquifer Communication

There are four major modes of communication between water-bearing strata:

- Vertical leakage from the McKay coal seam
- Movement along faults

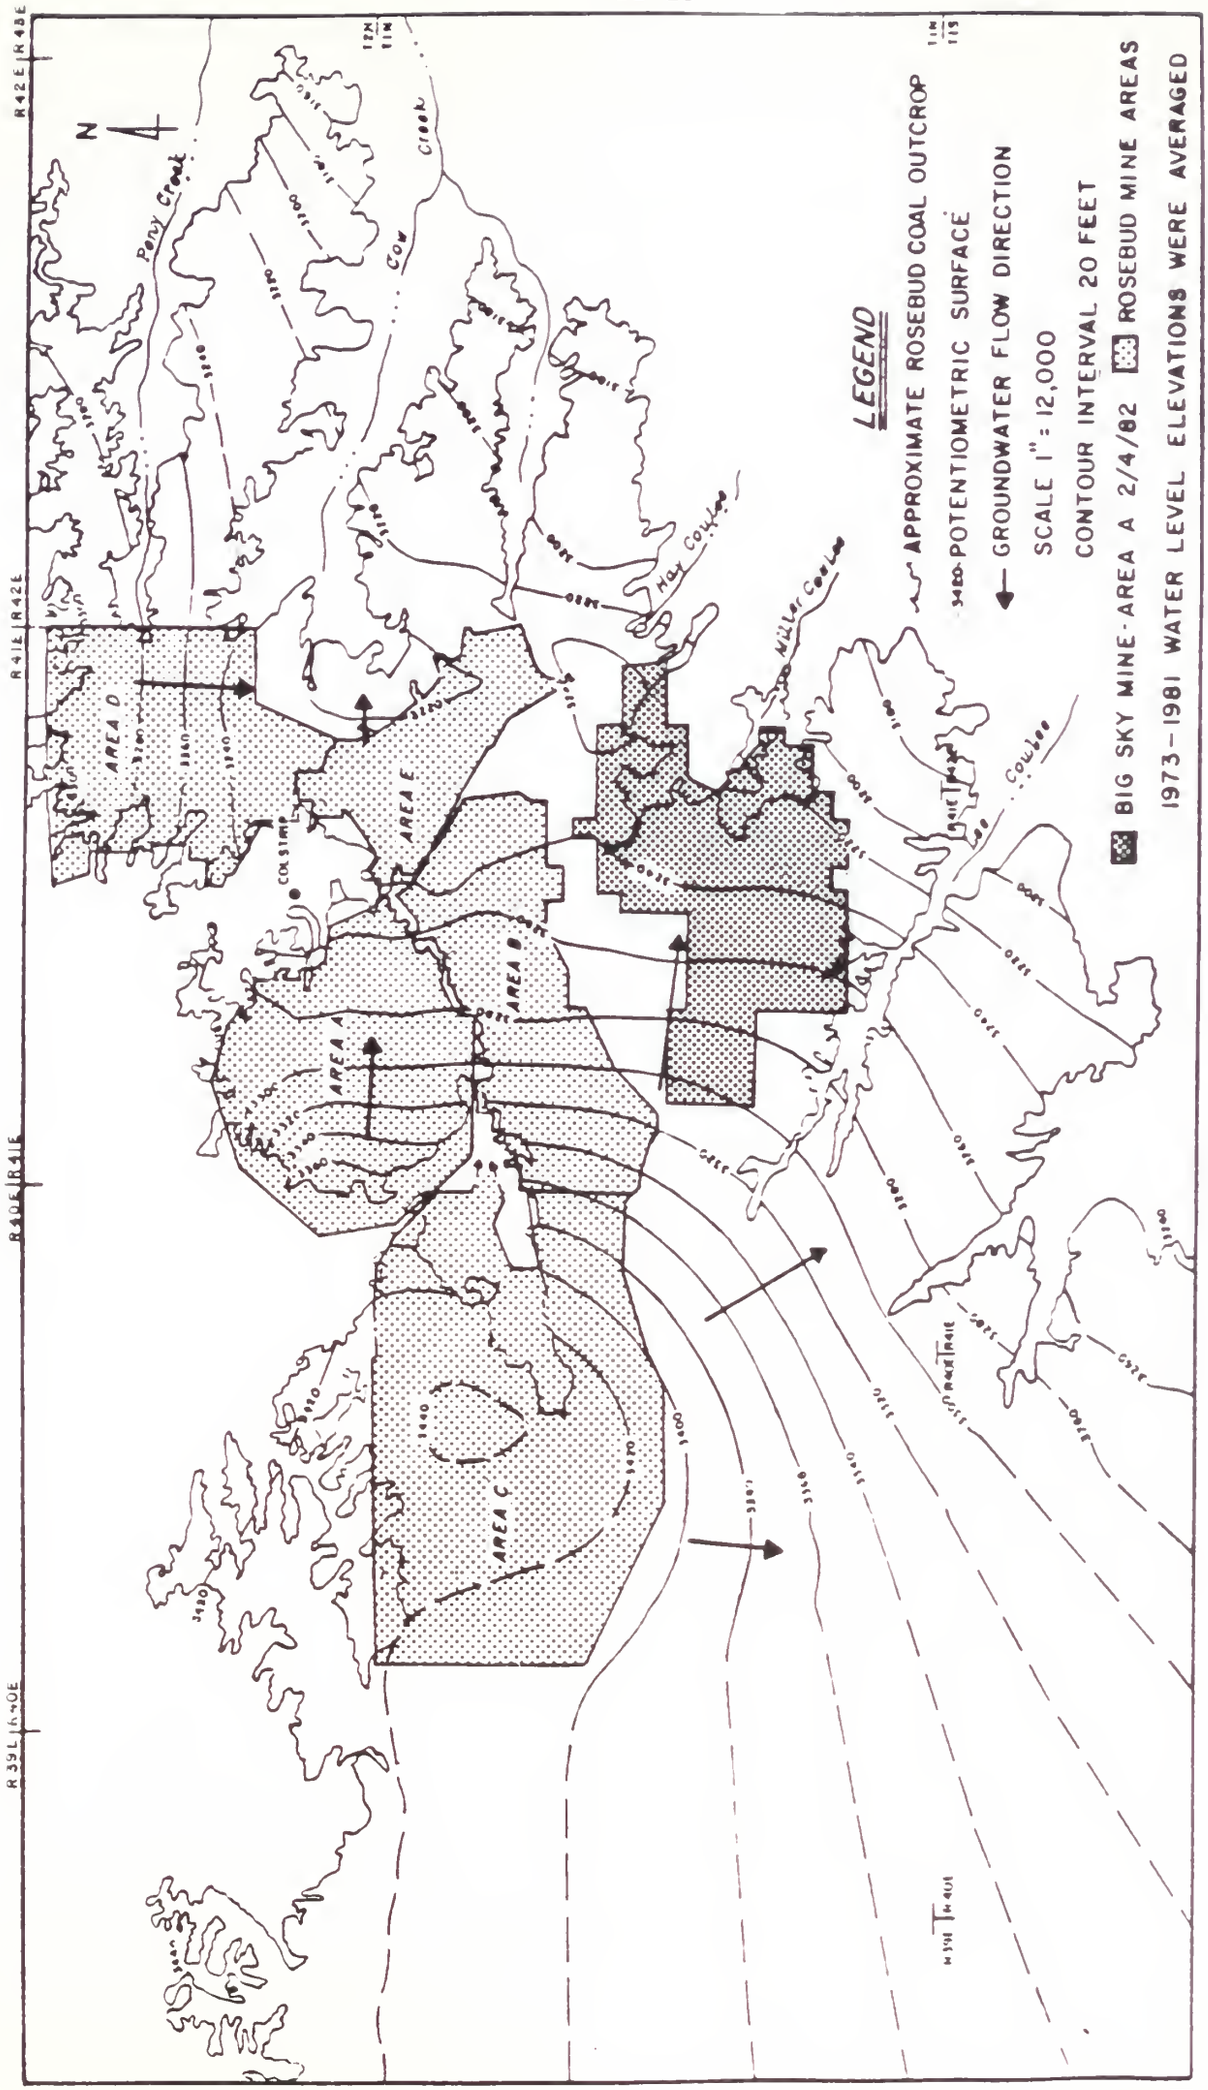

FIGURE II-8 REGIONAL POTENTIOMETRIC SURFACE OF ROSEBUD COAL AQUIFER, ROSEBUD & BIG SKY MINES, MONTANA

Exhibit 3

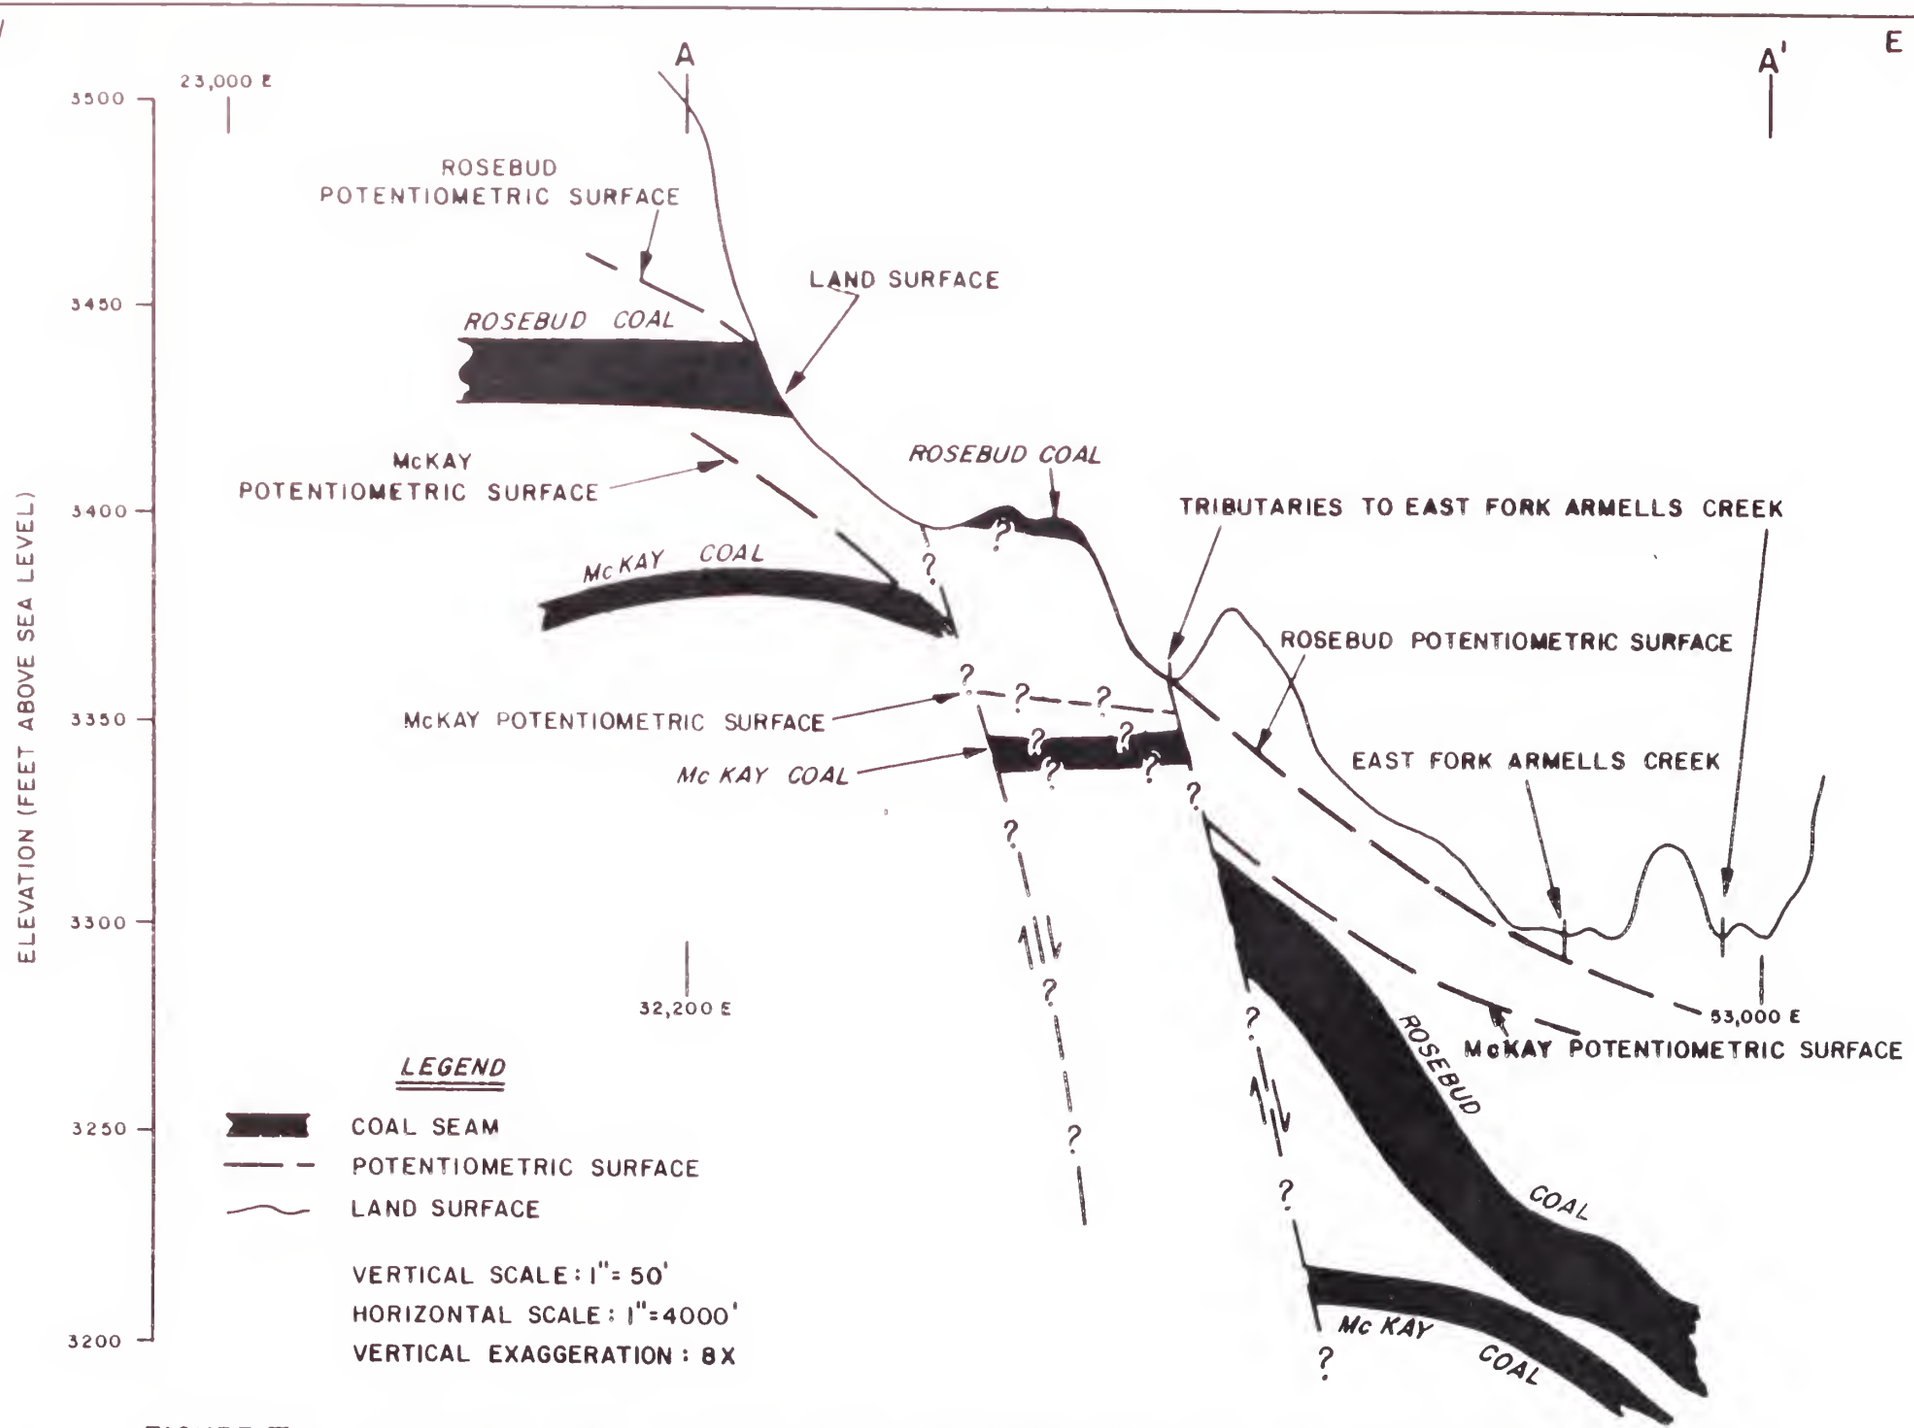

FIGURE II-9 POTENTIOMETRIC SURFACE AND STRUCTURAL CROSS SECTION ACROSS TWO FAULTS ROSEBUD MINE, MONTANA

SEE FIGURE II-13 FOR LOCATION OF CROSS SECTION

Exhibit 3

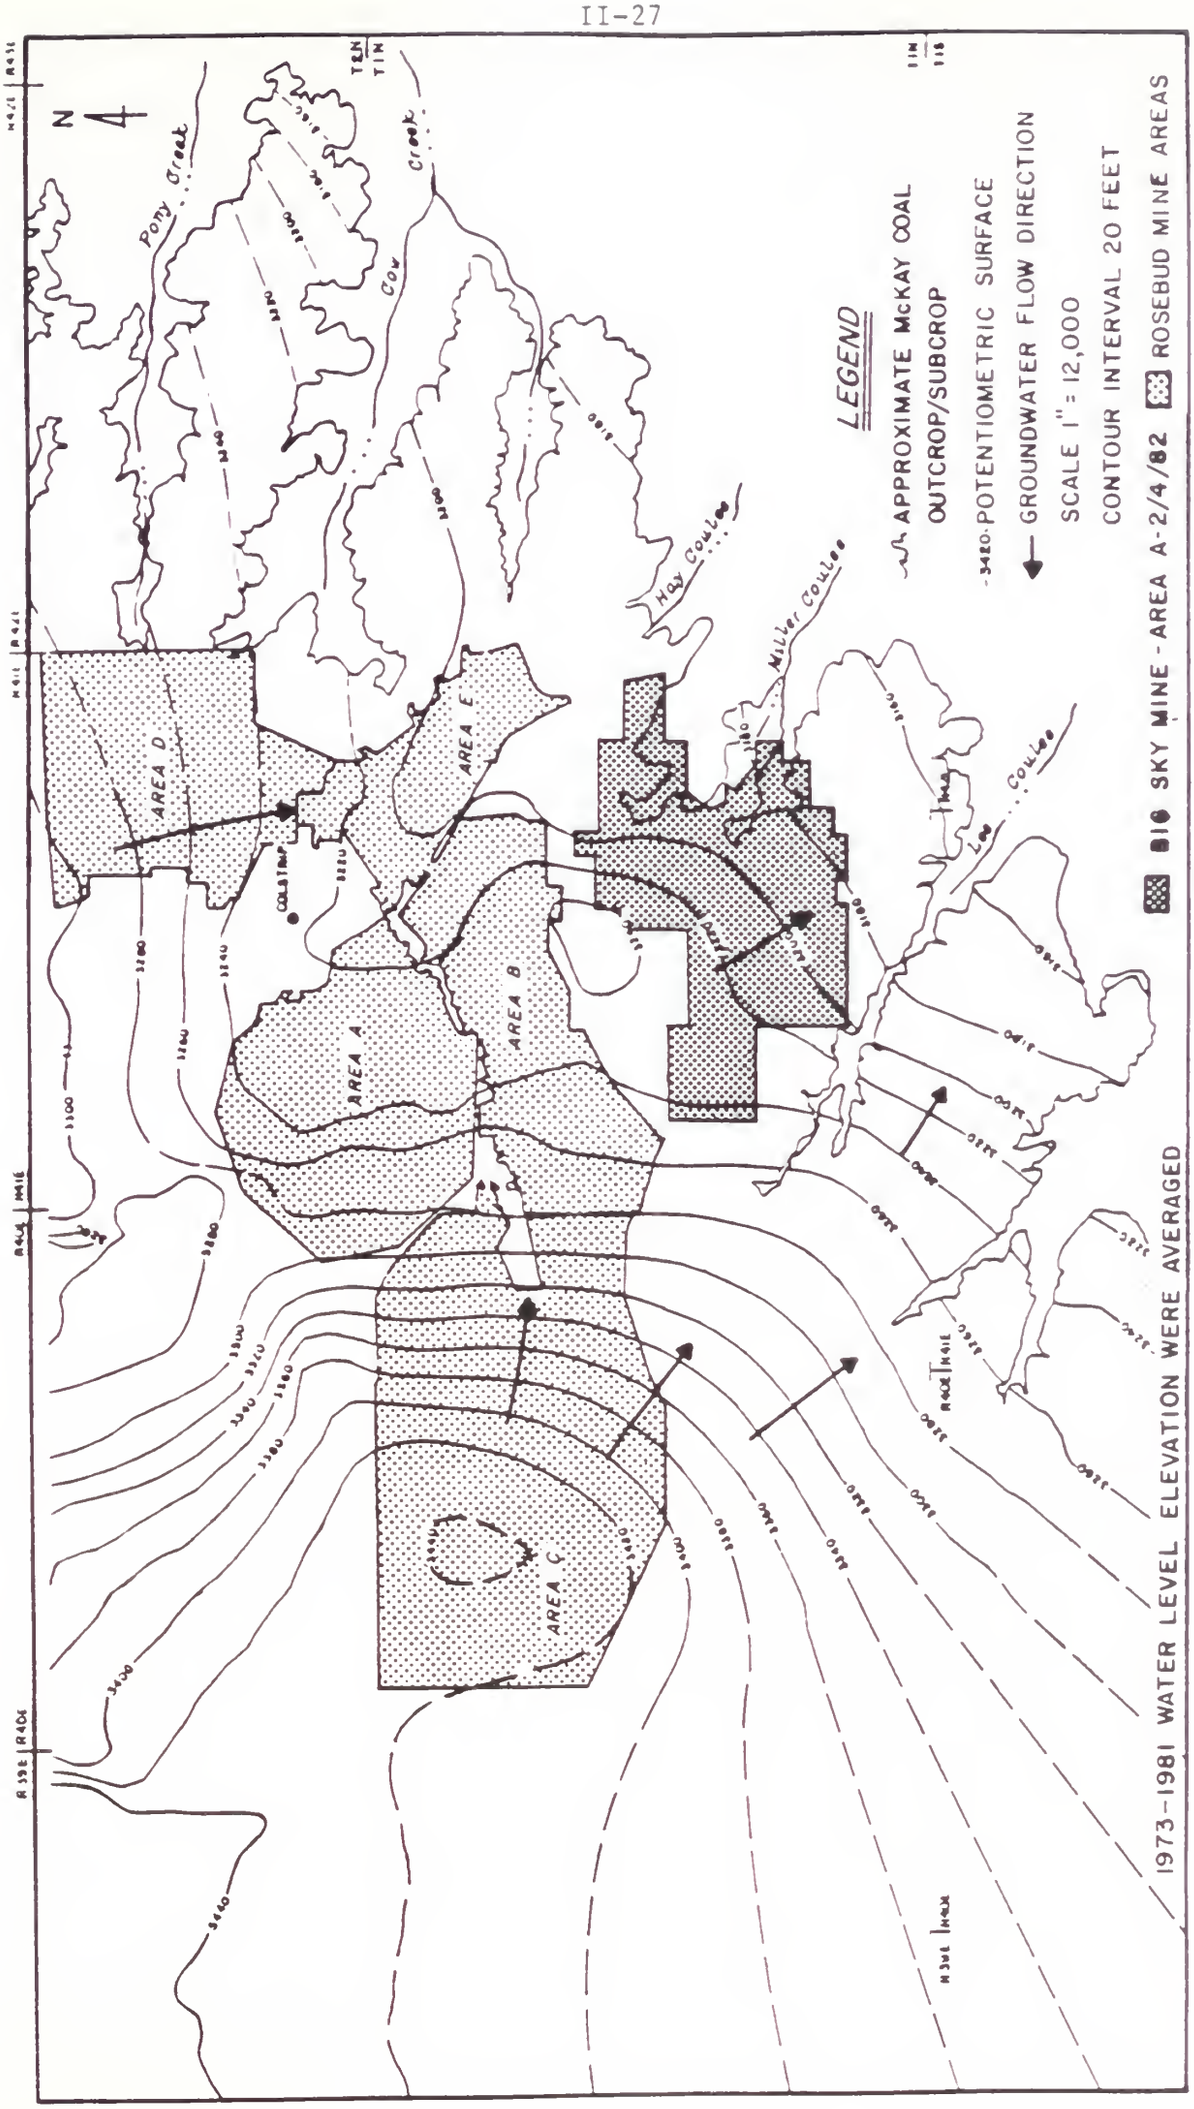

FIGURE II-10 REGIONAL POTENTIOMETRIC SURFACE OF McKAY COAL AQUIFER, ROSEBUD & BIG SKY MINES, MONTANA

Exhibit 3

- o Exchange between consolidated* and unconsolidated* materials
- o Exchange betwen two unconsolidated, water-bearing strata

Water levels in Area B wells WM-102 and WM-103 (refer to Figure II-5) completed in the McKay coal have been observed to decline. This indirectly suggests that mining of the Rosebud coal in Area B has allowed for an increase in upward vertical leakage from the McKay coal seam.

As previously mentioned, faulting occurs in both the McKay coal and the Rosebud coal west of Colstrip. The fact that the groundwater becomes unconfined in the vicinity of the faulting and that there are some anomolously high transmissivities in bedrock aquifers close to the fault suggest the possibility that the faults and related fractures allow for intermingling of water between the McKay and the Rosebud coal seams, depending on the vertical hydraulic gradient.

Clearly, wherever the spoils or valley fill material are in direct contact with bedrock strata the potential exists for either the bedrock to discharge to unconsolidated strata, which is most common, or for the spoil or valley fill to recharge the bedrock.

In some areas along East Fork Armells Creek, Rosebud coal spoils have been placed in direct contact with valley fill. There is no clear subsurface evidence to indicate that spoils are in direct contact with valley fill in any other drainages. Where the spoils in contact with East Fork Armells Creek valley fill receive significant infiltration or inflow from bedrock, groundwater may flow laterally through the spoils into the valley fill. However, this contribution to the valley fill is probably not significant, as compared with the normal flow through valley fill.

3) Groundwater Recharge-Discharge

Groundwater recharge and discharge is usually inferred from groundwater flow data. In an area where there is a high point on a potentiometric surface (or groundwater contour) map water must flow away from that area. Also, water must be contributed to the aquifer as recharge in that area in order for the groundwater high point to be maintained. However, a goundwater high cannot by itself be interpreted as a significant area of groundwater recharge since spatial and topographic configurations can cause a groundwater high even if recharge is uniform through a regional area.

Discharge may be inferred by places where groundwater contours come to the surface and the strata transmitting the water either crops out or comes close enough to surface for discharge to occur. The relationship is, of course, not always simple and many gray areas exist.

Rosebud spoils receive net infiltration (or recharge) from precipitation during the autumn to early summer period. It is probable that this net infiltration is higher in unreclaimed spoils than reclaimed spoils. This difference is probably due to the fact that reclaimed spoils are revegetated, which caused higher evapotranspiration values than in unreclaimed spoils, where natural revegetation may occur slowly.

It is also due to the hummocky* nature of unreclaimed spoils where precipitation is trapped in depressions, causing it to infiltrate rather than run off.

Figure II-11 depicts recharge and discharge areas in valley fill material along East Fork Armells Creek. For most of its course above Colstrip townsite, the valley fill is receiving discharge from underlying and adjacent bedrock and from adjacent spoils. For a short section, the valley fill becomes a losing* system as it recharges bedrock just above the townsite of Colstrip. Immediately above and below Colstrip insufficient data exist to establish a relationship; however, it is logical to assume that the valley fill continues to receive recharge from the bedrock in this area.

The MPC power plant surge pond is located along the western flank of the valley downstream from Colstrip. As shown schematically in Figure II-12 the surge pond is in direct contact with valley fill materials in a minor tributary to East Fork Armells Creek. Valley fill groundwater contours of East Fork Armells Creek show the influence of seepage from the surge pond on the valley fill. This influence is visible as a groundwater mound, causing flow to move perpendicular to the direction of the creek, rather than subparallel to it. It is probable that surge pond leakage contributes to bedrock recharge, because groundwater flow in the valley fill is recharging bedrock throughout this reach of East Fork Armells Creek.

Figure II-13 illustrates the groundwater flow patterns for the Rosebud and McKay aquifers (which are essentially similar) within the hydrologic study area. Recharge is definitely occurring within proposed mine Area C, but may also be occurring in adjacent areas as well. It is possible, due to the higher sand content in overburden, the closeness of coal beds to the surface in the northern portion of Area C, and the relatively high degree of fracturing, that a proportion of recharge occurs in Area C.

As the groundwater moves south, southeast, and east away from the bedrock recharge areas, a small percentage is discharged to the spoils or valley fill adjacent to East Fork Armells Creek. However, the major portion of the goundwater is carried by the two coal aquifers and moves southeastward to discharge points along the outcrops of both aquifers, as illustrated in Figure II-13. The figure shows that significant discharge occurs along a series of coulees that are tributary to Rosebud Creek. Although the Rosebud overburden and Rosebud/McKay interburden follow the same structural trend, they do not transmit much water, and, thus, have not been considered with respect to recharge-discharge. Modeling results quantify existing discharge rates along surface drainages throughout the study area (Table III-3).

Recharge has been quantified during the process of calibrating the computer model with respect to existing groundwater conditions. It was found that an overburden recharge rate of 2.5×10^{-5} ft/day allowed for a close approximation between equilibrium modeling results and observed groundwater levels.

Exhibit 3

Exhibit 3

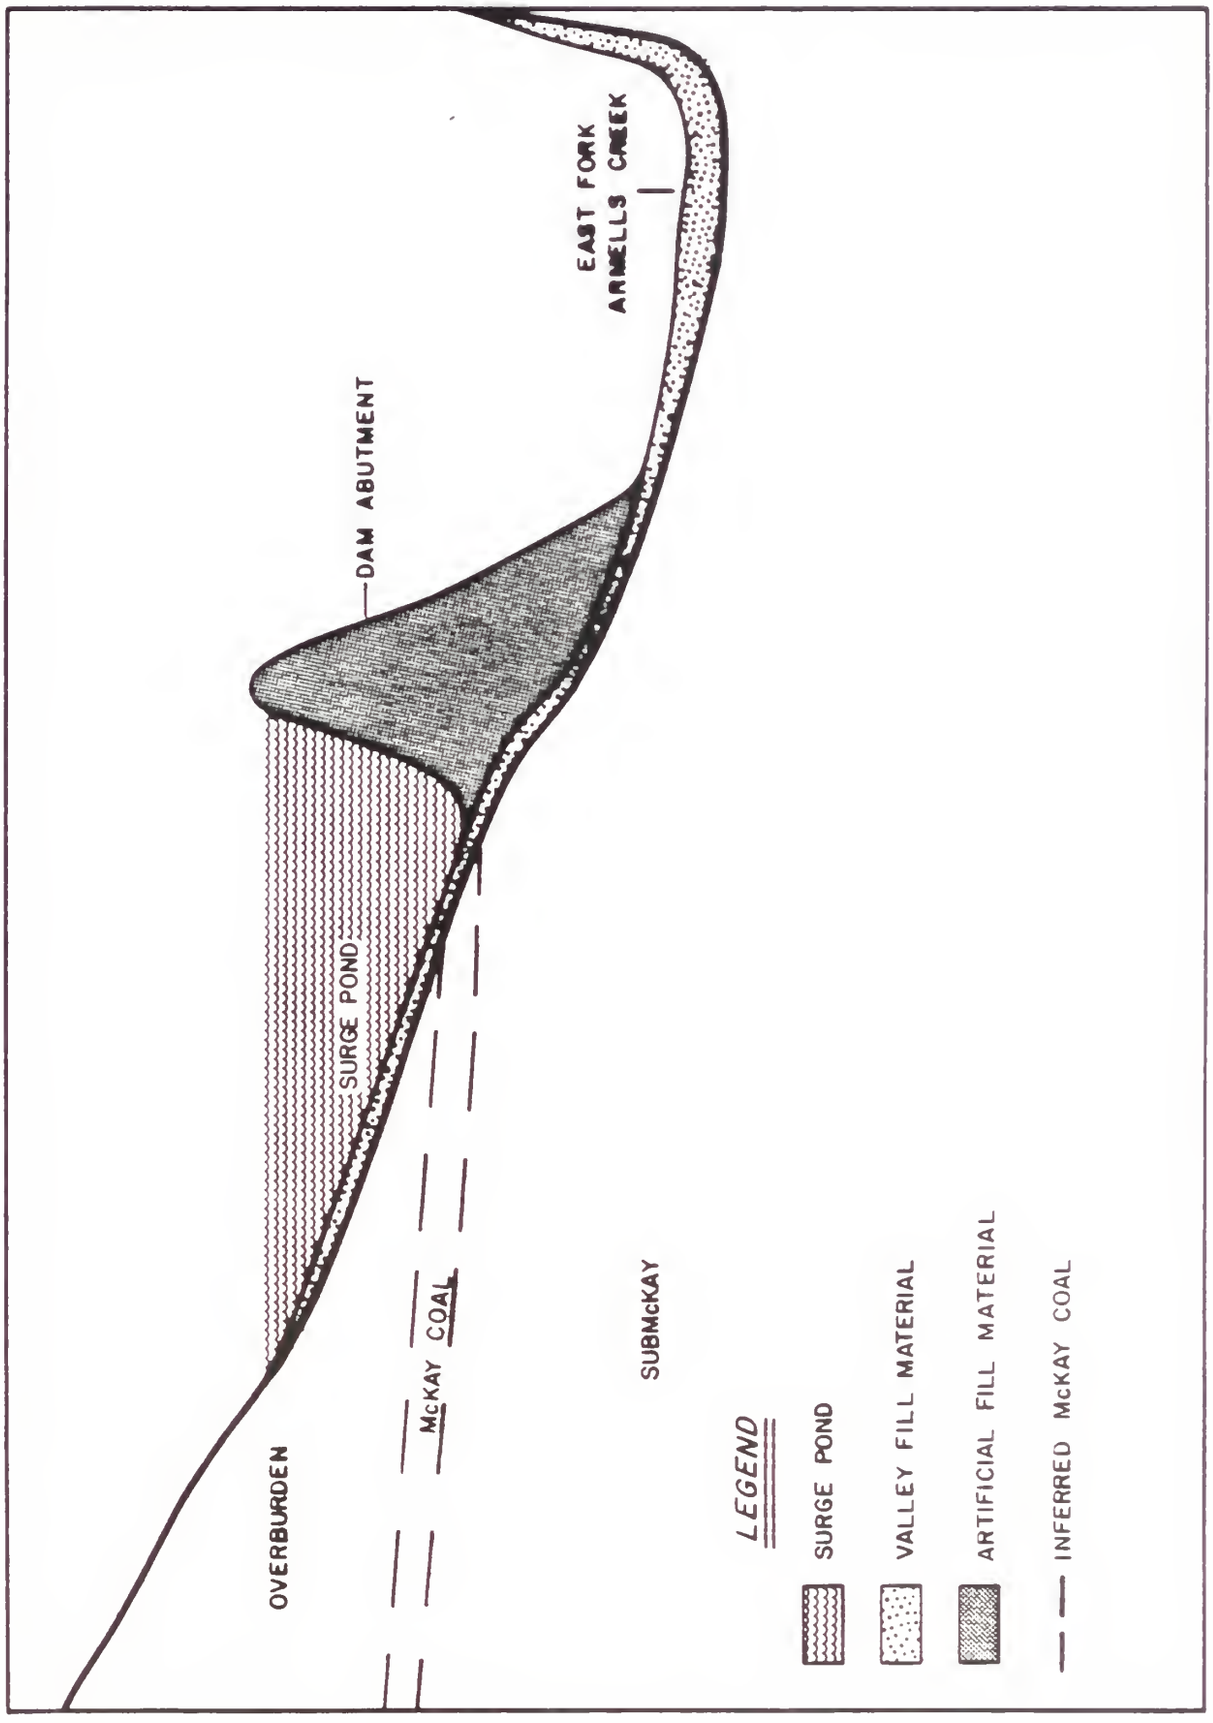

FIGURE II-12 SCHEMATIC WEST-EAST CROSS SECTION ACROSS SURGE POND, COLSTRIP, MONTANA

Exhibit 3

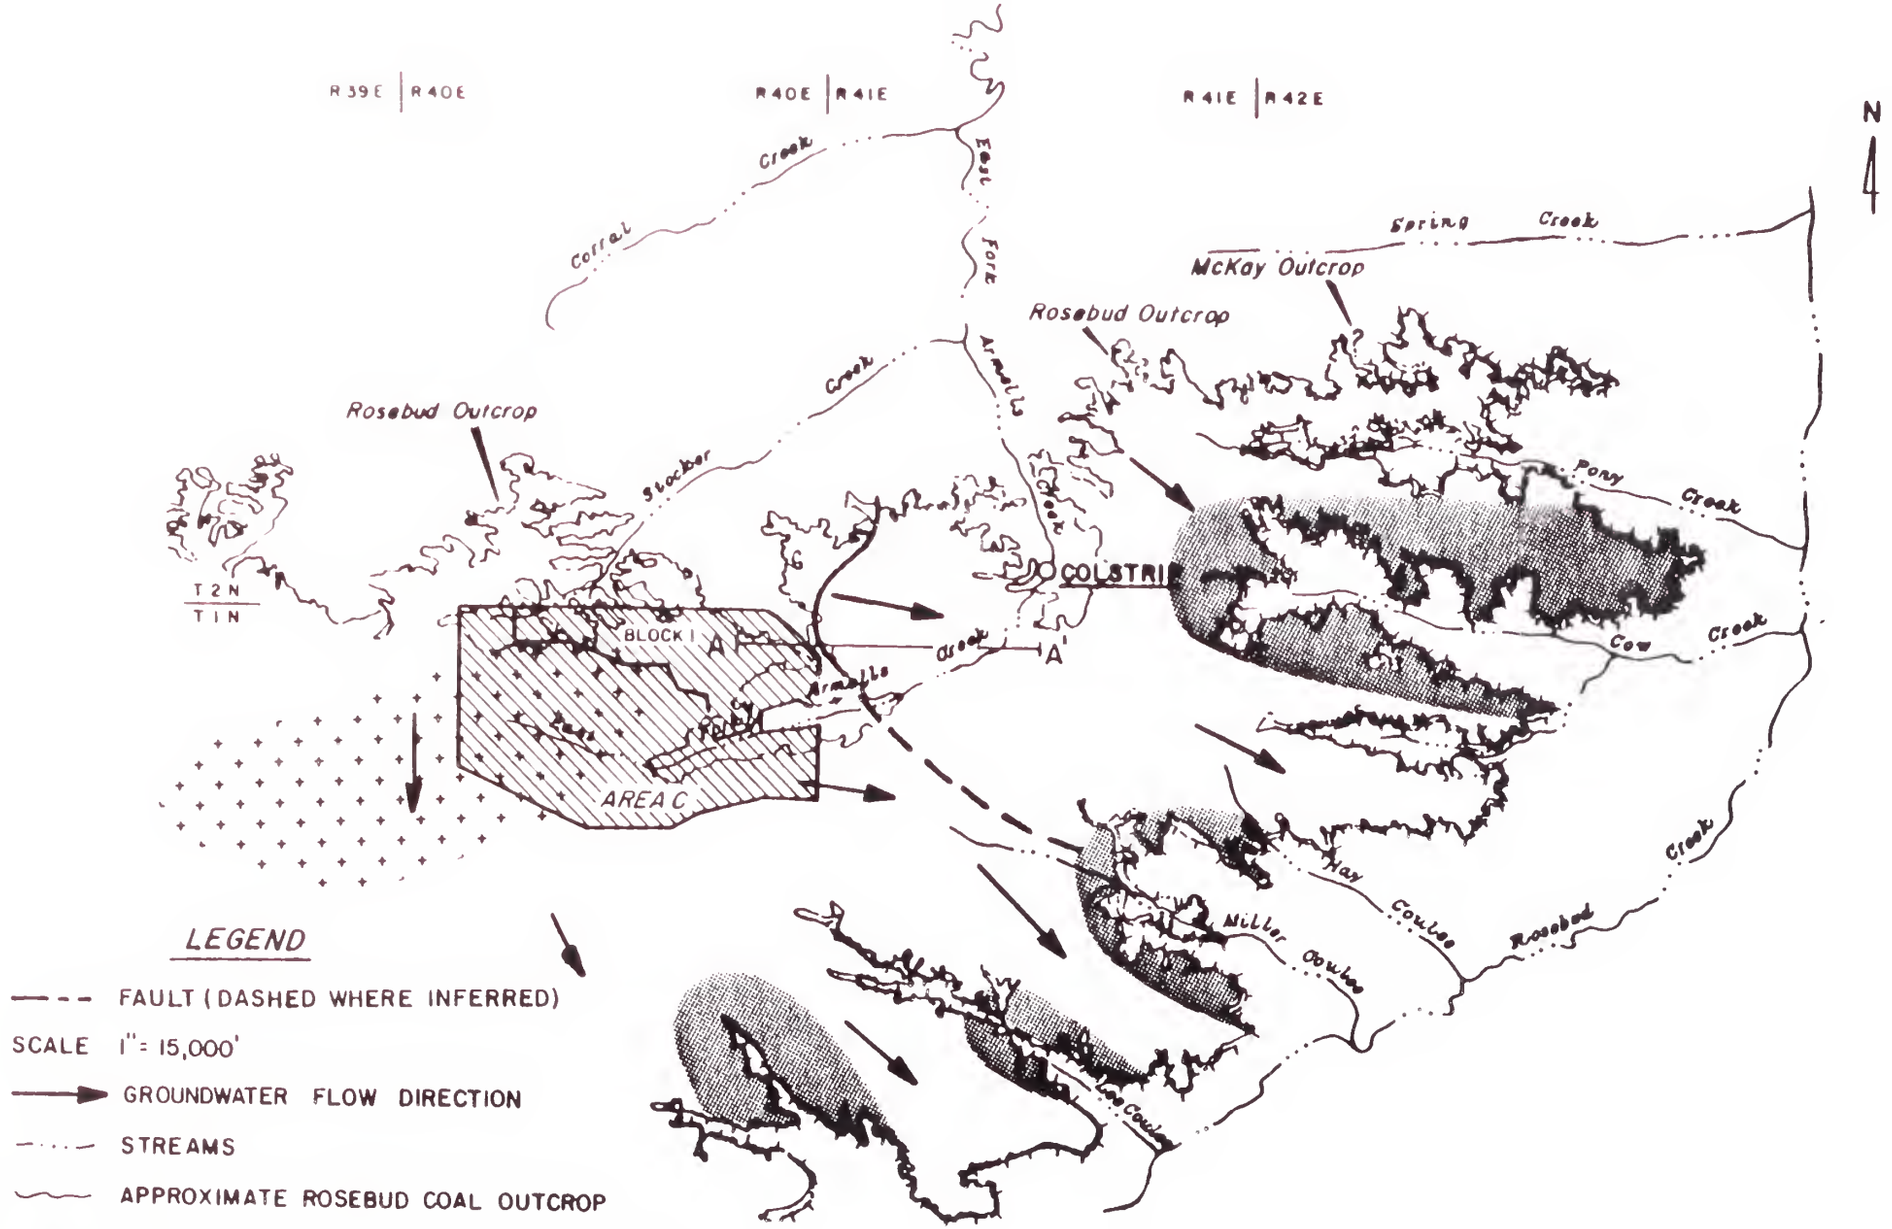

FIGURE II-13 ROSEBUD COAL AND McKAY COAL RECHARGE/DISCHARGE AREAS, ROSEBUD MINE, MONTANA

Exhibit 3

There is a relationship between the surface hydrologic structures such as the surge pond, the fly ash and evaporation ponds, the power plant ponds, the sewage lagoon, and the recharge-discharge of area groundwater. The majority of the ponds are known to leak and the amount of this leakage has been established for most of the ponds. Table II-4 presents information concerning the location and construction of these structures and the estimated amounts of seepage from each.

The seepage from these structures is a source of recharge to the valley fill system and also probable recharge sources to the bedrock system.

The effects of this recharge are two-fold. The most apparent effect is in increased water levels in the valley fill system. This, along with the potential increased stream flow from groundwater discharge, present irrigation practices, and the current trend of increased yearly precipitation, may result in the increased severity of the water logging problems presently taking place downstream of Colstrip. Recent studies have concluded that while the water logging problem is a result of the increase in water in the valley fill system, seepage from surface water impoundments may not be the sole reason for this occurrence (Hydrometrics, 1981, 1982). Estimated seepage from surface impoundments may constitute approximately 30% of through flow of East Fork Armells Creek alluvium (see Table II-4, Estimated Pond Seepage Amounts).

The amount of net infiltration to the valley fill depends upon the season. During the summer, the valley fill groundwater is being diminished by baseflow and plant uptake, while during autumn, winter and early spring there is net positive infiltration to the valley fill.

4) Groundwater-Surface Water Relationship

The relationship between surface water and groundwater in the hydrologic study area has been addressed, to a great extent, in the discussion of recharge and discharge of groundwater. Within the hydrologic study area, groundwater from the bedrock aquifers is generally discharging to valley fill and hence to surface water along minor reaches of East Fork Armells Creek above Colstrip. For a segment of East Fork Armells Creek above (and probably below) Colstrip, the stream and the valley fill is recharging the bedrock aquifer.

Farther to the southeast, a major groundwater discharge zone occurs along a series of coulees tributary to Rosebud Creek (refer to Figure II-13). The Rosebud and McKay coal seams both outcrop along these coulees, and consequently both aquifers must discharge along these outcrops, contributing to valley fill groundwater flow in each tributary.

There is also an anomalous situation that contributes to stream flow downstream from the Colstrip townsite. Leakage from the surge pond to valley fill aquifers and then to East Fork Armells Creek occurs below Colstrip.

A Combined aggregate seepage estimate for all ponds - 21 acre-feet/year

Exhibit 3

During periods of high streamflow, there is the potential for surface water to recharge valley fill where water may be stored temporarily in valley fill materials. This water would either drain back into the channel or remain as part of the valley fill groundwater, depending upon the groundwater level.

The extent of subirrigation in the valley fill material depends on depth to groundwater, texture of the valley fill material, the type of vegetation, and relationships between ground and surface water. Subirrigation occurs where a combination of groundwater depth and capillary fringe brings water to within 14.5 feet of the ground surface where agricultural plants such as alfalfa can use it. The 14.5-foot depth is considered the maximum depth at which alfalfa can efficiently obtain water for plant maintenance and growth (Dollhopf, 1981). Along East Fork Armells Creek, a capillary fringe of 2.5 feet was estimated, based on averaged textural analyses and discussions with Dr. Doug Dollhopf of Montana State Univeristy. Thus, a depth to groundwater of 17 feet is considered the maximum for subirrigation to occur along East Fork Armells Creek. Figure II-14 illustrates the areas in which, according to the above criteria, subirrigation is known or expected to occur.

5) Summary of Relationships Between Area C, Block I and the Hydrologic Study Area

Throughout the section on groundwater flow, groundwater movement within the hydrologic study area has been discussed. It is of particular interest to focus on Area C of the hydrologic study area to delineate aspects of groundwater flow that are considered to be unique with respect to flow in the larger hydrologic study area.

The groundwater flow system in Area C, Block I is simpler than the larger area. The major characteristics of flow in this area are: 1) Area C serves as a recharge area for the Rosebud and McKay coal seams; 2) groundwater flow is in a south, southeast and easterly direction; and 3) some of the groundwater is discharged to the valley fill along East Fork Armells Creek. Exactly which bedrock unit is contributing flow to valley fill depends upon the reach of the stream (refer to Figure II-11). The course of East Fork Armells Creek through Area C is nearly on strike (normal to the dip of beds), so that as the stream valley floor drops in elevation it contacts deeper strata.

As an area of groundwater recharge, Area C ultimately contributes to flow in tributaries to Rosebud Creek.

c. Groundwater Quality

Groundwater quality in the Rosebud Mine area is influenced and controlled by geology, climate, and human activities. Geologic materials controlling near-surface water quality are Rosebud spoils, valley fill material, Rosebud coal overburden, Rosebud coal, Rosebud/McKay interburden, and McKay coal. The physical and hydraulic characteristics of

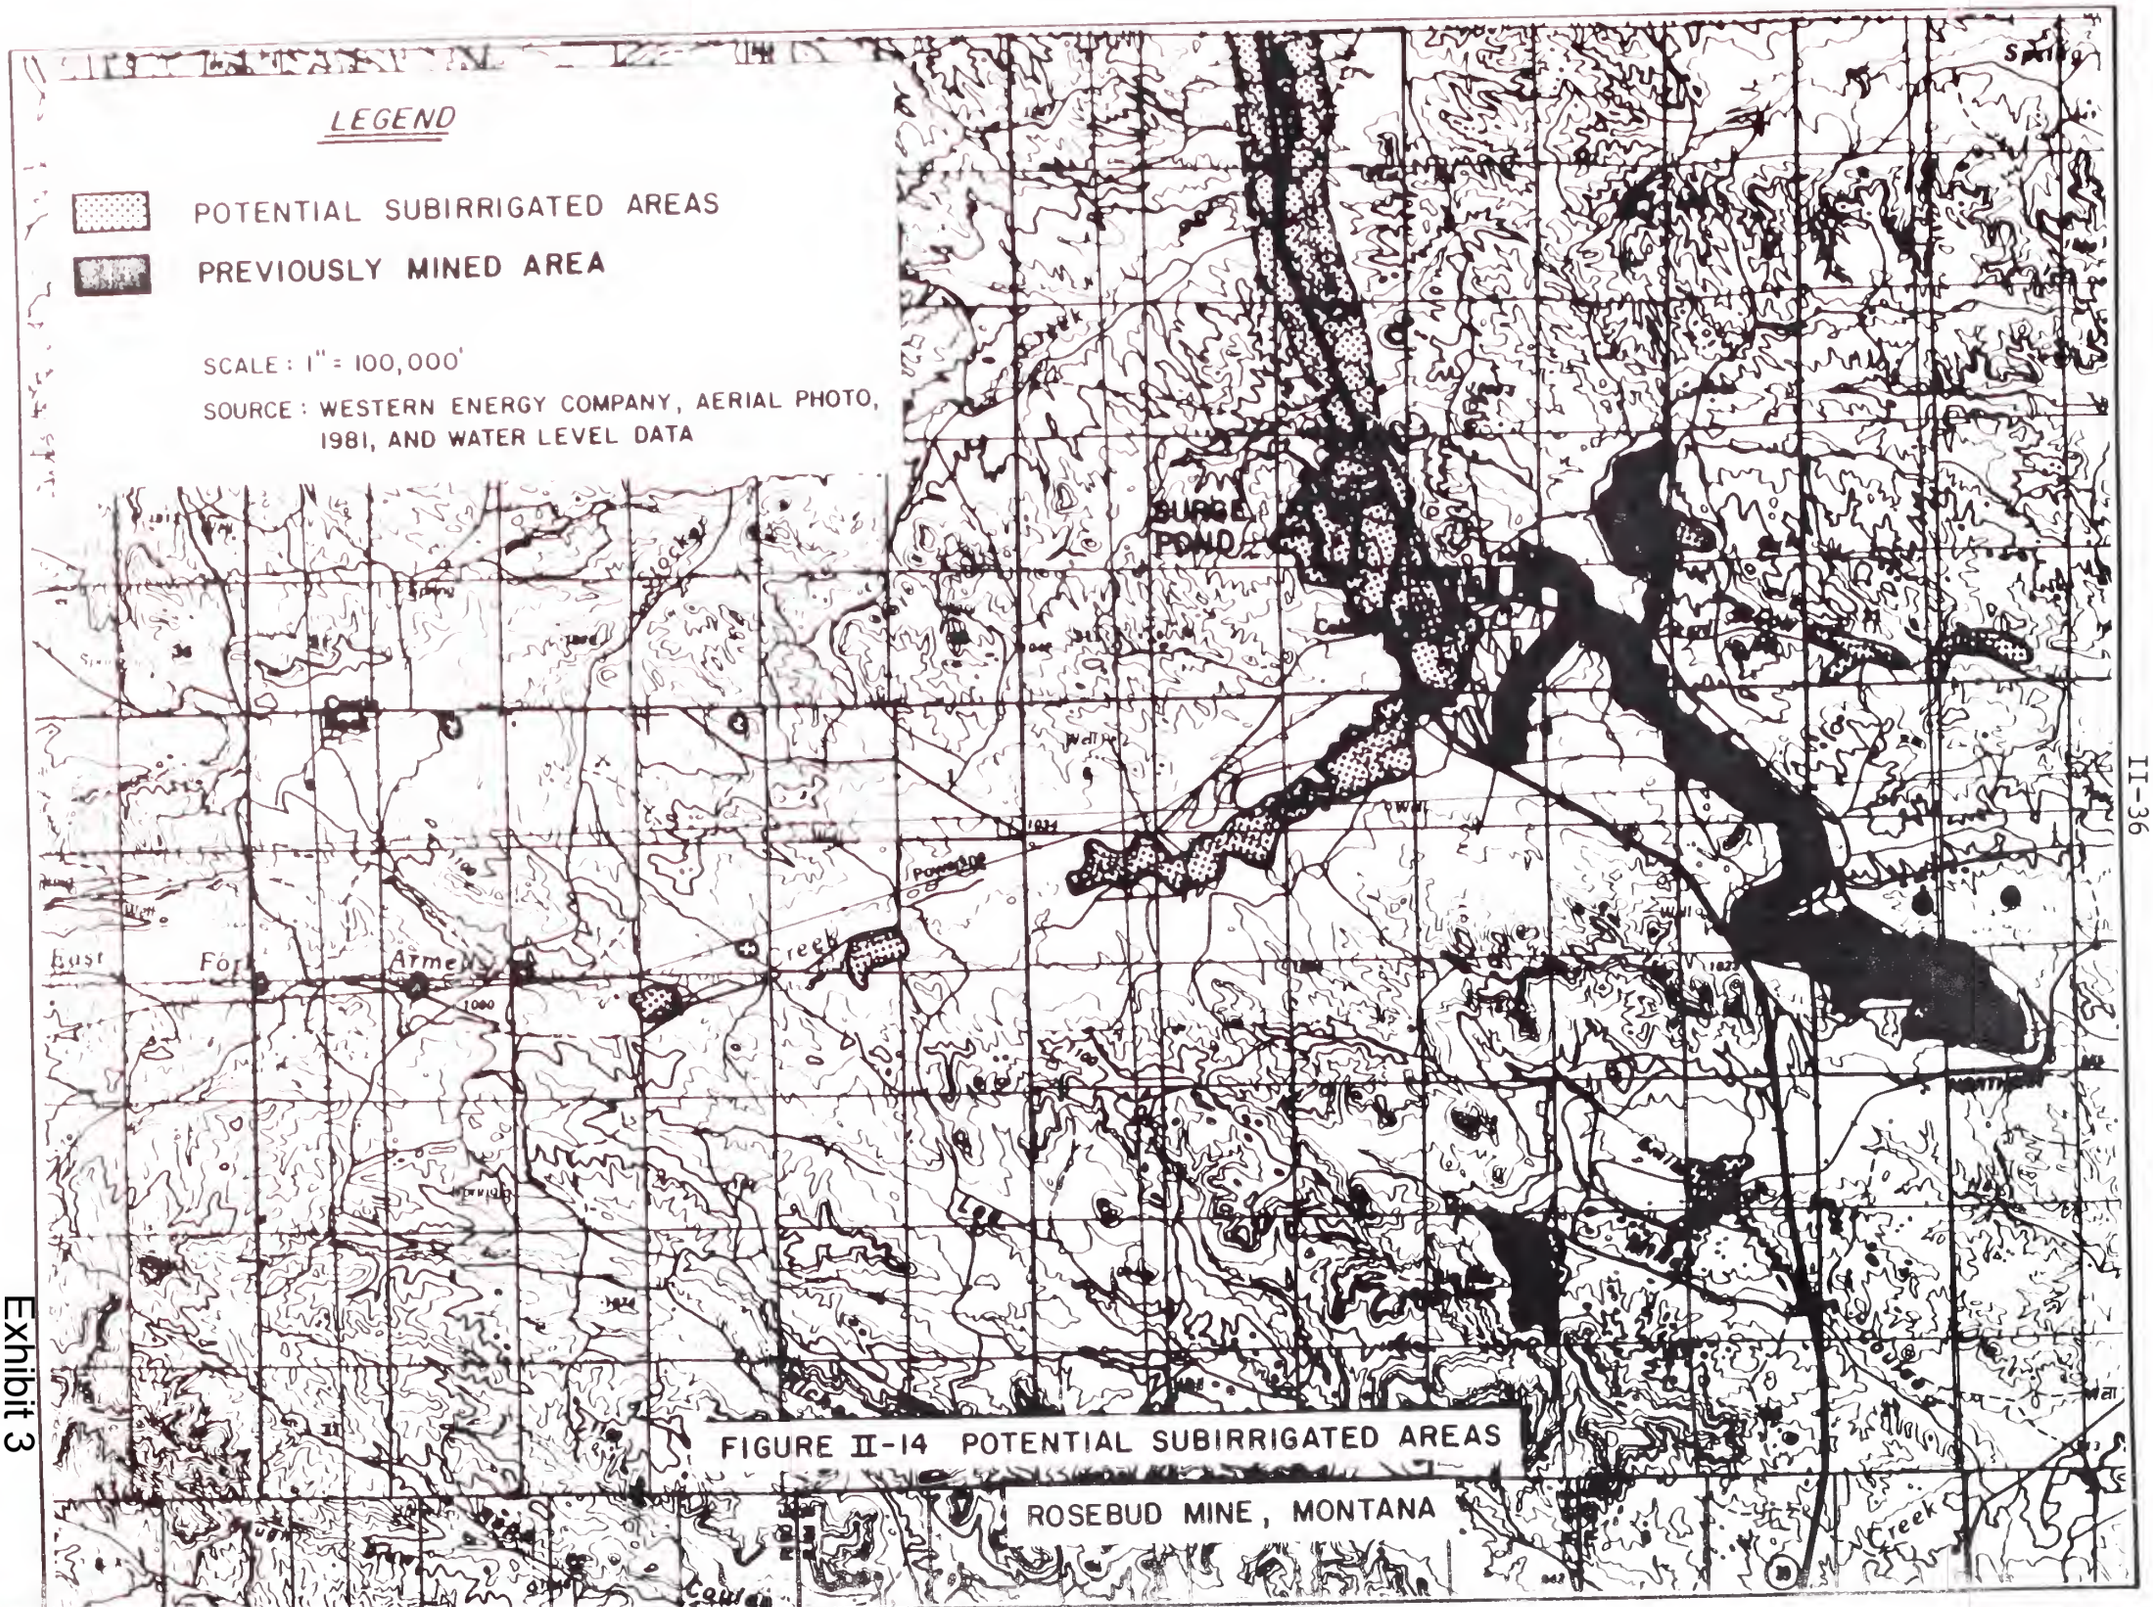

FIGURE II-14 POTENTIAL SUBIRRIGATED AREAS

ROSEBUD MINE, MONTANA

Exhibit 3

each of these water-bearing strata were discussed earlier in Section B.1.a of this chapter.

The influence of climate on water quality in the Rosebud Mine area is generally related to the number, duration, and frequency of precipitation events. Climatic factors are discussed in Section C of Chapter II.

Human activities influencing groundwater quality in the Rosebud Mine area are mining, the MPC electric generating facility, and community activities at Colstrip townsite. The areal extent to which groundwater in the vicinity of the Rosebud Mine has been potentially affected by human activities is depicted in Figure II-15.

The present-day quality of groundwater in Area C has not been affected by human activity.

In the following sections, the existing quality of water in each water-bearing unit is discussed, preceded by a discussion of water quality suitability criteria.

1) Water Quality Suitability

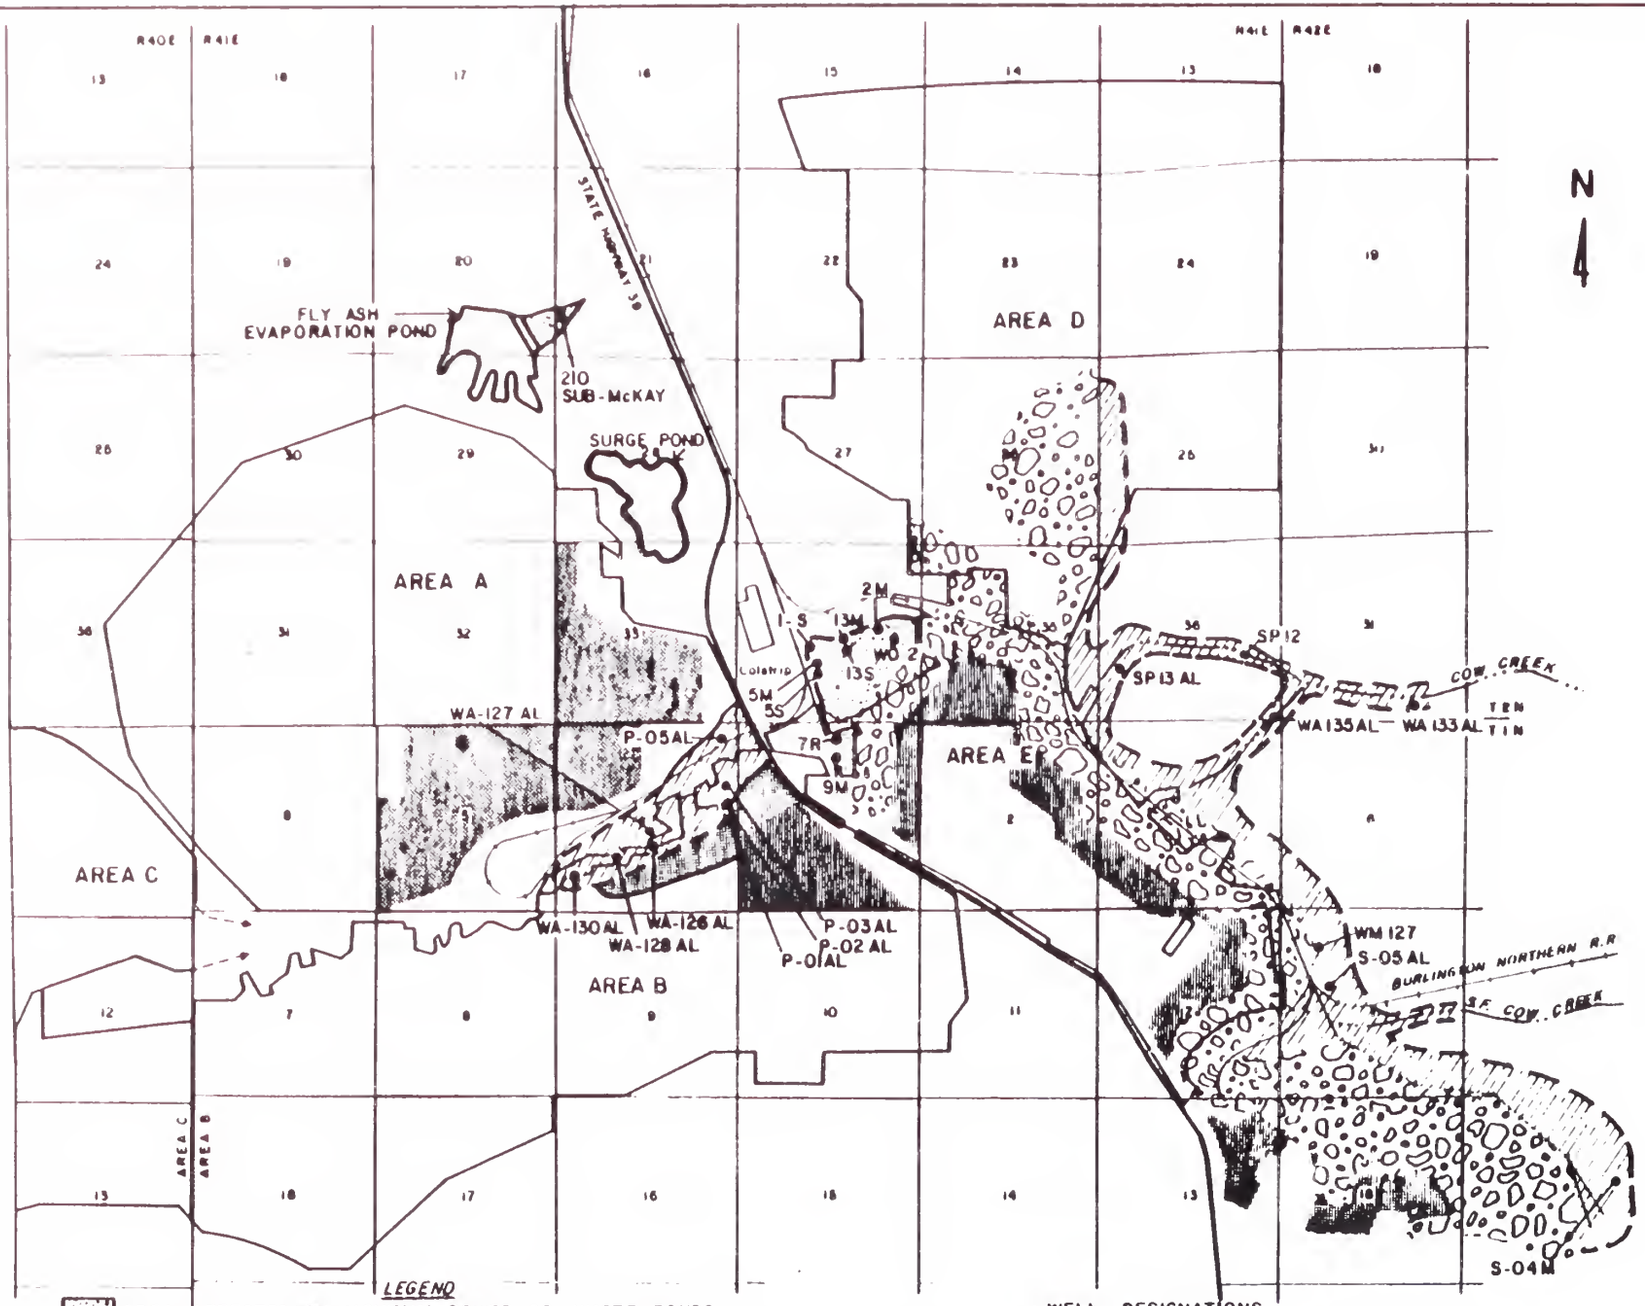
Suitability of waters for irrigation depends to a large extent on factors such as soil type, drainage conditions, management practices, crop type, and on the salinity* hazard* of the water. The classification shown in the following table, as modified from the U.S. Salinity Laboratory Staff (1954), is often used with respect to irrigation water:

Salinity hazard	Range of dissolved solids
Low	Less than 170 mg/l
Medium	170-500 mg/l
High	500-1,500 mg/l
Very High	More than 1,500 mg/l

Raising livestock is an important industry throughout the Rosebud Mine area and stock watering is an important water use. Livestock tolerance to high levels of dissolved solids depends upon the type and age of stock and the period of adjustment to higher levels. Stock water standards for Montana waters (McKee and Wolf, 1971) are shown below:

Category	Range of dissolved solids
Good	Less than 2,500 mg/l
Fair	2,500-3,500 mg/l
Poor	3,500-4,500 mg/l
Unfit	More than 4,500 mg/l

Poultry, pigs, horses, cattle, and sheep (in respective order) have increasing degrees of tolerance to salinity. McKee and Wolf (1971) list the suggested upper limits of dissolved solids concentration for various types of stock as follows:



NOTE: EFFECT OF SPOILS BOUNDARY DASHED WHERE INFERRED
WELLS SHOWN HAVE RECORDS WHERE EFFECTS ARE EVIDENT OR SUSPECT
OTHER WELL LOCATIONS SHOWN ON FIGURE II-5

FIGURE II-15 WATER QUALITY MAP SHOWING AREAS AFFECTED AND POTENTIALLY AFFECTED BY HUMAN ACTIVITIES, ROSEBUD MINE AREA

Exhibit 3

Livestock	Concentration, in milligrams per liter
Poultry	2,860
Pigs	4,290
Horses	6,430
Cattle (dairy)	7,150
Cattle (beef)	10,100
Sheep (adult)	12,900

Some investigators suggest that these values are much too high for optimal growth and development of livestock. It has also been determined that certain major ions may be more limiting than the sum of all constituents. For example, stock can tolerate higher dissolved solids when the water is a sodium-chloride type (McKee and Wolf, 1971).

Most groundwaters in the Rosebud Mine area and Area C have average TDS concentrations ranging from 1,500 to 2,500 mg/l. The range of concentrations normally varies from 500 to 3,500 mg/l. For livestock use, this range would fit the categories of "fair" to "good," however, as applied to irrigation, the salinity hazard classification indicates that a "very high" hazard exists. The fact that an agricultural economy has been viable in the Rosebud Mine area for many decades demonstrates the adequacy of water quality in this part of Montana.

2) Quality of Water-Bearing Strata

A summary of water quality constituent concentrations for the Rosebud spoils and the other water-bearing strata in the Rosebud Mine area and for Area C is provided in Table 1 of Appendix B, and is detailed in the following sections.

a) Rosebud Spoils

The groundwater that occurs in the spoils generally has higher TDS concentrations than the Rosebud overburden or the Rosebud coal aquifers. Average TDS level in the Rosebud Mine area for 35 spoils wells is 3,300 mg/l, as compared to 1,250 mg/l for 22 wells in the Rosebud overburden aquifer and 1,890 mg/l for 55 wells in the Rosebud aquifer. TDS levels of spoils wells at the Big Sky Mine average 3,400 mg/l.

An increase in calcium, magnesium, sodium, bicarbonate, sulfate, and chloride was recorded for spoils wells, which is generally in proportion to the increases in TDS found in Rosebud overburden and Rosebud coal wells. Concentrations and ranges of individual constituents are presented in Table 1 of Appendix B. The pH* of spoils waters is slightly lower than that of overburden waters, ranging from about 6.8 to 7.8; whereas, the pH for overburden water ranges from 7.2 to 8.4. Iron concentrations are slightly lower; whereas, manganese is slightly higher in spoils waters than in overburden waters. Other trace elements are comparable in overburden and spoils. Spoils waters fall into a fair-to-poor category for livestock watering.

Exhibit 3

b) Valley Fill Aquifer

Water quality in the valley fill of the Rosebud Mine area is quite variable, with TDS ranging from about 1,300 to 6,000 mg/l. The average concentration for all wells is about 2,800 mg/l. Highest concentrations, in the range of 3,500 to 6,000 mg/l, are found at random locations and result from natural causes and the impact of mining. An effect of mining operations on valley fill water quality in the headwaters of Cow Creek and on East Fork Armells Creek is suspected. However, some of these elevations may result from natural causes. Because there has been no detailed water quality investigation prepared for Cow Creek prior to milling disturbance (pre-1950 mining) a comparison between pre-mining and post-mining TDS levels cannot be made . Wells showing evidence of water quality changes are as follows:

Well Number[1]	Maximum TDS Concentration (mg/l)	Area-Location
S-05	6,000	Cow Creek
S-13	4,530	Cow Creek
WA 133	3,930	Cow Creek
WA 135	4,340	Cow Creek
PO-5	5,110	A,B, E. Frk. Armells Crk.

[1] Refer to Figure II-5 for well locations

Table 2 of Appendix B shows data documenting changes in TDS concentrations with time for wells P-01, P-02, P-03, and P-05. Table 3 of Appendix B compares TDS concentrations of some alluvial wells showing elevated TDS values with alluvial wells in other drainages indicating unaffected TDS levels.

Water quality in the Armells Creek Valley Fill adjacent to Area C has not been impacted by mining and is more variable than that of other undisturbed areas. TDS concentrations range from 1,390 mg/l in well WA-103 (Figure II-5) to 4,680 mg/l in well WA-121 (Figure II-5). Higher concentrations are found toward the western end of the area and in Stocker Creek headwaters, where concentrations are predominantly in the range of 2,000 to 4,000 mg/l. In the eastern portion of Area C and in the mid-reach of Stocker Creek, concentrations range from about 1,500 to 2,000 mg/l. The water is a magnesium sulfate type with hardness*, ranging from 837 to 2,430 mg/l.

Trace element and nutrient levels are at or near detection levels, which are well below drinking water standards, and should present no problems. All waters should be suitable for stock watering, the primary use in this area.

c) Rosebud Coal Overburden

Analyses of water from three wells, WO-101, WO-103, and S-23 (located on Figure II-5) drilled in the overburden in Area C show that TDS

levels range from 400 to 2,500 mg/l. The overburden well nearest to Area C, Block I is located at the western extremity of Block I and has a TDS level of 2,410 mg/l. The amont of chemical information collected from overburden wells in Area C is not sufficient for statistical comparison; however, the data are similar to data collected in Area B, which are sufficient for statistical analysis. TDS concentrations in Area B range from 600 to 2,500 mg/l, and average 1,850 mg/l. These concentrations have been used as reasonable estimates of water quality in the overburden in Area C.

d) Rosebud Coal

Some of the best quality groundwater in the Rosebud Mine area is found in the Rosebud coal aquifer (Table 1, Appendix B). TDS concentrations range from 400 to 6,500 mg/l; however, the majority of water samples had TDS concentrations in the range of 400 to 1,500 mg/l. Only three wells have concentrations greater than 3,000 mg/l in the Rosebud Mine area, two of which are located in the headwater area of East Fork Armells Creek and Stocker Creek in Area C (wells WR-103 and WR-121 on Figure II-5). The high concentrations in the western portion of Area C may be due to a higher clay and shale content in the overburden and to numerous faults, which have produced solution zones allowing deeper-seated, more mineralized waters to migrate upward into the Rosebud coal aquifer.

The three wells drilled in Area C, Block I have the following TDS concentrations: WR-122 - 534 mg/l; WR-117 - 459 mg/l; and WR-126 - 2,260 mg/l (Figure II-5). Well WR-126 is located along the outcrop of the Rosebud coal, where mineralization from the overlying shale and surface weathering are considered responsible for the higher concentration. Much of the water underlying Block I is probably similar in quality to that of wells WR-117, WR-122, and WR-126.

e) Interburden Aquifer

The predominant range of TDS for all interburden wells in the Rosebud Mine area is 1,500 to 3,000 mg/l. TDS concentration for the Rosebud Mine area ranges from 684 to 3,500 mg/l. There are no wells in the Rosebud Mine area to indicate that waters from spoils have contaminated or penetrated the interburden aquifer; however, power plant wastes appear to have caused an increase in TDS in the interburden aquifer near the townsite of Colstrip and at fly ash pond 210, located about two miles northwest of Colstrip (see discussion in next subsection on McKay coal). In 1980, water in some wells located below or near industrial ponds had TDS concentrations as high as 8,000 to 9,000 mg/l. Pre-mining levels were probably in the range of 500 to 3,500 mg/l (Botz, 1978).

Two wells, WI-100 and WI-104 (Figure II-5), located in the vicinity of Area C, Block I, have TDS concentrations of 1,655 and 2,700 mg/l, respectively. Concentrations of TDS for two interburden wells (WI-100 and WI-104) are probably typical of the range of concentrations for interburden aquifer water in Area C. The water can be characterized as calcium sulfate or magnesium sulfate water, depending on well location. Calcium and magnesium concentrations are generally in the range of 100 to 200 mg/l. Sodium concentrations typically range from 100 to 300

mg/l; however, because of faulting in the area and the suspected upward migration of deeper waters, it is probable that sodium sulfate waters are present in the interburden of Area C. In that case, sodium concentrations in these areas could be similar to that found in the sub-McKay, which has a sodium concentration as high as 700 mg/l.

f) McKay Coal

Two types of water are found in the McKay aquifer: a magnesium-sulfate and a sodium-sulfate type. Magnesium-sulfate water is found in most of Areas B and E, in the eastern and western portion of Area C, and in parts of Area D. Sodium sulfate waters are present in the central portion of Area C, in the northern portion of Area A, in Area D, and in one well at the Big Sky Mine. It is postulated that the sodium-type water is fault or coal flexure* controlled and results from upward migration of water along fracture zones from the sub-McKay aquifer or below, where such waters predominate.

The sodium-sulfate type water has calcium, magnesium, and sodium concentrations in the range of 15 to 100 mg/l, 6 to 75 mg/l, and 200 to 800 mg/l, respectively. Magnesium-sulfate type water has calcium, magnesium, and sodium concentrations in the range of 150 to 250 mg/l, 100 to 150 mg/l, and 100 to 200 mg/l, respectively. Bicarbonate and sulfate concentrations are similar to those found in all waters of the area: sulfate predominates, with a range of 200 to 1,500 mg/l, and bicarbonate varies from about 400 to 600 mg/l. Trace element concentrations are at or near detection levels.

Except where affected by spoils water, TDS concentrations range from about 500 to 2,500 mg/l. The description and concentration range cited above generally fits the situation in the Rosebud Mine area except for Area E, where wells S-04, S-08, and WM-127 (Figure II-5) indicate elevated TDS values with average concentrations of 5,725, 3,192, and 7,455 mg/l respectively (see Table 4 of Appendix B). The data for well SO-4 also appear to indicate an increase in TDS with time. The increase in TDS concentration over time indicates an external source of the salinity. The cyclic variation evident in well S-04 demonstrates the influence of precipitation on the recharge to wells and on the dissolved solids content. That is, wet years produce more recharge and usually lower salt concentrations than dry years. The time when these changes occur is dependent upon the amount of recharge from precipitation, the transmissivity of the aquifer, and the distance from the recharge area. This cyclic effect on TDS can be noted in data from other wells with sufficiently long periods of record.

g) Sub-McKay Aquifer

The majority of waters in the sub-McKay are of the sodium-sulfate type in the Rosebud Mine area. Water quality data is available for two wells in Area C, WD-101 and WD-102 (Figure II-5). Well WD-101 has water of a sodium-sulfate type and WD-102 yields magnesium-sulfate type water. Based on inspection of water quality in the McKay aquifer of Area C and the prevalence of faulting, one would expect the predominant water type in the sub-McKay to be of the sodium-sulfate type. TDS concentrations

in the sub-McKay waters of the Rosebud Mine area generally occur within the range of 1,000 to 3,000 mg/l. The only sub-McKay well in the Rosebud Mine area where some contamination is indicated is well 5-S (see Figure II-5), located adjacent to pond 951 at the Montana Power Company generating station in Colstrip, where TDS in December 1980 was 8,500 mg/l.

d. Groundwater Use

Groundwater withdrawn from the water-bearing strata in the Rosebud Mine area is primarily used for livestock. A few wells are also used for domestic water supply. Based on data presented by Van Voast (1977), approximately 36 percent of the domestic and stock wells are completed in the sub-McKay aquifer. The sub-McKay aquifer appears to be the most dependable water source because most of the wells in the study area are completed in this formation. Of the remaining stock water and domestic wells in the area, thirty percent are completed in the Rosebud overburden, ten percent are completed in the Rosebud coal, and less than ten percent are completed in the valley fill and McKay coal. Sixteen percent of the recorded wells in the study are either completed in other aquifers or well records cannot be located.

The McKay coal aquifer is rarely used as a water source because of its low productivity.

Ephemeral* springs are also used for livestock watering. Table B1-3 in the Technical Support Document lists the springs located in the hydrologic study area, while Plate B-2 illustrates their locations. Specific information on private wells and groundwater rights can also be found in the Technical Support Document (Tables B1-1 and B1-2, and Plate B-2).

2. Surface Water

The proposed Area C, Block I permit area is 4.5 square miles ($mi.^2$) (or 2,877 acres), and straddles the watershed divide between East Fork Armells Creek and Stocker Creek. Stocker Creek, with a drainage area of 26.1 $mi.^2$, flows into East Fork Armells Creek about three miles north of the Colstrip townsite. At the confluence of these two streams, the total drainage area is approximately 73.8 $mi.^2$. A total of 1,646 acres (2.6 $mi.^2$) of the permit area lies within the Stocker Creek drainage, and 1,231 acres (1.9 $mi.^2$) lay within the East Fork Armells Creek drainage (Figure II-16).

a. Drainage Basin Characteristics

East Fork Armells and Stocker Creeks both reflect the influence of bedrock and structural control. This influence is strongest in the headwaters of these creeks and decreases downstream, although some bedrock control of East Fork Armells Creek may continue throughout Area C. The areal extent of valley fill in both basins generally increases downstream, so that the main streams of East Fork Armells Creek and Stocker

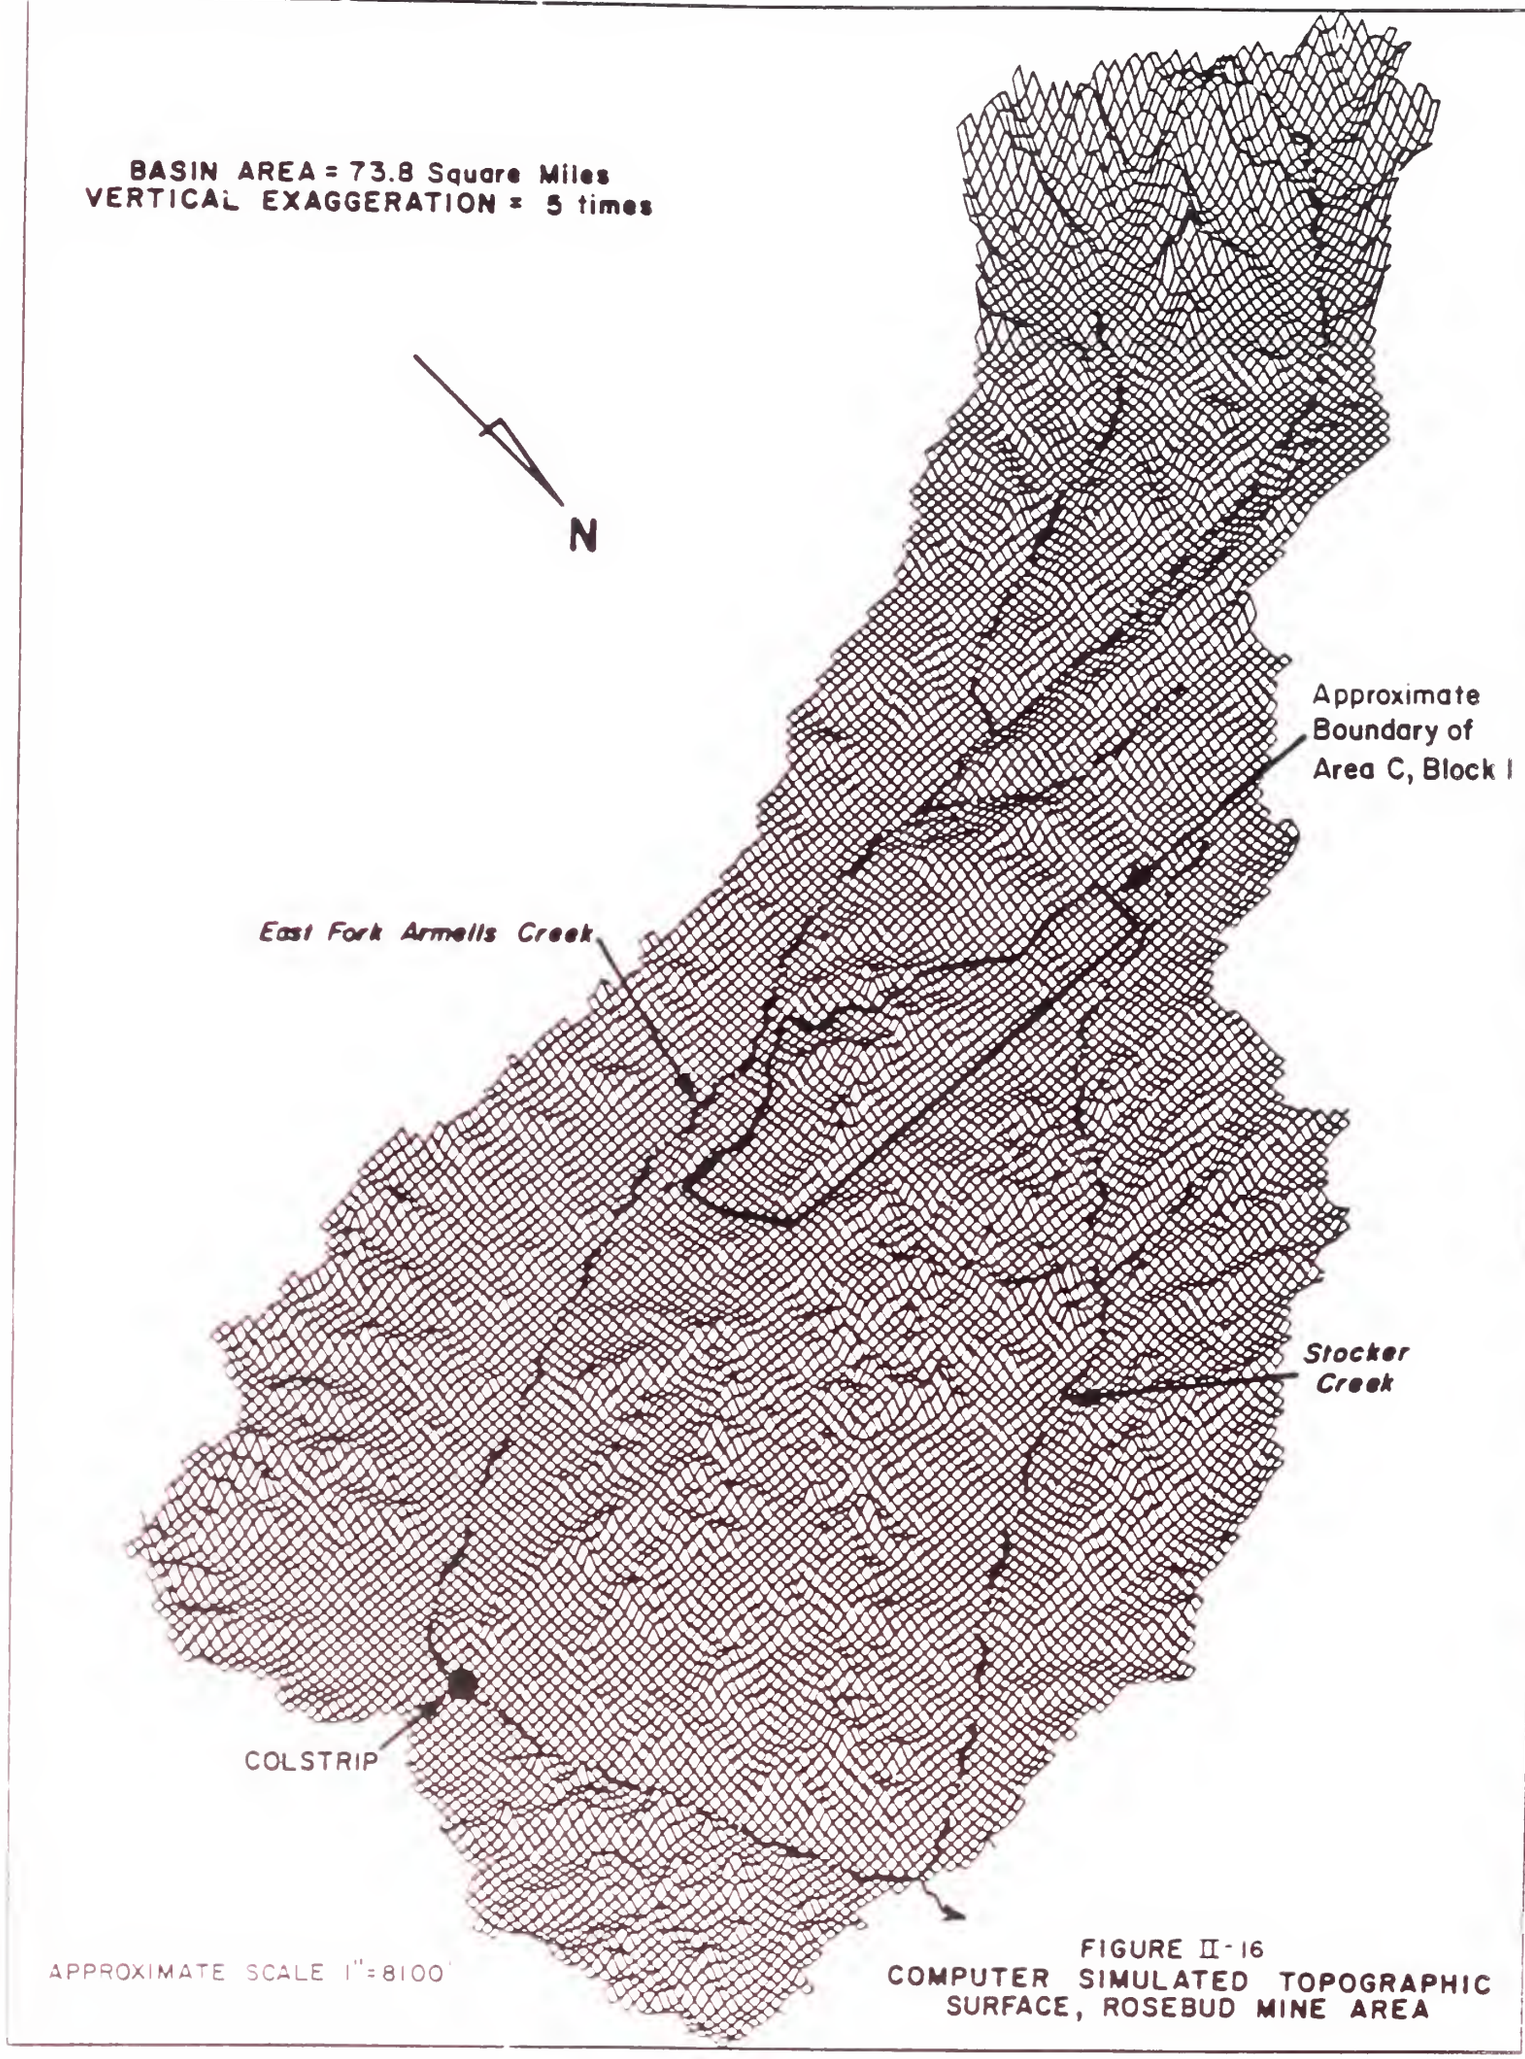


FIGURE II-16
COMPUTER SIMULATED TOPOGRAPHIC SURFACE, ROSEBUD MINE AREA

Exhibit 3

Creek flow within alluvial channels. The small, ephemeral* tributaries, however, are developed primarily on bedrock throughout the permit area.

Analysis of the drainage networks suggests that they are in equilibrium, where a relative balance between stream energy and transport exists. Both the main channels and tributaries of East Fork Armells Creek and Stocker Creek are entrenched, vegetated, and appear to be stable. Major entrenchment of the main streams of the basins is related to climatic change and base level* lowering since the Pleistocene Epoch. The stream network characteristics indicate that the tributary channels have generally adjusted to such long-term changes.

b. Stream Channel Characteristics

Through Area C, the main stem of East Fork Armells Creek is an alluvial channel, with sinuosities* ranging from 1.56 to 2.37, which increase progressively downstream. The longitudinal profile of the creek channel is concave and shows no clear evidence of current instability, neither as major slope changes nor as knickpoints*. In contrast, the ephemeral channels developed on the hill slopes of the upland areas have much straighter longitudinal profiles. Detailed surveys of 12 ephemeral channels in Area C (Appendix O, Western Energy Company Area C, Block I, Application for Surface Mining Permit) indicate that channel oversteepening due to deposition, followed by channel entrenchment, is common in these channels. Deposition and incision are also occurring in response to a change in base level from dam construction.

c. Drainage Basin Sediment Yields* and Landscape Stability

Calculations (see Section B.4 of the Technical Support Document) estimate that sediment yields within Area C are relatively low, ranging from 0.11 to 0.29 acre-feet per square mile per year, and are significantly below average basin yields, which range from 0.3 to 1.0 acre-feet per square mile per year that have been measured under similar geologic conditions in the High Plains region (e.g. Schumm and Lichty, 1965; Ringen et al., 1970). This reflects the predominance of landscape units (sediment source areas) with low or moderate sediment yields and the inefficiency of the vegetated ephemeral stream channels in transporting sediment.

The results of the geomorphic studies summarized above indicate that over relatively large areas (the scale of the East Fork Armells and Stocker Creeks drainage basins) and a long time frame of several hundred years, the landforms and drainage networks within Area C appear to be stable under existing environmental conditions. There is no evidence of widespread accelerated erosion. The major stream channels, although commonly entrenched, are vegetated and do not appear to be undergoing active gullying. However, at the scale of the small ephemeral drainages within Area C, there is some evidence (Technical Support Document, Section B.4) to suggest that these channels are inherently unstable.

d. Surface Water Flows

East Fork Armells Creek and Stocker Creek are intermittent* streams in Area C that flow in response to local and regional groundwater inflow over short reaches, as well as for short time periods in response to snowmelt and high-intensity precipitation events. The proposed permit area is drained by 14 ephemeral drainages tributary to East Fork Armells Creek and Stocker Creek. These tributaries also flow in response to late winter and early spring snowmelt and to late spring and early summer high-intensity precipitation events. Estimates of average annual discharges of 0.08 inches per year have been made by Van Voast (1977). This is equivalent to 315 acre-feet per year at the confluence of Stocker Creek and East Fork Armells Creek. Low flow in both drainages is zero. Although surface water gaging stations exist in the area (Appendix B, Table 5), flow records for Stocker Creek and East Fork Armells Creek are insufficient to accurately describe the magnitude and frequency of floods. However, techniques described by Parrett and Omang (1981) can be applied for estimating flood flows for the 2-, 5-, 10-, 25-, 50-, and 100-year floods. Estimates of flood peaks for Stocker Creek and East Fork Armells Creek are shown in Tables II-5 and II-6, respectively.

USGS continuous flow records for nearby areas were investigated for flow duration statistics. A relationship of the probability of flow occurrence per square mile of drainage area (Appendix B, Figure 1) was computed using these flow duration statistics. The computations demonstrated a close relationship between each stream, indicating a similarity of flow characteristics in the basins (Table II-7). This relationship was used to estimate flow statistics and to synthesize a probability of flow occurrence curve for East Fork Armells Creek below the confluence with Stocker Creek. The synthesized curve (Appendix B, Figure 2) indicates that for 90 percent of the days investigated, flow would be less than 2.5 cfs; for 80 percent of the days flow would be less than 1.0 cfs; and for 40 percent of the days, flow would be less than 0.01 cfs (essentially no flow). This curve illustrates that East Fork Armells Creek below the confluence with Stocker Creek has little or no natural base flow*.

e. Surface Water Quality

1) Streams

The proposed mining in Area C, Block I will occur in Sections 1, 2, 3, 4, 11, and 12 of T1N, R40E. The study area crosses the drainage divide between the north side tributaries of East Fork Armells Creek and the headwater areas of several tributaries on the south side of Stocker Creek. All tributaries in the area are ephemeral and dry for much of the year, flowing only in response to snowmelt and storm runoff (Surface Water Section 2.d). Data from surrounding areas on East Fork Armells and Stocker Creeks have been collected by Western Energy for a sufficient period of time and in a range of conditions to permit an adequate assessment of surface water quality. These data are used to supplement longer term data collected by the USGS on several streams in the area. Records

[1]These flows were derived from the other recorded flows in this table.

Exhibit 3

of complete chemical data collected on almost a monthly basis by the USGS are as follows:

Location	Period of Record
East Fork Armells Creek near Colstrip	January 1975 to May 1981
East Fork Armells Creek near Forsyth	October 1974 to October 1981
West Fork Armells Creek near Forsyth	November 1974 to June 1977
Rosebud Creek Near Colstrip	October 1974 to October 1981
Rosebud Creek above Pony Creek near Colstrip	October 1974 to November 1977
Cow Creek near Colstrip	October 1979 to May 1981

Concentrations of dissolved constituents are highly variable with respect to time in the East Fork Armells Creek and Stocker Creek basins in response to surface runoff events that dissolve minerals from the land surface. Discharge of subsurface water from valley fill, overburden, and possibly the Rosebud aquifer also influence stream quality. TDS concentrations range from about 200 mg/l at highest flows to about 6,500 mg/l at low base flow. TDS concentrations generally are in the range of 3,000 to 4,500 mg/l since low flows prevail for most of the year. Table 6, Appendix B lists TDS for samples collected by USGS for several sites in the Colstrip area. Stream discharge of the East Fork Armells Creek at Colstrip is also provided to show the relationship between conditions in the area at the time of sampling. Highest TDS concentrations in the range of 4,500 to 5,000 mg/l frequently occur during extreme low flow as a result of concentration from evaporation, transpiration, and biological activity as water passes slowly through pools along several reaches of the stream. These concentrations usually exceed those found in groundwaters of the valley fill and Rosebud aquifers along stream channels by 200 to 300 percent. Valley fill is the predominant source of recharge to streams at low flow, with water also contributed from the Rosebud aquifer in some areas (Groundwater Flow Section, Section 1.C).

Several areas in the East Fork Armells Creek drainage basin appear to have slightly higher TDS concentrations than those found in other stream segments in the Rosebud Mine area, and are presumed to be due to geologic differences. These areas are located approximately as follows: (a) the western half of Area C; and (b) the upper half of Stocker Creek basin (refer to Figure II-3). The evidence for these higher concentrations comes through an inspection of the data collected at surface water site SW-09 in the headwaters of East Fork Armells Creek, about one mile southwest of Area C, Block I; and from site SW-65 on Stocker Creek, about one mile northwest of the northwest of Area C, Block I. Data for West Fork Armells (SW-09 and SW-65, see Figure II-5) are provided in Table 7 of Appendix B. The soils in these areas contain higher proportionate amounts of clays and shales, which contain more soluble minerals than the sandy materials found in the remaining area (see discussions on Geology and Soils, Sections A and F). The surface waters of upper East Fork Armells Creek and Stocker Creek are very hard and have a very high salinity hazard most of the time, with TDS concentrations usually above 2,500 mg/l.

The surface waters in the Rosebud Mine area are a magnesium-sulfate type, with magnesium concentrations usually in the range of 200 to 500 mg/l and sulfate ranging from 1,500 to 3,000 mg/l. Calcium ranges from 200 to 300 mg/l, and sodium from 200 to 400 mg/l; bicarbonate concentrations are usually 400 to 550 mg/l. The relationships between TDS and specific conductance and between specific conductance and calcium, magnesium, sodium, and bicarbonate and sulfate for East Fork Armells Creek near Colstrip are shown in Figure 3, Appendix B.

The quality of water in the reach of East Fork Armells Creek upstream of Colstrip is quite similar to that shown on Figure 3 in Appendix B. Concentrations occurred at the high end of the range about 80 percent of the time. Sodium, magnesium, and sulfate constituents have a linear relationship with TDS at all levels; whereas, calcium and bicarbonate at these high levels reach a plateau, indicating saturation. The water is alkaline with pH in the range of 7.5 to 8.3. Nitrogen and phosphorus are usually low, with concentrations of a few tenths to a few hundredths milligram per liter, respectively. Fluoride concentration is generally 0.1 to 0.2 mg/l.

Trace metal concentrations are at or near the detection level of analytical methodology and constitute no problem, except for mercury concentrations found at several sampling points. For example, samples collected at SW-09, located about one mile southwest of Area C, Block 1, had mercury concentrations of 0.030 and 0.040 mg/l on several occasions. These values exceed the primary drinking water standard, and are believed to be inaccurate; probably resulting from sampling and/or laboratory error.

2) Ponds

The quality of water in ponds in the Rosebud Mine area that receive runoff from disturbed and reclaimed areas of strip mined lands is similar to that contained in the streams of the area. During spring runoff, concentrations will range from about 300 mg/l upward to about 2,000 mg/l. During summer and fall months, concentrations from about 2,000 to 4,000 mg/l will occur as a result of concentration from evaporation and possibly inflow from subsurface drainage. However, the latter is not considered to be a major factor. These concentrations are in a range suitable for stock watering purposes.

Several farm ponds in the area have water quality similar to that found in mining areas, except during late summer and fall they become slightly more concentrated, possibly due to farm activities or increased evapotranspiration rates.

3) Springs

Five springs are located in the Stocker Creek drainage of Area C. Two springs, SP-05 and SP-03 (Figure II-5), are located in Stocker Creek valley fill. The water is highly mineralized, with TDS concentrations of 5,160 and 4,930 mg/l. The remaining three springs (SP-01, SP-02, and SP-04 in Figure II-5) are located along the northern boundary of the Rosebud outcrop in the eastern portion of Area C. SP-01 is similar to

the valley fill springs in concentration with TDS of 5,310 mg/l. Spring SP-04 has a TDS of 3,240 mg/l and spring SP-02 is of relatively good quality, with TDS of 470 mg/l. Chemical data on quality of springs is contained in Table 8 of Appendix B.

The nitrate (NO_3) concentration of spring SP-02 far exceeds the normal for waters in the area, and probably results from organic material such as livestock wastes. Trace metal concentrations were at or below analytical detection levels, except for mercury in springs SP-01 and SP-04, which were 0.230 and 0.010 mg/l, respectively.

f. Surface Water Use

Surface water in East Fork Armells Creek is used for stock water and for flood irrigation downstream of Colstrip. There is no municipal, commercial, or irrigation use of surface water in the East Fork Armells Creek in the immediate vicinity of Colstrip townsite or the Rosebud Mine area. Stocker Creek surface flows are used for stock watering only.

Water is imported via a 29-mile pipeline from the Yellowstone River at a potential maximum rate of 10,000 gallons per minute, for municipal and commercial use by the town of Colstrip, mining activities, and the Montana Power Company power plant. A 112-acre surge pond with a capacity of 2,250 acre-feet stores this imported water. Seepage rates from the surge pond are estimated to range from 175 acre-feet per year (Technical Support Document, Section B.1), to 180 acre-feet per year (Hydrometrics, 1981).

The MPC power plant complex uses approximately 90 to 95 percent (or 7,700 acre-feet) of surge pond water per year. Approximately 85 percent of the water used at the power plant is lost to the atmosphere through evaporation from cooling processes and pond surfaces, some water is lost from pond seepage, and the balance is used mostly for road watering for dust suppression. During the months of March through October, current mine water use for dust suppression amounts to approximately 400 acre-feet of water. Most of this water is lost to the atmosphere through evaporation.

Municipal water use at Colstrip townsite is approximately 630 acre-feet of surge pond water per year, given the present (1980) population. Large amounts of this water are used during the summer months for household and community irrigation. Wastewaters from aproximately 1,150 housing units in Colstrip are treated and released into East Fork Armells Creek (Hydrometrics, 1981). The treated discharge ranges from 17 acre-feet per month to 23 acre-feet per month. This discharge is an additional potential contributing factor to a rise in the local water table, and may also have downstream effects.

The combined estimated seepage from the surge pond, the fly ash pond and the power plant ponds to the valley fill system has been determined to be 256 acre-feet per year (Hydrometrics, 1981). This along with an additional 210 acre-feet per year of effluent discharge from the sewage treatment plant represents a potentially significant addition to the

valley fill hydrologic system (combined surface and alluvial groundwater). Another addition is the seepage occurring from the unlined sewage lagoon; however, detailed monitoring of seepage has not been performed by the town of Colstrip to quantify the seepage volume.

The effects that the addition of more than 467 acre-feet per year of water to the valley fill system can vary. The most immediate and apparent effects would be the increase in downgradient water table elevations and the possible increase in stream flow in the valley fill system. Presently, flow in the valley fill system is approximately 1,180 acre-feet per year, 1,080 acre-feet per year is comprised of surface flow (Table II-7) and 80 acre-feet per year is groundwater flow (Hydrometrics, 1981). The 467 acre-feet per year being added represents 40% of the total flow in the system. However, evapotranspiration reduces this amount to 325 acre-feet per year, as determined by the two-dimensional model, or 28% of total flow in the valley fill system.

Another effect is the potential increase in groundwater discharge in other surface water drainage systems. Along this reach of the valley fill system, the adjacent bedrock units are being recharged by waters from the valley fill. This recharge will be manifested as an increase in the potential discharge to downgradient drainage systems. Those systems that are most likely to be affected are the Cow Creek and Hay Coulee systems. The effects that this increase in discharge has on the surface water use in these drainages cannot be quantified because background monitoring was not performed prior to the start of operations of the various ponds and the sewage treatment plant.

3. Hydrologic Budget

The hydrologic budget quantitatively defines inflow and outflow water and changes in storage within a specific hydrologic system.

The major components that will be discussed are:

- Precipitation (rain and snow)
- The role of vegetation in the hydrologic budget
- Evaporation from surface water sources
- Infiltration rates into the soil
- Soil-water budget
- Groundwater recharge
- Groundwater discharge

Other elements in the hydrologic budget, including surface runoff and groundwater flow, are discussed in Sections 1 and 2, respectively, of this EIS. In each component, both existing conditions and post-mining impacts will be addressed as presented by Western Energy in:

- Area C Permit Application (26.4.314)
- Comprehensive Mine Plan

a. Precipitation

The Colstrip area is influenced by a Continental-type climate, characterized by a wide range of average seasonal temperatures. The average annual precipitation at the Colstrip National Weather Service (NWS) station is 15.8 inches (Bison Engineering, 1981). Annual precipitation may deviate substantially from this long-term average, and the standard deviation of precipitation totals for the period 1928 to 1977 is 3.5. The extremes in total annual precipitation for the period 1970 to 1980 were 22.12 inches in 1978 and 7.66 inches in 1980.

Approximately 12 inches of this precipitation falls during the April to September growing season, with April, May, and June the wettest months. Summer precipitation occurs as showers and high-intensity thunderstorms.

From November to April, precipitation occurs predominantly in the form of snow. Due to the prevailing westerly winds, snow typically accumulates on the leeward (east) slopes of north-south oriented drainages and shallow depressions. These areas are potential sites of groundwater recharge when snowmelt occurs.

Little information is available on variations in precipitation that occur with topography. However, due to the prevailing westerly winds, it is anticipated that more precipitation will occur on the westerly slopes of the upland areas, particularly in the areas of more extreme relief to the west of the Colstrip study area.

b. The Role of Vegetation in the Hydrologic Budget
