

APPENDIX B: Baseline Water Resources Monitoring and Hydrogeological Investigations Report

Note: The Baseline Water Resource Monitoring and Hydrogeological Investigation Report summarizes data collected from 2011 through July 2015. Subsequent data is summarized in individual hydrological investigation reports Appendix B-1 (CTF Hydrological Investigation) and B-2 (Easter UIG Hydrological Investigation). Appendices B-A through B-D of this MOP Application include the water quality data, statistics, well logs, and aquifer test analysis conducted from 2011 through 2016.

BASELINE WATER RESOURCES MONITORING AND HYDROGEOLOGIC INVESTIGATIONS REPORT TINTINA RESOURCES BLACK BUTTE PROJECT

1.0 INTRODUCTION

Tintina Resources, Inc.'s (Tintina) has conducted both water resource baseline monitoring and hydrologic investigations for the Black Butte Copper Project located north of White Sulphur Springs, Montana (Figure 1). These investigations were conducted in support of permitting activities for the exploration and development of copper-bearing massive sulfide deposits within the lower Newland Formation. This report summarizes the results to date from the baseline monitoring program and hydrologic investigations.

Baseline monitoring for this project was initiated in May of 2011 and entails measurement of flow, water levels, and water quality at surface water, groundwater, and spring and seep monitoring sites in the project area. Quarterly sampling is conducted at 11 surface water sites (Figure 2) and 11 monitoring wells (Figure 3). Surface water data collection consists of baseline water quality sampling and analysis, and flow measurements. Surface water monitoring at sites on Sheep Creek has been conducted on a bi-weekly/weekly schedule during spring run-off since 2013; monthly monitoring has been conducted at these sites since 2014. Spring and seep monitoring is also conducted annually and includes monitoring of flow and field parameters at 16 springs; 11 of the spring monitoring sites have been sampled for water quality analysis (Figure 4). Field parameters are also monitored annually at ten seep locations. Groundwater monitoring is conducted quarterly at 12 monitoring well sites, and static water levels are measured quarterly at 22 additional test wells and piezometer sites. Water quality data have also been collected at ten test wells during site investigations (PW series wells shown on Figure 3); however, these wells are not routinely monitored during baseline monitoring events. Table 1 summarizes the type of baseline data available and period of record at each of the sites.

In addition to baseline monitoring, a number of groundwater investigations have been conducted to characterize hydrostratigraphic units in the project area (Hydrometrics, 2012c, 2013a, and 2015). In addition, investigations have been conducted of groundwater/surface water interactions for a possible Land Application Disposal (LAD) area (Hydrometrics, 2013a), and two synoptic surveys were conducted on Sheep Creek between Little Sheep Creek and downgradient monitoring site SW-1.

1.1 HYDROLOGIC SETTING

1.1.1 Surface Water

The project area is in the upper portion of the Sheep Creek drainage, a tributary to the Smith River, which in turn is a tributary of the Missouri River (Figure 1). Sheep Creek is a fifth order stream draining a total of approximately 194 square miles. Sheep Creek originates in the Little Belt Mountains at an elevation of about 7,400 feet and discharges to the Smith River approximately 34 river miles to the west at an elevation of 4,380 feet. The project area is located in the approximate upper third of the drainage. The project area is approximately 19 river miles above the confluence with the Smith River. Sheep Creek is a high quality stream that flows in a meandering channel through a broad alluvial valley upstream of the project site but enters a constricted bedrock canyon just downstream. It is used principally for stock water and fishing (RMI, 2010).

Primary tributaries to Sheep Creek in the immediate project area include Little Sheep Creek and Coon Creek (Figure 5). Little Sheep Creek is located southeast of the project area and converges with an unnamed tributary (referred to here as Brush Creek) approximately half a mile south of Strawberry Butte. Coon Creek follows Butte Creek Road east of Black Butte and joins Sheep Creek at the head of a canyon located almost one mile northwest of Strawberry Butte (Figure 5). To the west of Black Butte is Black Butte Creek, also a tributary to Sheep Creek. Black Butte Creek flows to the northwest and joins Sheep Creek approximately seven miles to the west-northwest of Black Butte. There is a small unnamed tributary that joins Sheep Creek on the north side of Strawberry Butte that collects water from springs on the north flank of the Sheep Creek Valley. Another small un-named

Figure 5
Major Creeks and Tributaries
Black Butte Copper Project
Meagher County, Montana

tributary flows westward from the northern side of Black Butte into Black Butte Creek. Flow in these tributary drainages is only perennial on their lower reaches and ephemeral upstream.

The United States Geological Survey (USGS) historically operated a gaging station on Sheep Creek (USGS 06077000) that was located approximately four miles upstream of the project site (Figure 5). Stream flow in Sheep Creek was gaged at this site from 1941 through 1978, and the USGS reports average monthly flows ranging from approximately 9 cfs to 115 cfs. A hydrograph of the average daily discharge at the former Sheep Creek gaging station is shown on Figure 6. The nearest active USGS gaging stations (USGS 06076690 and 06077200) are located on the Smith River just above the confluence with Sheep Creek near Fort Logan and just below the confluence with Sheep Creek and Eagle Creek (Figure 1). The upstream gaging station (06076690) was monitored continuously from October 1977 to the end of September 1996. The site has been operated periodically since October 2006 with seasonal operation (roughly April through October) from 2008 to 2011 and continuous operation since August 2014. The downstream gaging station (06077200) has run continuously since October 1, 1996. Average monthly flows on the Smith River at the upstream gaging site range from 18 to 3200 cfs and at the downstream gaging site from 30 to 3800 cfs. The percentage of flow from Sheep Creek is unknown as there are additional tributary drainages between the two USGS gaging stations.

The Holmstrom Ditch is another significant hydrologic feature on Sheep Creek. It is a diversion ditch that was constructed by the Holmstrom Land Company in 1935 to divert Sheep Creek water for irrigation use. The diversion point to the ditch is just downstream of the former USGS-SC1 gaging station (Figure 5). While the Holmstrom Land Company continues to use the ditch for seasonal irrigation diversions, the ditch is also used by the Newlan Creek Water District as a source of water for the Newlan Reservoir.

BASELINE WATER RESOURCES MONITORING AND HYDROGEOLOGIC INVESTIGATIONS RESULTS FOR THE TINTINA RESOURCES BLACK BUTTE PROJECT	MEAN DAILY FLOW HYDROGRAPH AT USGS SITE ON SHEEP CREEK	FIGURE
		6

1.1.2 Groundwater

Groundwater is present in the project area in Quaternary alluvial deposits that occupy the axes of the major drainages, in colluvium deposits and highly weathered shallow bedrock that flank these drainages, and in the underlying more competent bedrock formations. In the immediate project area, bedrock is primarily relatively low permeable dolomitic and silicic shales of the Newland Formation. A review of available information in the Groundwater Information Center (GWIC) database (Montana Bureau of Mines and Geology; MBMG) indicates wells completed in bedrock in the project area are generally low yielding with reported yields of 4 to 50 gpm (median 12 gpm). The bedrock wells within the area are generally completed at depth greater than 100 feet below ground surface (one well completed above 100 feet; range 52 to 500 feet, median 191 feet). There is limited historical information on the hydrogeology of the project area; however, artesian flow has been noted during previous exploration activities (RMI, 2010) in some exploration drill holes completed in the deeper bedrock units underlying the Sheep Creek Valley. In general, artesian flows were noted in core holes that were collared in the Sheep Creek Valley and penetrated through the VVF into the LCZ, flows were observed after the holes were left open for many weeks/months. Flow rates from these core holes were very low, and when they were observed the holes were plugged at depth to seal off the groundwater in the LCZ (Zieg, 2016).

2.0 BASELINE MONITORING

The surface water and groundwater monitoring discussed below establish baseline stream flows, groundwater potentiometric elevations, and water quality in the project area. Hydrometrics, Inc. (Hydrometrics) of Helena, MT has conducted the baseline surface water and groundwater monitoring for the Black Butte Copper Project since the sampling was initiated in 2011. Water resource monitoring is conducted in accordance with the 2013 Field Sampling and Analysis Plan (Hydrometrics, 2013b). Surface water and groundwater quality samples are submitted to Energy Laboratories in Helena, MT for analyses of physical parameters, common constituents, nutrients, and a comprehensive suite of trace constituents as listed in Tables 2 and 3, respectively. With the exception of aluminum, trace constituents are analyzed for the total recoverable fraction for surface water samples; aluminum is analyzed for the dissolved fraction. All trace constituents for groundwater samples are analyzed for the dissolved fraction. In addition to the laboratory analysis, hardness was calculated based on the concentration of calcium and magnesium. During some monitoring events bicarbonate and carbonate concentrations were reported by the laboratory, these results are included in the water quality databases (Appendix A). This report summarizes the results of groundwater and surface water monitoring conducted through July 2015.

2.1 SURFACE WATER MONITORING

Eleven surface water stations have been established as baseline monitoring sites (Figure 2). Flow, stage, and field parameters (temperature, pH, and specific conductivity (SC)) are monitored quarterly at all of these sites. Water quality samples are collected at six of the sites during quarterly monitoring. Monitoring was initiated at these sites in May 2011 with subsequent quarterly monitoring events scheduled in the months of August, November, March, and May of each year. In July 2011, surface water samples were collected from two sites (G-1 and G-2) downgradient of where gossan outcropped in the streambed to evaluate if exposed gossan affected surface water quality. This was a one-time monitoring event and these sites are not included as part of the long-term baseline monitoring program. Monthly surface water monitoring has been conducted at sites on Sheep Creek since 2014.

2.1.1 Stream Flows

Seasonal flow measurements have been taken at Sheep Creek upstream of the project area (SW-2) and downstream (SW-1) since baseline monitoring was initiated in May 2011. High flow season (May/June) stream flows are difficult to accurately measure in Sheep Creek due to water depths and high flow velocities, but estimated flows during May/June quarterly sampling rounds on Sheep Creek have ranged from approximately 100 cfs up to 600 cfs. In contrast, baseflows in late summer/fall monitoring events have ranged from 10 to 30 cfs at upstream monitoring site SW-2 and 15 to 34 cfs at downstream monitoring site SW-1. Flow measurements typically increase by 25% to 50% from SW-2 to SW-1. In addition to the flow monitoring at baseline monitoring sites, stream flow has also been measured monthly at the former upstream USGS gaging site since May 2014 with concurrent measurements at SW-1 and SW-2 to allow correlation of the stream flows between the sites. A comparison of stream flow monitoring results is shown in Figure 7. Streamflow increases between the upstream USGS-SC1 site and downstream SW-1 by a factor of up to 2.5 during spring runoff and then gradually decreases becoming nearly equal in late August when tributary inflows downstream of USGS-SC1 are diverted for irrigation. Downstream flows increase after irrigation season ends and the flow measurements show approximately 50% increase in streamflow between USGS-SC-1 and SW-1 during baseflow periods in early spring.

In November 2012, Tintina installed a temporary stilling well with a transducer to develop detailed seasonal baseline data on water level stage and discharge fluctuations in Sheep Creek. The stilling well is located at monitoring site SW-1 and is just north of the location where Sheep Creek enters the narrow bedrock canyon below the project site. It is identified as the Sheep Creek Gaging Station on Figure 2. Baseline stage and flow measurements from SW-1 were used to generate a stage/discharge rating curve for the Sheep Creek Gaging station that allow water level records from the gauging stations to be converted to stream flows (Figure 8). The SW-1 hydrograph presented on Figure 9 shows seasonal streamflows in excess of 100 cfs extending from mid-May-through mid-June in Sheep Creek with peak flows of 200 cfs to over 800 cfs. Stream flows in Sheep Creek decline rapidly in late June/early July with average monthly flows of 15 cfs to 30 cfs by late summer. By late

winter, gauging data indicate steady state base flow in Sheep Creek is approximately 15 cfs at SW-1.

Flow monitoring results for each of the surface water monitoring sites is summarized in Table 4, and stream flow data for each of the sites is tabulated in the monitoring database in Appendix A.

TABLE 4. SUMMARY OF STREAM FLOW MONITORING DATA

Monitoring Station	Stream	March	May/June	August/Nov
		Measured Stream Flow (cfs)		
SW-1	Sheep Ck	30-41	111-613	10-34
SW-2	Sheep Ck	Frozen	98-250	7-30
SW-3	Coon Ck	0.22	0.3-5	0.08-0.34
SW-4	Coon Ck	0.16	0.2-2	0.01-0.4
SW-6	Unnamed tributary to Black Butte Ck	0.04-0.26	0.5-4	0.17-0.33
SW-7	Unnamed tributary to Black Butte Ck	0-0.4	0-0.3	0.001-0.01
SW-8	Little Sheep Ck	1.7	1-9	0.2-1
SW-9	Black Butte Ck	0.3-1.8	2.3-12.7	0.3-0.8
SW-10	Black Butte Ck	Frozen	1.7-15.2	0.3-0.5
SW-11	Black Butte Ck	1.0-2.9	1.6-21.4	0.4-1.0

The observed increase in stream flow in Sheep Creek between SW-2 and SW-1 appears to be largely accounted for during high flow season by inflow from Little Sheep Creek; however, during baseflow periods the increase is not entirely accounted for by Little Sheep Creek or other monitored tributaries. The increase is likely attributable to groundwater discharge and/or inflow from unmonitored springs and tributaries on Castle Mountain property to the north of Sheep Creek.

2.1.2 Surface Water Quality

Water quality data for each of the surface water monitoring sites is presented in Appendix A and water quality statistics for individual sites are compiled in Appendix B. Surface water results show neutral to slightly alkaline pH values (6.8 to 8.6), and low to moderate specific

conductance (49 to 487 $\mu\text{mhos/cm}$). A few lower field pH readings (5.3 to 6.4) were reported at SW-1 during winter sampling events. Spot checks of pH at the lab indicated sample pHs above 8, which is consistent with readings from other sampling rounds at this site and with data from SW-2 and USGS-SC1. Discussions with the instrument manufacturer verified that the probe is susceptible to error at low temperatures; therefore, these results have been flagged as anomalous in the database (Appendix A).

Major ion chemistry is dominated by calcium and bicarbonate. With the exception of SW-5, which only has flow during spring runoff, hardness ranges from approximately 73 to 256 mg/L. Metals data show some infrequent excursions above DEQ-7 water quality standards for selected metals (aluminum and iron) during high runoff events. Samples collected from gossan sites G-1 and G-2 were similar to the long-term water quality monitoring sites and therefore they were not added to the long-term baseline water resource monitoring program. Surface water standard exceedances were observed for the following constituents:

- Chronic aquatic criteria for total recoverable iron (1 mg/L) is exceeded during peak runoff periods at all sites except SW-6 and SW-11 (2011) and SW-3 (2012).
- Chronic aquatic criteria for dissolved aluminum (0.087 mg/L) is often exceeded during periods of high runoff in Sheep Creek (SW-1, SW-2, and USGS SC-1) and in Black Butte Creek (SW-11).
- In addition, the human health surface water standard for thallium of 0.00024 mg/L was exceeded at SW-3 during three separate monitoring events in 2011.

The iron and aluminum exceedances are likely related to increased turbidity during periods of snowmelt and high runoff.

2.2 GROUNDWATER

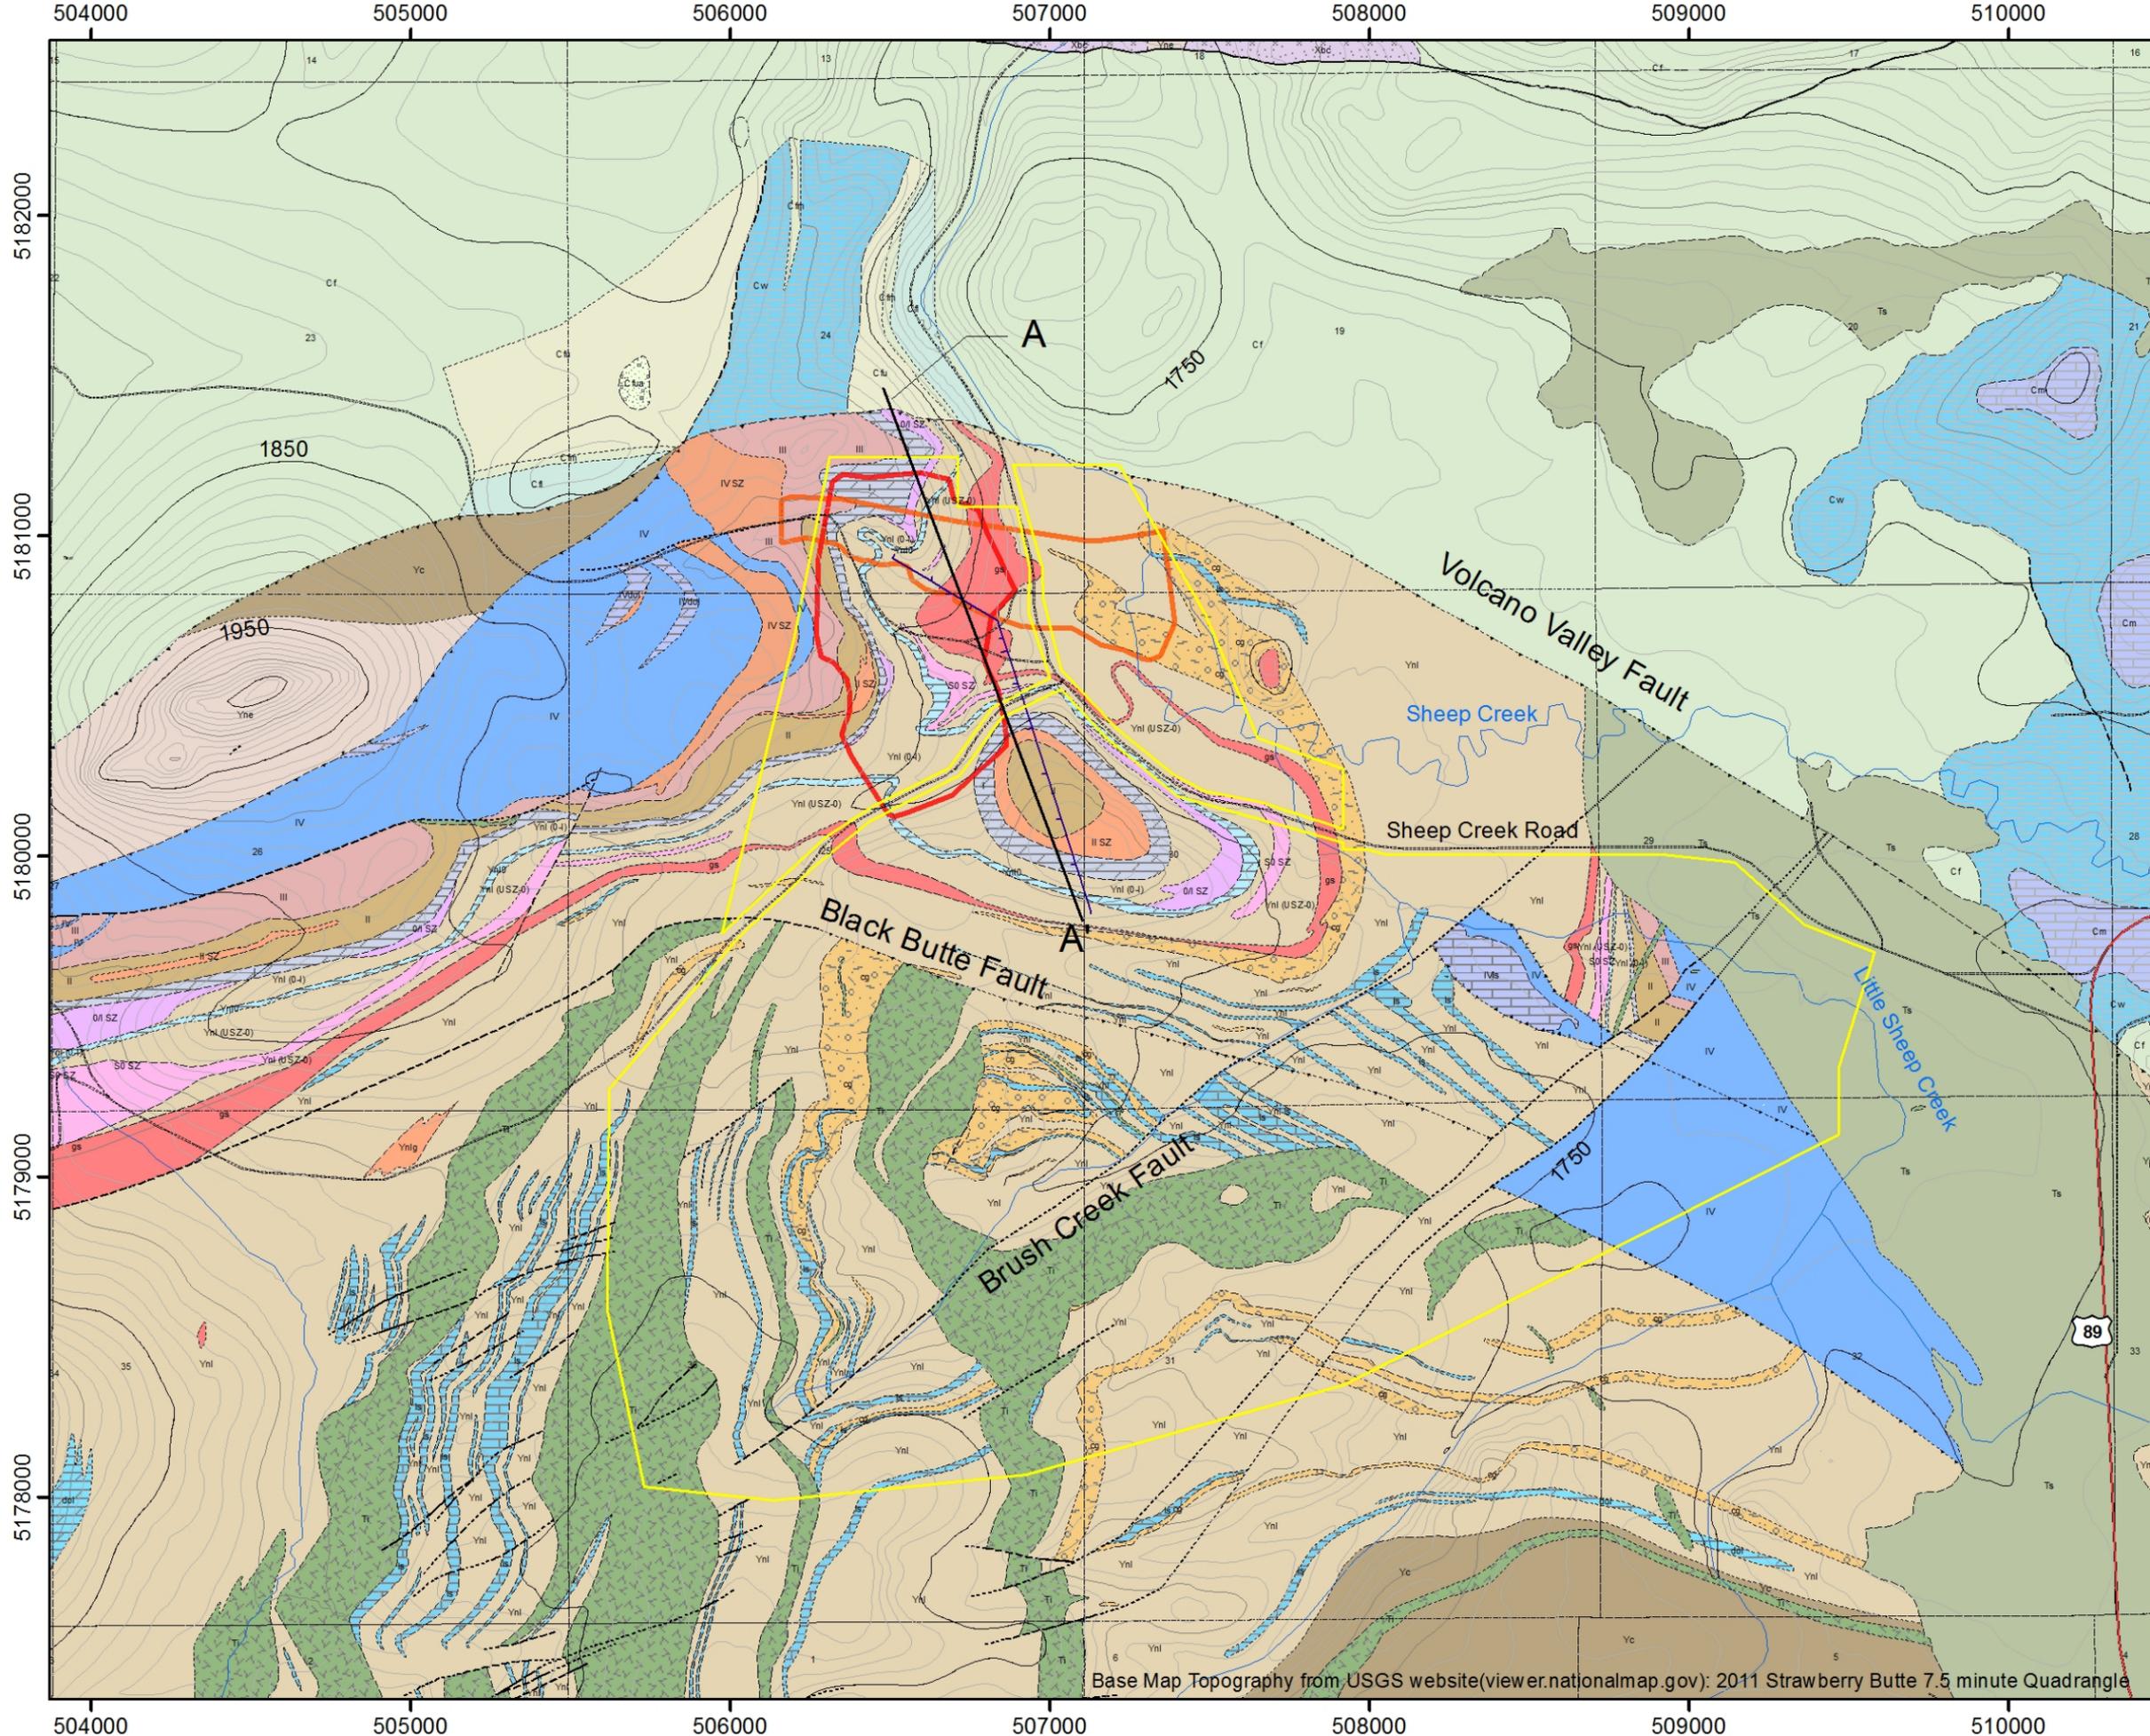

2.2.1 Geology/Hydrostratigraphy

The geology and subsurface stratigraphy within the project area has been evaluated based on geologic mapping and extensive exploratory drilling. A geologic map of the project area is

shown in Figure 10 and a geologic cross section through the project area is shown in Figure 11. Alluvial deposits are present beneath the stream channels and along the axis of the drainages. The mine will penetrate a thick sequence of dolomitic and silicic shales of the Proterozoic Newland Formation that dips gently to the southeast in the project area.

The project area is bounded to the north by a prominent northeast trending thrust fault known as the Volcano Valley Fault (VVF). Paleozoic Flathead sandstone is exposed at the surface on the north side of the VVF and lies unconformably over Proterozoic Chamberlain shales, Neihart quartzite and Precambrian crystalline basement rock (Figure 11). A separate northeast verging segment of the VVF thrust fault called the Black Butte Fault (BBF) is located south of the ore body (Figure 10). The area between the Black Butte fault and the VVF contains all of the known copper resources within the Project area.

Figure 12 shows the principal stratigraphic units that will be encountered during development of the Johnny Lee deposits. There are upper (UCZ) and lower (LCZ) ore zones within the Johnny Lee copper-cobalt deposit hosted within the Upper and Lower Sulfide Zones (USZ, LSZ) of the lower Newland Formation. The upper ore zone lies at a depth of approximately 250 to 350 feet below ground surface and is overlain by shale and dolostone (Ynl A), and dolomite (Ynl O) interbeds. The upper ore zone is underlain by the lower Newland shale and conglomerate (Ynl B). These units are cut by the southward dipping VVF to the north. A thin slice of the lower Newland Formation lies below the VVF and contains the lower ore zone, which is at a depth of approximately 1,300 to 1,500 feet below groundwater surface. The Lower Ore Zone and Lower Newland shales are just above the contact with the Chamberlain Formation and are cut to the north by the Buttress Fault, a Precambrian normal fault (Figure 11). The Buttress fault does not extend to the surface but is truncated by the VVF (Figure 11) and therefore does not have a surface expression on the geologic map in Figure 10.

Monitoring wells and test wells have been completed within the shallow and deep stratigraphic units described above to define baseline water levels, groundwater flow directions and groundwater quality within the project area. A series of paired monitoring wells (MW-1A,-1B, MW-2A, -2B, MW-4A, -4B, and MW-6A, -6B) were installed between 2011 and 2013 to document baseline conditions within the unconsolidated Quaternary/Tertiary clayey gravel deposits and in the underlying shallow bedrock groundwater system (Figure 3). Monitoring well MW-3 was completed in November 2011 near the proposed terminus of the exploration decline within the UCZ. Paired wells MW-6A and MW-6B and two single wells (MW-7 and MW-8) were completed as groundwater quality and water level monitoring wells to document baseline water quality in the vicinity of the proposed underground LAD/infiltration system where treated mine water will be discharged. MW-6A is completed in shallow alluvial gravels, and MW-6B, MW-7, and

MW-8 are completed in shallow YNL-0 dolostone bedrock. In 2014, an additional monitoring well, MW-9, was installed in the YNL-A zone above the sulfide and ore zones as a monitoring point to assess the effects of ore zone dewatering on overlying units during mine development.

In addition to these monitoring wells, 10 test wells (PW-1 through PW-10) have been installed for aquifer testing to provide information on both the hydrologic characteristics and water quality within representative stratigraphic units. A schematic diagram depicting completion units for all of the monitoring and test wells is shown in Figure 10. Water level and water quality data have been collected at the PW series test wells during aquifer testing; however, the test wells are not routinely monitored during quarterly baseline monitoring events. Well completion data for all of the monitoring wells and test wells is summarized in Table 5, water quality data is included in Appendix A and water quality statistics for individual sites are compiled in Appendix B. Well logs are included in Appendix C.

Twelve piezometers are used to monitor the groundwater levels in the alluvial/colluvial systems of Sheep Creek, Coon Creek, and Dry Creek. Piezometers PZ-1 through PZ-5, PZ-8, PZ-9, and PZ-11 are completed in the Sheep Creek alluvial system. Paired piezometers PZ-7A/-7B are located near the headwaters of Coon Creek and PZ-12 located near MW-3 adjacent to Coon Creek. PZ-12 is located in the Dry Creek drainage south of wells MW-9, PW-9, and PW-10. The completion details of each piezometer are included in Table 5.

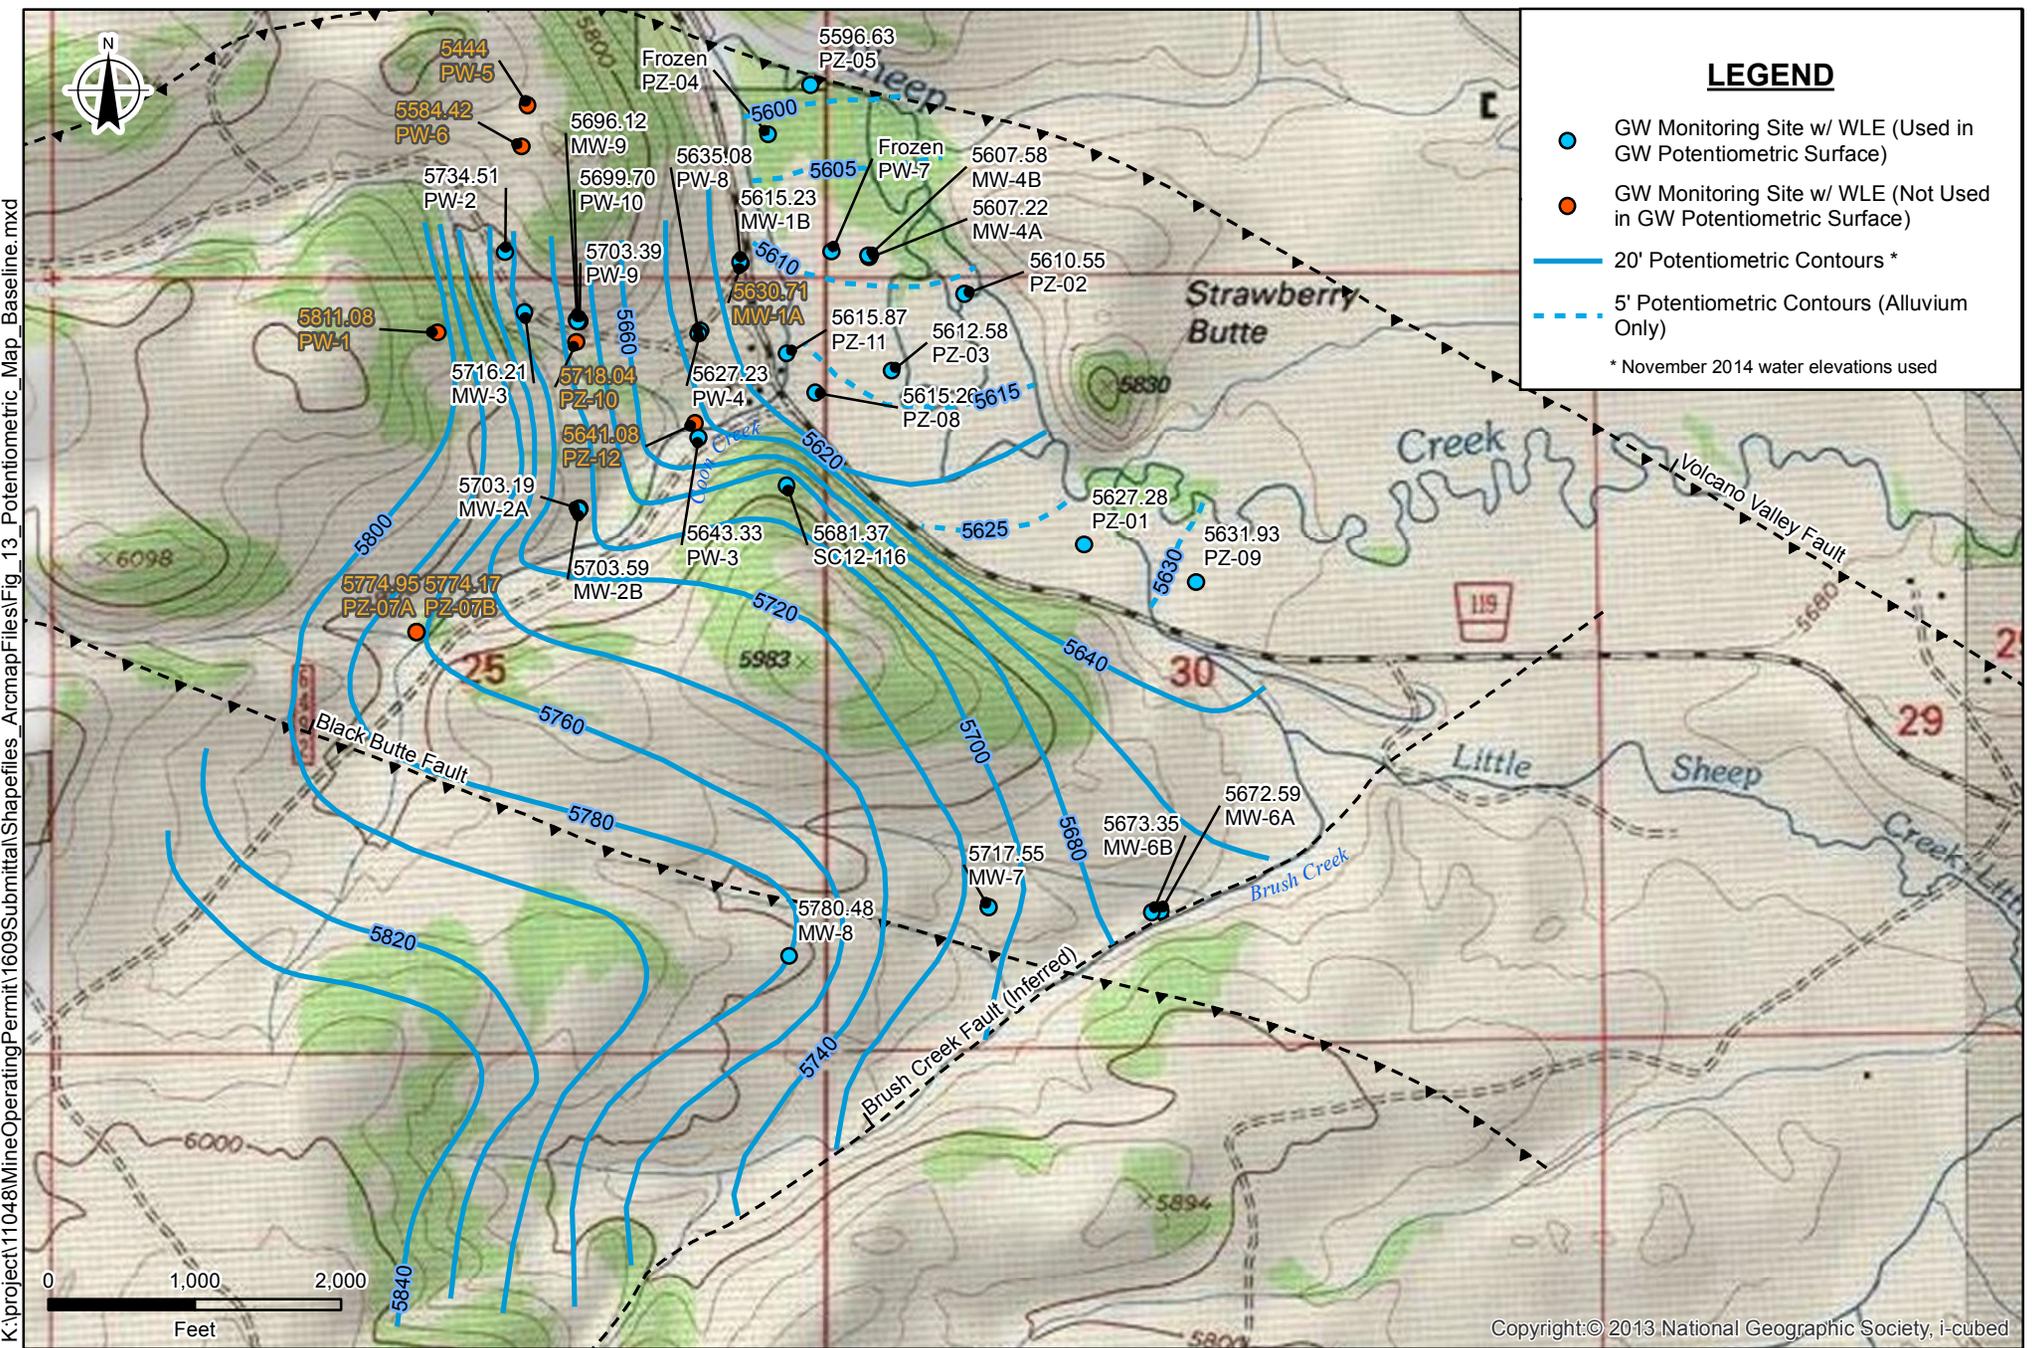

2.2.2 Groundwater Flow Directions

Water level data from the November 2014 sampling round are compiled in Figure 13; the potentiometric surface shows an eastward trending flow direction in the bedrock groundwater system within the project area that is consistent with the general topographic trend in the area. The potentiometric contours of the bedrock hydrologic system indicate an average hydraulic gradient of approximately 0.08. Groundwater in the Sheep Creek alluvium generally flows parallel to the creek; northwest and then turns to the north as Sheep Creek

Figure 13
Potentiometric Surface Map
Black Butte Copper Project
Meagher County, Montana

bends to the north around Strawberry Butte (Figure 13). The groundwater flow continues to flow north towards Sheep Creek as the creek crosses the northern extents of the alluvial system as it enters a small canyon. The hydraulic gradient in the alluvial system is relatively flat (0.008) through most of the monitoring area; the gradient increases slightly to 0.013 in the northern portion of the valley. Water level elevations at PZ-04 and PZ-05 (located in the northern portion of the alluvial valley) are typically near or above the ground surface throughout the year. The increased gradient and near surface water level elevations in this area are a potential indicator that the alluvial groundwater system is discharging to surface water as the alluvium pinches out where Sheep Creek flows into a canyon.

With the exception of two well pairs, most sites show upward hydraulic gradients. Paired wells MW-1A and MW-1B completed in the highly weathered shallow bedrock and the deeper more competent bedrock have a strong downward hydraulic gradient during all monitoring events with a head differential between the two wells of 15 to 18 feet indicating a shallow perched groundwater system. PZ-07A and PZ-07B also have a downward hydraulic gradient indicating that the surficial groundwater system associated with the headwaters of Coon Creek is also likely a perched system that is not fed by the deeper bedrock aquifer in this area.

In contrast, other well pairs (MW-2A/2B, MW-4A/4B, and MW-6A/6B) all show upward hydraulic gradients. Paired wells MW-2A and MW-2B, show an upward hydraulic gradient between the YNL-A groundwater system and the shallower highly weathered bedrock system with a head difference of 0.30 feet. Paired wells MW-4A and MW-4B show an upward hydraulic gradient between the bedrock aquifer and the Sheep Creek alluvium. Paired wells MW-6A and MW-6B adjacent to Brush Creek also show an upward gradient with a head difference of 0.76 feet between the shallow YNL-0 dolomitic shale and the overlying colluvium/alluvial system adjacent to Brush Creek. Artesian conditions at well PW-7 also indicate an upward hydraulic gradient in this area.

In addition to the paired wells discussed above, there is one set of triplet wells on site, MW-9, PW-9, and PW-10, which are completed in the YNL-A, UCZ, and YNL-B,

respectively. The May 2015 water levels elevations at these wells show a large upward gradient from the UCZ (PW-9) to the overlying YNL-A (with a head difference of 7.27 feet) and a large downward gradient to the underlying YNL-B (with a head difference of 3.69 feet).

2.2.3 Groundwater Quality

Field data and analytical water quality results for groundwater monitoring sites are included in Appendix A. Groundwater in the shallow alluvial wells and in shallow bedrock wells is calcium/magnesium bicarbonate type water with near neutral pH and moderately low dissolved solids. One exception is well MW-1B, which has calcium/magnesium sulfate type water with a lower pH range (6.02 to 6.51 s.u.) and moderate dissolved solids (336 to 425 mg/L). The water quality at MW-1B is similar to MW-3 and test well PW-4, both of which are completed in the sulfide ore zone.

Wells completed in shallow unconsolidated overburden include MW-1A, MW-4A, and MW-6A. These wells have neutral pH water (6.24 to 7.66 s.u.) with low to non-detectable concentrations of dissolved metals. MW-1A, however, periodically exhibits variable water quality with some excursions of arsenic, barium, iron, lead, manganese, and thallium above the Human Health standards. Well MW-1A is screened in fine-grained sediments and has very high turbidity present in the water during sampling events. Monitoring events where metals are detected at higher concentrations at this well may reflect breakthrough of particulate through the filters due to the very high turbidity.

Wells completed in bedrock above the sulfide ore zone include MW-2A and MW-2B, MW-4B, MW-6B, MW-7, MW-8, MW-9, and test wells PW-1, PW-2, and PW-3. Dissolved trace constituents that are present at detectable concentrations in the shallow bedrock wells include arsenic, barium, iron, manganese, strontium, thallium, and uranium. Water quality at test wells PW-1, PW-2, and PW-3 exceed the secondary drinking water standards for iron (0.3 mg/L) and manganese (0.05 mg/L) (neither of these secondary standards are currently listed numeric water quality standards in Montana's October 2012 Circular DEQ-7), and the concentration of thallium at MW-2B (0.0024-0.004 mg/L) was at or exceeds the human

health standard of 0.00024 mg/L. Thallium concentrations at the other shallow bedrock wells are below regulatory limits. All other parameters in the shallow aquifer meet applicable regulatory limits.

While thallium is also present at detectable concentrations in MW-3 and PW-4, it does not exceed the human health standard. All of the ore zone wells exceed the secondary drinking water standard for iron, and MW-1B and PW-4 also exceed the secondary drinking water standard for manganese (neither of these secondary standards are currently listed numeric water quality standards in Montana's October 2012 Circular DEQ-7).

Wells completed in the sulfide ore zone (MW-3, PW-4, PW-9) have the highest concentrations of dissolved solids and sulfate compared to the other wells. As previously discussed, MW-1B has similar water quality to these ore zone wells. The pH of water at these ore zone wells ranges from 6.04 to 7.31, which is slightly lower than other wells. Dissolved trace constituents that are present at detectable concentrations in the ore zone wells include antimony, arsenic, barium, cobalt (MW-1B only), iron, lead, manganese, mercury, molybdenum, nickel, strontium, thallium, uranium, and zinc. Strontium concentrations are elevated (8.08 to 16.2 mg/L) at MW-3 and PW-4 and exceed the human health standard of 4 mg/L. Arsenic concentrations at MW-1B, MW-3, and PW-4 range from 0.054 mg/L to 0.09 mg/L and exceed the human health standard of 0.010 mg/L. Arsenic speciation of samples from MW-1B and MW-3 indicate that the majority of the arsenic is present in reduced form as As (III). Concentrations of thallium at MW-1B (0.013 mg/L) also exceed the human health groundwater standard of 0.002 mg/L.

The analytical results from PW-7 (completed in the LCZ) indicate a sodium/potassium bicarbonate type water with highly basic pH (10.77 to 11.58 s.u.), higher concentrations of chloride and lower concentrations of sulfate than other wells on site. Trace constituents detected above the reporting limit include aluminum, antimony, arsenic barium, molybdenum, selenium, strontium, and zinc. Dissolved aluminum concentrations (0.187 to 1.03 mg/L) were much higher than observed at other wells on the site. Antimony was the only trace constituent that exceeded the groundwater human health standard. This sample

provides an initial assessment of the water quality in PW-7. However, the well did not produce sufficient water to allow for field parameter stabilization and drill mud was found in the well during the initial water level measurements and in subsequent monitoring events. These factors along with the atypical water quality including elevated aluminum, chloride, and sodium suggest the water quality from PW-7 may be impacted from drilling muds and fluids.

2.3 SEEPS AND SPRINGS DELINEATION

As a part of the initial water resource evaluation, nine seeps and 13 springs in the Project area have been identified, mapped, and some sampled for water quality and flow as a part of an inventory completed in 2011 (Hydrometrics, 2012b). A second series of flow measurements and water quality samples of seeps and springs was collected during July 2012. A number of springs discharge along the Volcano Valley Fault where the Flathead Quartzite is in contact with the Newland formation (Chen-Northern, 1989). Seeps and springs are identified on Figure 4.

The majority of the identified sites consist of small springs or seeps located in ephemeral channels in the headwaters of small unnamed tributaries. These springs form small boggy areas with limited flow and generally re-infiltrate within a few hundred feet downstream. A number of these springs have been developed for stock watering (indicated by a DS designator in Figure 4 and Table 6) and feed small livestock watering tanks. Slightly larger spring and seep areas were identified along the lower reaches of Coon Creek and on Little Sheep Creek and support perennial flow on these lower stream reaches.

2.3.1 Spring Flow Rates and Water Quality

Observed flow rates at the springs ranged from less than 1 gallon per minute (gpm) to over 100 gpm. Flow rates measured at baseline spring monitoring sites are summarized in Table 6.

TABLE 6. SUMMARY OF BASELINE SPRING FLOW DATA

Sta. Name	Flow Rate (gpm)			Sta. Name	Flow Rate (gpm)		
	min	max	avg		min	max	avg
SP-1	1.4	65	22	DS-1	<0.5	35	12
SP-2	2.2	9.4	6.9	DS-2	<0.5	12	4.7
SP-3	0.6	5.4	2.8	DS-3	4.9	117	38
SP-4	5.4	27	13	DS-4	2.2	20	8.7
SP-6	0.9	3.0	1.8	DS-5	<1	18	6.7
SP-7	9.4	112	38	DS-6	<0.5	18	7.3
SP-8	8.1	8.1	8.1				
SP-9	5.4	15	9.4				
SP-10	3.6	8.1	5.8				

Water samples have been collected at five of the primary spring sites (SP-1, SP-2, SP-3, SP-4, and SP-6) that surround the proposed exploration decline area. These springs generally exhibit neutral to slightly alkaline pHs (6.20-8.21) with moderate to high alkalinities (50-240 mg/L). Background nitrate concentrations are low (<0.1 - 0.68 mg/L) at all of the spring sites. Metals concentrations are within regulatory limits; however, manganese at springs SP-1 and SP-2 slightly exceeds the recommended secondary standard for drinking water of 0.05 mg/L, and iron at SP-3 exceeds the recommended secondary drinking water standard of 0.3 mg/L. SP-3 also exhibits slightly higher concentrations of some dissolved metals (Al, Cu, and Cr), but all are well below regulatory standards. Other samples from springs originating from gossan sites show similar water quality to the spring samples with no major differences in dissolved metals concentrations.

3.0 AQUIFER CHARACTERIZATION INVESTIGATIONS

A series of aquifer tests were conducted at the site that include both slug tests and short-term and long-term pumping tests to characterize the hydrogeologic characteristics of the principal stratigraphic units and the fault systems that bound the ore bodies. Each of the tests are described briefly below and references are provided for previous reports containing more detailed information on the individual tests. Table 7 summarizes salient information for each test and the estimated aquifer characteristics derived from test results. Aquifer test analyses are included in Appendix D.

Preliminary Testing

An initial aquifer test was completed for the project that used open PQ and HQ core holes (core diameters of 85 and 63.5 millimeters, respectively) to conduct preliminary tests (Tetra Tech, 2011). The test was designed to provide, for planning purposes, a very rough estimate of water volumes that might be expected during development of the ore deposit. The values obtained from this suggest, as a preliminary estimate, that water volumes as large as 400 to 600 (gpm) might be expected to be produced from the mined deposit zone during production, but are inconclusive due to the limited quality of the holes for this testing purpose.

PW-1 and PW-2 Aquifer Test

A more rigorous aquifer testing program was conducted in November 2011 to refine the earlier estimate of potential flow rates that could be encountered during mining based on the initial exploration/exploration decline (2011 decline) location which was to the north of the current proposed decline site (Hydrometrics, 2012a). Wells PW-1 and PW-2 were installed as pumping wells for the aquifer test. PW-1 was completed in shallow (YNL-0) dolomitic shale bedrock and PW-2 in the upper sulfide zone.

Datalogger/transducers were used to monitoring water levels in PW-1, PW-2, MW-3, and two exploration boreholes SC11-032 and SC11-044. Flow was also monitored near SP-6 in a small tributary drainage to Coon Creek, which is referred to informally by Tintina as Dry Creek. An 8-hour pumping test was conducted at PW-1 at a discharge rate of 1.5 gpm and a separate 5-day test was conducted at PW-2 at a discharge rate of approximately 5 gpm.

The analysis of drawdown data from the test yielded hydraulic conductivity estimates for the shallow (YNL-0) bedrock at PW-1 of approximately 0.03 to 0.6 ft/day (Appendix D). The fractured rock solutions produced the best fit to observed drawdown trends and yielded the lower range estimates. The PW-2 test yielded estimates of hydraulic conductivity for the upper sulfide zone of 0.06 to 0.3 ft/day. No change in surface flow was evident in Dry Creek during either test.

PW-3 and PW-4 Aquifer Tests

A more recent pumping test investigation was conducted in May 2012 to establish aquifer characteristics and revise estimates of potential inflow to the exploration decline based on a revised decline design (Hydrometrics, 2012c). Two new wells were installed as pumping wells for this investigation (PW-3 and PW-4). In addition, two existing exploration holes SC12-116 and SC12-117 were used as observation wells. Forty-eight hour pumping tests were conducted at test wells PW-3 and PW-4 to establish aquifer characteristics for the bedrock units that would be encountered along the path of the proposed exploration decline.

Aquifer test results were analyzed using AQTESOLV (v.4.01) to calculate aquifer transmissivities, hydraulic conductivities, and storage coefficients. Analyses were conducted using solutions for confined aquifers, leaky confined aquifers, and for fractured rock systems. Drawdown results from the PW-3 pumping test for both PW-3 and SC12-116 yielded similar hydraulic conductivity estimates with hydraulic conductivity values for the shallow bedrock unit (YNL-A) ranging from 1.1 to 2.2 feet/day. The analysis of PW-4 drawdown yielded hydraulic conductivity estimates for the USZ of approximately 0.01 to 0.02 ft/day (Appendix D).

PW-5 Aquifer Test

PW-5 was completed in the VVF near its intersection with the UCZ (Figure 3) to help define the hydrologic characteristics of the fault. The well was completed to a depth of 550 feet and penetrates approximately 50 feet into a zone of fault gouge and fractured rock. Exploration boreholes show similar fault gouge material in cores taken through the VVF.

The aquifer test at PW-5 was conducted in January 2015. It was scheduled to be conducted for 72 hours; however, water levels dropped to within a few feet of the pump intake during the step test at the initial flow rate of only 1 gpm. Conducting the aquifer test at a lower rate was not feasible as a lower pumping rate would not adequately cool the pump motor and risk damaging the pump. Therefore, the drawdown data from the 1 gpm initial test was used to evaluate aquifer characteristics.

The water level drew down from 503 feet at the start of the test to 530 feet (within 5 feet of pump intake) after pumping for approximately 20 minutes. Water level recovery was recorded for approximately 17 minutes after the pump was shut off. There was an initial recovery response that was relatively rapid and then water levels essentially stabilized 8 feet lower than pre-test levels. Water quality samples were not collected from PW-5 as there was insufficient time to collect the sample due to the rapid decline in water levels.

The test results were not definitive as the quantity of water pumped during the test could be accounted for almost entirely by the change in well volume. After an initial recovery response, the calculated rate of inflow to the well was less than 0.01 gal/min. This is consistent with the slow recovery observed after drilling this well. Hydraulic conductivity estimates from the PW-5 aquifer test using solutions that account for well storage ranged from 0.02 to 0.09 ft/day (Hydrometrics, 2015). Although these estimates are one to two orders of magnitude lower than the higher estimated permeability of the USZ and two to three orders of magnitude lower than the YNL-A permeability estimates, they may not accurately characterize the permeability of the VVF since the aquifer response was effectively overshadowed by the well storage effects.

VVF Permeameter Testing

To further assess the permeability of the volcano valley fault, five soil samples of the gouge material within the fault zone were taken from three separate exploration cores and submitted to Pioneer Technical Service's for hydraulic conductivity analysis using a Flexible Wall Permeameter test (ASTM Method D5084). The results, shown in Table 8, indicate that the fault gouge present within the Volcano Valley Fault has a very low permeability with hydraulic conductivities ranging from 7.1×10^{-4} to 1.5×10^{-5} ft/day and an average of 2.8×10^{-5} ft/day.

TABLE 8. FLEX WALL PERMEABILITY TEST RESULTS FOR VOLCANO VALLEY FAULT SOIL SAMPLES

Lab No.	Sample No.	Confining Pressure (psi)	Hydraulic Conductivity (ft/day)	Hydraulic Conductivity (cm/sec)
G15247 SC11	SC-11-008	34.6	2.8×10^{-5}	1.0×10^{-8}
G15248 SC11	SC-11-036	37.2	2.3×10^{-5}	8.1×10^{-9}
G15249 SC12	SC-12-129	42.0	1.5×10^{-5}	5.4×10^{-9}
G15250 SC14	SC-14-164	50.0	6.0×10^{-5}	2.1×10^{-8}
G15251 SC14	SC-14-170	41.3	7.1×10^{-4}	2.5×10^{-7}

PW-6 Aquifer Test

The PW-6 borehole was drilled to a total depth of 1,234 feet bgs and completed within the Buttress Fault Zone. An aquifer test was conducted on PW-6 in October 2014 at a discharge rate of 6 gpm. The pumping phase of the test was shut down after approximately 100 minutes and produced a drawdown of approximately 275 feet. Water levels were recorded during the pumping and recovery phases of the aquifer test.

The drawdown curve for this test shows a linear drawdown trend typical of a low yield well where well bore storage is a high percentage of the water being discharged. Analyses were performed using several analytical solutions that correct for well bore storage effects including Papadopoulos-Cooper (1967) for confined aquifers, and two dual porosity solution for fractured rock systems (Moench, 1984 and Barker, 1988). This recovery solution was

also used to estimate transmissivities as the recovery data for single well tests is typically more reliable. Estimates of hydraulic conductivity at well PW-6 (completed in the Buttress Fault) ranged between 0.004 ft/day and 0.06 ft/day (Appendix D).

PW-6N Air Test

Well PW-6 was modified/deepened in the spring of 2015 to evaluate the hydrologic characteristics of the underlying Neihart quartzite; the new well is called PW-6N. Well PW-6N was completed with an open borehole below the cemented screen of PW-6, and extends into supplemental fractures in the Neihart Formation associated with the Buttress fault. Air lift testing after taking the borehole to depth produced very high flows; estimated at 500 plus gallons per minute. No additional testing was conducted on PW-6N; however, the data indicate there are high permeability fractures within the Neihart quartzite adjacent to the Buttress Fault.

PW-7 Slug Test/Short-Term Aquifer Test

Well PW-7 is located within the Sheep Creek drainage; the borehole was drilled to a depth of 1,350 feet bgs and completed in the lower ore zone. A slug test rather than a pumping test was conducted on PW-7 due to the low yield of the well, and the fact that the well is closed off at the surface due to artesian conditions (static water level was approximately 12 feet above the ground surface). A rising head slug test was conducted on October 2014. The well was instrumented with a pressure gauge and a pressure transducer. Water was released to reduce pressure at the wellhead to zero and then the well was shut in and allowed to recover. Two separate tests were conducted.

The water level was displaced approximately 8 feet during the PW-7 slug tests. Water levels recovered slowly after closing the spigot, taking approximately 135 minutes to stabilize to within 0.5 inches of the pre-test water level. The PW-7 slug tests were analyzed using analytical solutions for confined and unconfined porous media aquifers and for a dual porosity fractured aquifer. The analyses produced hydraulic conductivities ranging from 0.2 ft/day to 0.1 ft/day (Appendix D). These estimated hydraulic conductivities are similar to results from the other Newland Formation wells. However, they are not consistent with the

recovery of the well after well completion; which took more than 30 days to recover to the static condition.

In addition to the slug test, drawdown was measured during water quality monitoring at PW-7 during the March 2015 monitoring event to provide additional data on the aquifer characteristics of the LCZ. The well was purged for approximately 39 minutes at 1-1.5 gpm prior to shutting down the pump; the drawdown in the well was measured at approximately 36 feet. The drawdown curve did not stabilize during well purging. Water levels did not recover to pre-pumping conditions 14 days after the well was sampled. The PW-7 short-term aquifer tests were analyzed using analytical solutions for fracture bedrock and recovery/residual drawdown analyses. Hydraulic conductivity estimates from the PW-7 aquifer tests ranged from 0.001 ft/day to 0.0003 ft/day. Although the drawdown data from the well sampling is limited in duration, the lower hydraulic conductivity estimates from this test appear to be more representative of the slow water level recovery that was observed after well completion and during well sampling.

PW-8 Aquifer Test

A long-term (31-day) aquifer test was conducted on PW-8 in July and August 2014. Well PW-8 is completed in YNL-A shale just above the contact with the Upper Sulfide Zone (USZ). In addition to characterizing the permeability of the USZ unit, the purpose of the extended test was to assess the extent to which extended pumping would affect water levels in overlying units and at nearby surface water sites. Additional monitoring sites were setup prior to conducting the aquifer test. Three temporary piezometers were installed in the Coon Creek (PZ-12), Sheep Creek (PZ-11), and Dry Creek (PZ-10) alluvial systems (Figure 3). Three surface water sites were also monitored during the PW-8 aquifer test: SW-3 on Coon Creek upgradient of the hay meadow, SW-14-1 on Coon Creek in the hay meadow, and SW-14-2 on Dry Creek directly south of PW-8 (Figure 2). Sites SW-14-1 and SW-14-2 are temporary sites that were established for the aquifer test monitoring program.

Datalogger transducers were installed at 11 observation sites to collect background water levels for 28 days prior to the start of the PW-8 aquifer test. A step test was conducted on

PW-8 on August 7, 2014. The flow rates for the step test were approximately 2.2 gpm, 5.0 gpm, and 10 gpm. The well showed a steep decline in water levels during the final step, indicating the well might not be capable of sustaining flow at 10 gpm.

A 31-day pumping test was conducted at PW-8 from August 8 to September 8, 2014. Water levels were monitored using datalogger transducers at 11 observation sites. Manual water levels were collected at more distant observation sites. The PW-8 aquifer test was started on August 8 at a discharge rate of 5.5 gpm. The discharge rate was increased to approximately 8 gpm on August 11, 2014 as water levels had stabilized at the lower discharge rates. The discharge rate was increased again on August 14, 2014 to 10 gpm to maximize the drawdown within the pumping well and observation wells. The discharge remained at this rate for the remaining 24 days of the test with the exception of a short-term shut down of the well due to a power outage. A power outage occurred at approximately 1:15 on the morning of August 23, 2014, which resulted in the pump being shut down for approximately seven hours before power and pumping could be reestablished. The PW-8 aquifer test was shut down on September 8, after 31 days of pumping.

Wells that exhibited measureable drawdown during the PW-8 aquifer test include pumping well PW-8 and observation wells PW-4, PW-3, and MW-1B (Figure 3). The maximum drawdown at PW-8 was approximately 44 feet. Well PW-4, located 23 feet to the northeast, had a maximum drawdown of 6.5 feet. A maximum drawdown of approximately 2.4 feet was observed at PW-3, which is located 709 feet south of PW-8. Piezometer PZ-10, which is completed in the shallow groundwater system associated with Coon Creek, did not have any measureable drawdown from the PW-8 aquifer test. This suggests that Coon Creek and the shallow groundwater associated with Coon Creek are not directly connected to the deeper groundwater system in the vicinity of the USZ. The remaining observation sites including all piezometers in the shallow aquifer systems associated with Sheep Creek, Coon Creek, and Dry Creek did not show any measureable drawdown from the PW-8 aquifer test. Water levels in all of the wells that exhibited drawdown recovered slightly during the power outage on August 23. With the exception of Well MW-1B, drawdown returned to the same level shortly after the pump was restarted.

Pumping well PW-8 recovered to pre-test levels within two days of shutting down the pump. Water levels recovered 1.4 feet above pretest levels in PW-8. Observation wells PW-4 and PW-3 recovered to within pretest levels in 2.5 days and 3 days, respectively; with water levels in both wells recovering above (1.0 and 0.7 feet, respectively) the pretest levels.

Curve-matching graphs for the wells that had measureable drawdown during the PW-8 and PW-9 aquifer tests are included in Appendix D. The drawdown curves from the PW-8 pumping test indicate that wells PW-8 and PW-3 (both of which are completed in YNL-A) yielded similar permeabilities. Estimated hydraulic conductivity values range from 4.6 to 5.8 ft/day based on the observed drawdown trend at PW-3 during the PW-8 pumping test, and from 1.0 to 2.3 ft/day at the PW-8 pumping well. The PW-3 hydraulic conductivity estimate from the PW-8 test is slightly higher than estimates from the two previous tests conducted on PW-3 in 2011 and 2012, which yielded hydraulic conductivity values of 1.1 to 2.1 ft/day (Table 8). The calculated hydraulic conductivities assume a 50-foot aquifer thickness, which is equal to the thickness of the gravel pack in PW-8. A wide range of storativity estimates (1×10^{-4} to 8×10^{-6}) were derived from the PW-3 drawdown curve. The storativity value from the Theis solution may be overestimated since the drawdown curve is not similar to a typical Theis curve.

PW-9 Aquifer Test

A step test was conducted at PW-9 on September 17, 2014 with discharge rates of approximately 3, 6, and 9 gpm. The discharge rates for each step were sustained for 80 minutes. A long-term aquifer test at PW-9 was conducted for 19 days from September 25 to October 14. The discharge rate for the PW-9 aquifer test was maintained at 5 gpm from September 25, 2014 to October 8, 2014 at which point the discharge rate was increased to 6 gpm in an attempt to maximize the drawdown in the pumping well and observations sites without dewatering the well. The 6 gpm discharge rate was maintained for six days until the pumping test was shut down on October 14, 2014 as drawdown had stabilized in the pumping well and observation wells.

Water levels were monitored during drawdown and recovery phases of the test using datalogger transducers at 11 observation sites. In addition, manual water levels were collected at more distant observation sites. Flow and stage measurements were collected at three surface water sites (SW-14-1, SW-14-2, and SW-3) and one spring (SP-06).

Only four wells exhibited drawdown during the PW-9 pumping test: PW-9, PW-10, MW-3, and MW-9 (Figure 3). Wells PW-9 and MW-3 are completed in the USZ, whereas wells MW-9 and PW-10 are completed above and below the USZ, respectively. The maximum drawdown at well PW-9 was 62.7 feet at the end of the pumping test. Well MW-3, located approximately 380 feet to the west of PW-9, had the largest drawdown (12.4 feet) of the observation wells. Although well PW-10 and MW-9 are located within 16 to 21 feet of PW-9 laterally, the maximum drawdown was much less (7.6 feet and 8.7 feet, respectively) than at MW-3. Well MW-3 is completed in the same hydrostratigraphic unit as PW-9 and could be considered to be fairly well connected to PW-9. The subdued drawdown in nearby well PW-10, completed below the USZ, and MW-9, completed above the USZ, suggests the hydrostratigraphic units above and below the USZ are only partially or poorly connected to the USZ and UCZ subunit. Drawdown was not observed in the more distal observation wells monitored during the PW-9 aquifer test. The analysis of the drawdown curves for PW-9 and MW-3 yielded hydraulic conductivity estimates of 0.2 to 0.7 ft/day and 0.4 to 1.0 ft/day, respectively (Appendix D). Storativity estimates from well MW-3 ranged from 6.0×10^{-5} to 9.0×10^{-5} .

Weekly surface water flow and/or stage monitoring was conducted at three surface water sites (SW-3, SW-14-1, and SW-14-2) and in piezometers completed in the shallow alluvial systems during both the PW-8 and PW-9 aquifer tests. The surface water sites and piezometers showed no influence from extended pumping of the bedrock aquifer at the proposed development depths.

PW-10 Aquifer Test

Aquifer characteristics were evaluated at PW-10 by monitoring water level drawdown during well purging for water quality sampling. The water level in PW-10 drew down

approximately 34 feet after pumping for 26 minutes. Water levels recovered within 0.01 feet approximately 20 minutes after cessation of well purging. Analytical methods were used to estimate hydraulic conductivity of the YNL-B below the UCZ/USZ; these ranged between 0.001 ft/day and 0.007 ft/day, which is in the lower range of results from well completed in the Newland Shale above the Volcano Valley Fault.

In addition to the aquifer tests described above, slug tests were also performed on monitoring wells MW-4A and MW-4B following well completion and development. Slug tests at MW-4A, completed in the Sheep Creek alluvium, produced oscillatory fluctuations in water levels during testing due to the inertial effects from an extremely rapid recovery response. This type of response is common in high permeability aquifers and was analyzed using an analytical solution developed by Springer and Gelhar (1991) that extends the Bouwer-Rice (1976) solution for a slug test in a homogeneous, anisotropic unconfined aquifer to include inertial effects in the test well. The solution yielded an estimated hydraulic conductivity for the Sheep Creek alluvial aquifer on the order of 200 feet per day.

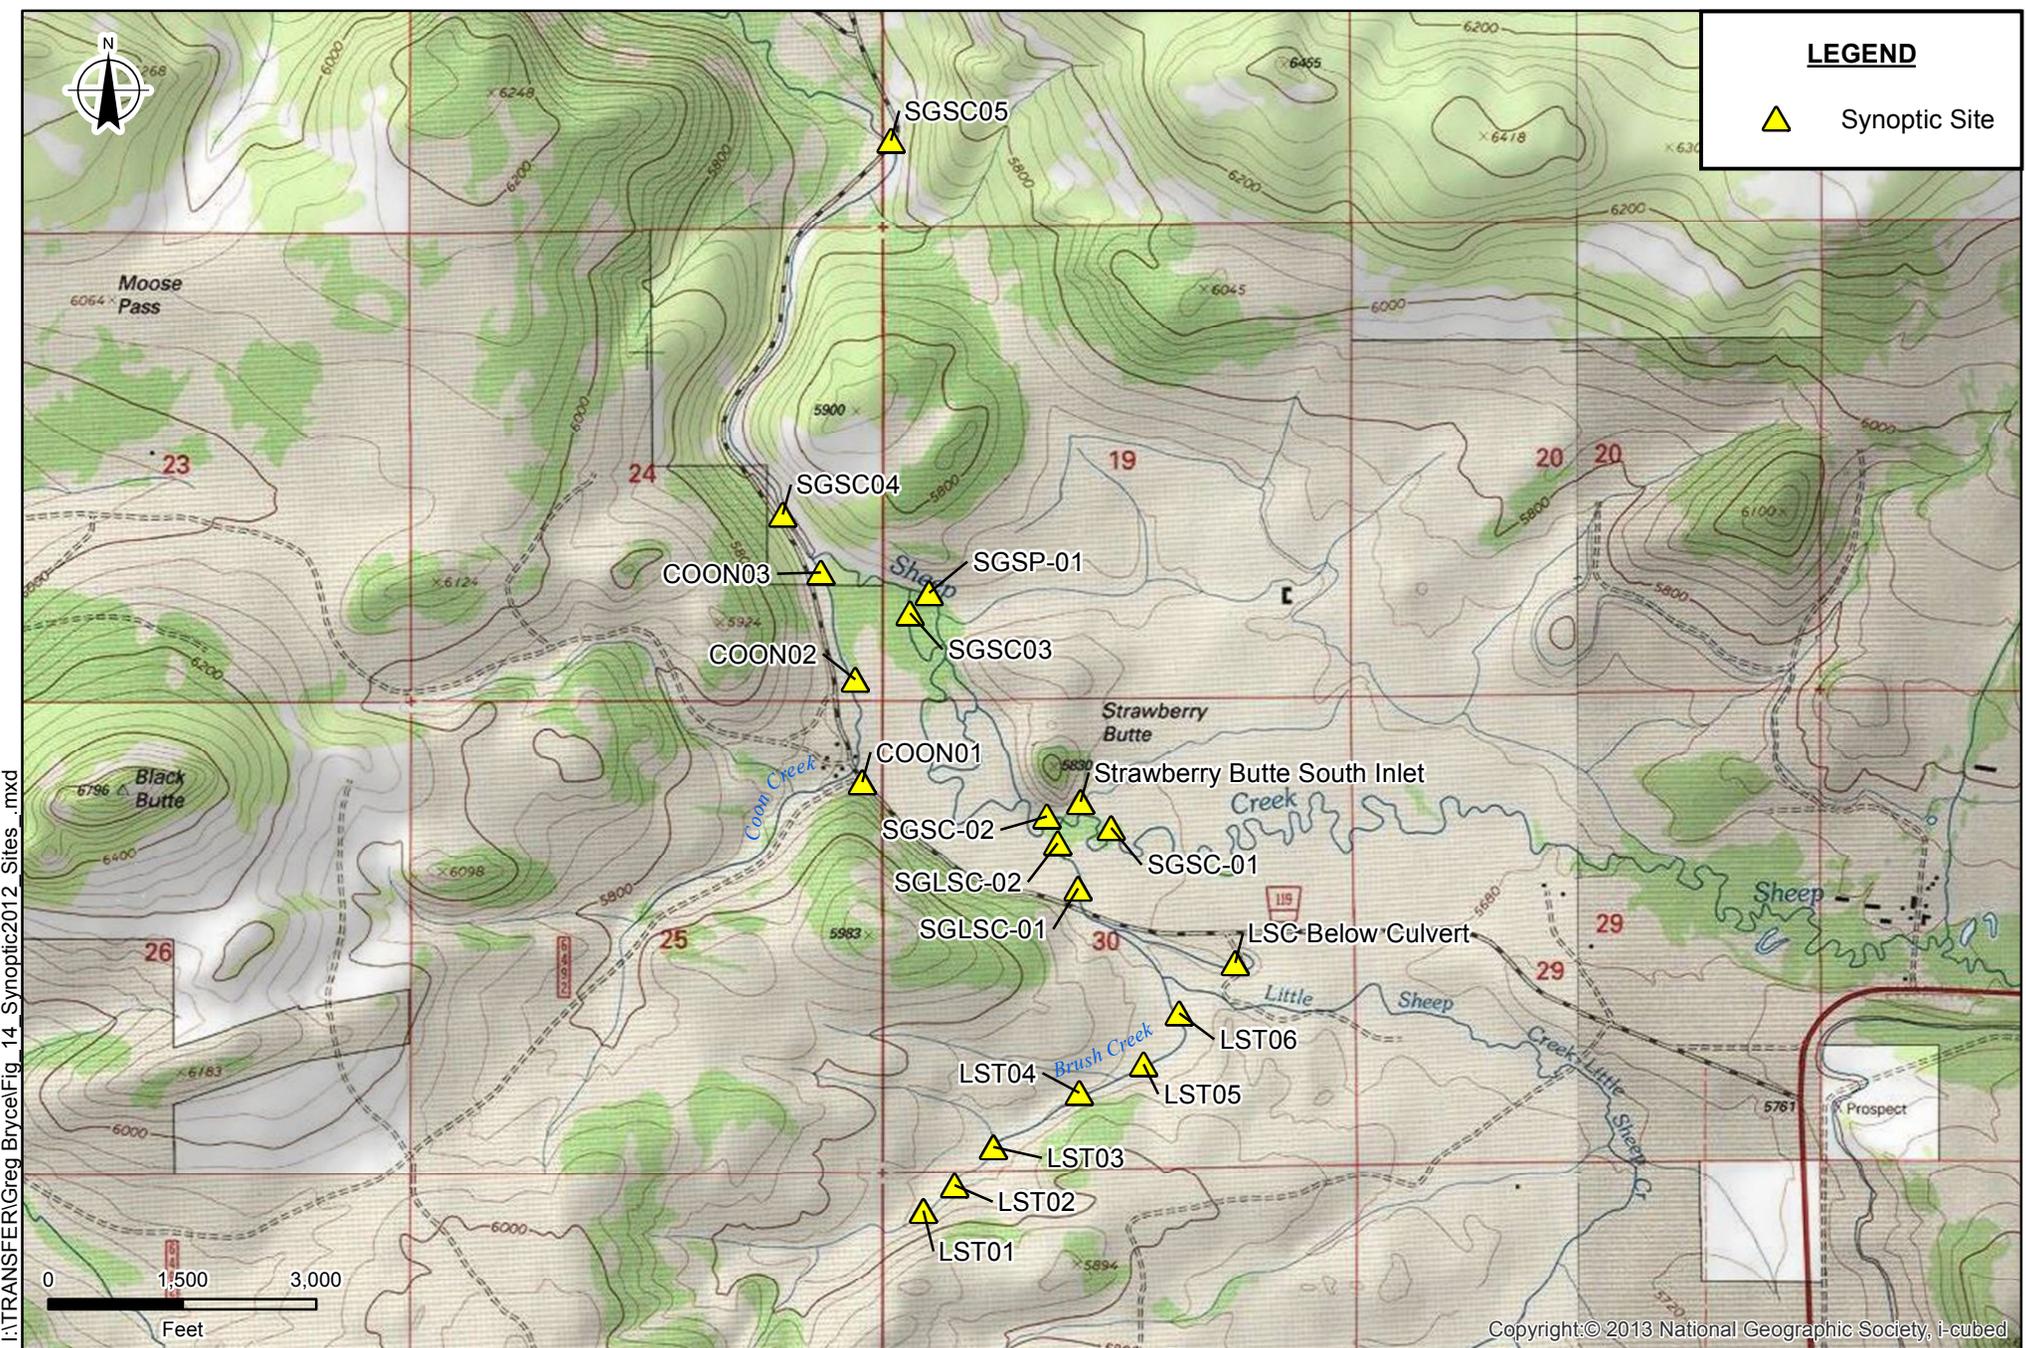

Slug testing at MW-4B, which is completed in the shallow YNL-A bedrock, produced a more conventional response that was analyzed using solutions developed by Bouwer and Rice (1976) and Hvorslev (1951) and yielded an estimated hydraulic conductivity of 7 feet per day for the shallow bedrock.

4.0 GROUNDWATER SURFACE WATER INTERACTIONS

4.1 SHEEP CREEK

Potentiometric data indicate that Sheep Creek is hydrologically connected with the alluvial aquifer in the Sheep Creek Valley. Surface water monitoring data show a general increase in flow from upstream monitoring sites (USGS-SC1 and SW-2) to downstream (SW-1); however, the majority of that increase appears to be attributable to tributary inflow. An initial synoptic survey was conducted in August 2012 to characterize inflows to Sheep Creek, in the project area. The location of the synoptic survey sites are shown in Figure 14. The large decreases and increases in flow are inconsistent with hydrologic conditions in this area. The synoptic results showed over 6 cfs of streamflow loss between SGSC-01 and SGSC-04 and approximately 2 cfs of increase through the canyon (Table 9). Flows would typically be expected to increase in surface systems as alluvial systems are pinched out where streams enters narrow canyons and potentiometric data in the Sheep Creek alluvial system appear to lend support to the concept that Sheep Creek is receiving groundwater recharge in this area. The atypical trends shown in the August synoptic survey may have been related to irrigation effects. The synoptic survey was conducted shortly after irrigation was discontinued in the hay meadow. The cessation of flood irrigation in the hay meadow represents a large stress to the hydrologic system and there may not have been sufficient time for the systems to re-equilibrate.

A second survey was conducted in October 2012 to further evaluate the groundwater/surface water interaction on Sheep Creek and two small drainages (Coon Creek and Brush Creek) adjacent to the project area. The results of the October 2012 survey are tabulated in Table 10. The October 2012 synoptic survey on Sheep Creek included additional monitoring sites on Sheep Creek to provide supplemental data to evaluate the changes seen in the August 2012 survey. During this second synoptic survey changes in discharge on Sheep Creek were generally within the measurement error (10-15%) throughout the survey area. The only exception was at SGSC-03 below little Sheep Creek, where the measured flow was almost 4 cfs lower than would be expected based on the flow in Sheep Creek combined with the

LST-04	--	0.1	--	
LST-05	--	0.1	--	
LST-06	--	0.16	--	Most downstream site on Brush Creek
Coon Creek Survey				
Coon-01	--	0.1	--	Coon Creek just as it enters the hay meadow, SW-3
Coon-02	--	0.22	--	Coon Creek mid-point in the hay meadow
Coon-03	--	0.19	--	Coon Creek immediately upstream of Sheep Creek confluence
Sheep Creek Survey				
2SGSC-01	21.5	--	--	Most upstream site in hay meadow
SGSC-02	22.2	--	--	Sheep Creek upstream of Little Sheep Creek confluence (includes discharge from un-named tributary south of Strawberry Butte)
SGLSC-02	--	1.12	23.32	Little Sheep Creek before Sheep Creek confluence
SGSC-03	19.51	--	--	Sheep Creek upstream of Spring Creek confluence
SGSP-01	--	0.44	--	Spring Creek before Sheep Creek confluence
Coon-03	--	0.19	20.14	Coon Creek upstream of Sheep Creek confluence
SGSC-04	20.57	--	--	Sheep Creek downstream of Coon Creek confluence in canyon north of hay meadow
SGSC-05	19.05	--	--	Sheep Creek at quarterly monitoring site SW-1

measured inflow from Little Sheep Creek. This magnitude of change cannot easily be accounted for by stream flow loss near the SGSC-03 measurement site, however, this gaging site is in a location where Sheep Creek is highly braided and the channel is not ideal for obtaining an accurate discharge measurement. The confidence level of the data from this station is therefore low. With this exception, changes in stream flow in Sheep Creek during the October 2012 synoptic survey appear to be largely accounted for by tributary inflows. Groundwater inflow to Sheep Creek within the Project area was not measurable in the 2012 synoptic survey and indicates that groundwater contributions to the stream account for less than 10 to 15% of the total flow rate on this stream reach.

A simple Darcy's flux calculation was used to confirm that the estimated flux from the Sheep Creek alluvial groundwater system to Sheep Creek in this lower reach is consistent with the small fluctuations shown in the synoptic results. Darcy's Law can be used to estimate flow rate given a hydraulic conductivity (K), hydraulic gradient (I) and flow cross sectional area (A) where:

$$\text{Discharge (Q)} = K \times I \times A$$

Given an assumed thickness of the Sheep Creek alluvium of 16 feet as observed at MW-4A, and an assumed maximum width of 1,500 feet, an average hydraulic gradient (I) of groundwater of 0.008 and an average hydraulic conductivity (K) of 200 feet/day, Darcy's Law yields a groundwater flux estimate of 200 gpm (0.44 cfs) flowing through the alluvium towards Sheep Creek within the immediate project area. If all of this discharged to Sheep Creek, it would be equivalent to just over 2% of the baseflow observed in Sheep Creek during the synoptic survey. This confirms that groundwater inputs to Sheep Creek within this reach are too small to physically quantify using open channel flow measurement techniques.

4.2 BRUSH CREEK AND COON CREEK

The synoptic survey on Brush Creek indicates discharge of shallow groundwater at the head of this draw and then no measureable change in flow between sites LST-02 and LST-05

(Figure 14). There was a small increase (0.06 cfs) between LST-05 and LST-06 as Brush Creek approaches the Little Sheep Creek alluvial system. Water quality data were used to further assess groundwater and surface water interactions on Brush Creek in the 2013 investigation, and that evaluation found that the water quality in Brush Creek was not indicative of groundwater from the shallow bedrock groundwater system in the vicinity of the proposed underground LAD area (Hydrometrics, 2013a). The source of the small increase in flow below LST-05 is unknown but may be associated with the Little Sheep Creek alluvial system.

A synoptic survey was conducted on the lower reach of Coon Creek where it enters the Sheep Creek alluvial system to its confluence with Sheep Creek. The discharge in Coon Creek at the most upstream site (COON-01) was approximately 0.1 cfs. Coon Creek discharge approximately doubled between sites COON-01 and COON-02; the discharge remained near 0.2 cfs until its confluence with Sheep Creek (Table 10). Data from the drilling at PW-3 and the PW-8 pumping test and water level elevation data provide evidence that Coon Creek above SW-3 is not in direct connection with the deeper bedrock groundwater system.

WELL LOGS

MONITORING WELL LITHOLOGIC AND COMPLETION LOG

JOB NO: 114-710301.300 WELL NO: MW-1A

PROJECT: Sheep Creek STATE: MT COUNTY: Meagher LOGGED BY: J Maus

LEGAL LOCATION: T 12N R 6E S 24 TRACT DDD DESCRIPTIVE LOCATION: Approximately 1000 ft N of County Rd 119 Intersection w/ Butte Creek Rd on west side of County Rd 119.

DATE STARTED: 6/29/2011 DATE COMPLETED: 6/29/2011 DRILLING CO/ DRILLER: O'Keefe - Larry Gagnon

DRILLING METHOD: Air Rotary BOREHOLE DIAM (IN): 6" DRILL FLUIDS USED: None

TOTAL DEPTH DRILLED: 38 TOTAL DEPTH CASSED: 34 INTERVAL PERFORATED FROM OR SCREENED (FT.): 25/34 DIAMETER: 2" CASING TYP: PVC

METHOD OF PERFORATION: Open Hole, Open Bottom, Saw Slotted, XX Factory 0.020 (size), Other. DURING WELL CONSTRUCTION WAS/WERE: Well Developed, Well Pumped, Water Samples Collected, Material Samples Collected. YES/NO table with X marks.

ANNULAR COMPLETION CHARACTERISTICS: WELL PROTECTOR: LENGTH: 5ft, DIAM: 6". SURFACE SEAL TYPE: Cement, Sand. BACKFILL MATERIAL: Bentonite. FILTER PACK TYPE: 10/20 Sand. FROM/TO table.

STATIC WATER LEVEL: 0 ft TPVC DATE: 6/30/2011 MEASURING POINT DESCRIPTION/ ELEVATION: TPVCN MEASURING POINT RELATIVE TO GROUND SURFACE (+/-) +2.0

REMARKS: Well just barely flowing out top of 2" pvc

Table with 3 columns: INTERVAL(FT), LITHOLOGIC DESCRIPTION, REMARKS. Includes rows for intervals 0-20, 20-24, 24-30, 30-32, 32-38 and detailed lithologic descriptions.

GRAPHICS

GEOLOGICAL DESCRIPTION

0.0 - 10.0' **Clayey Sand**
 Brown/Orange poorly sorted fine to coarse sand with 20% clay and trace gravel.

10.0 - 68.0' **Siltstone**
 Orange/Red/Tan highly weathered siltstone. Start making water at 55 feet (10-15 gpm)

68.0 - 80.0' **Shale**
 Dark gray/black soft shale with clay

80.0 - 100.0' **Shale**
 Dark gray/black soft shale with clay, with minor hard gray layers

100.0 - 200.0' **Shale**
 Black to dark gray silick shale, hard drilling with minor weathering/fractures at 140 to 150'. Increasing water with depth: ~1 gpm 100-175', 5 gpm @ 175', 10 gpm @ 200'

200.0 - 260.0' **Shale**
 Black to dark gray silick shale with traces of very fine pyrite. Increasing water with depth: 20 gpm @ 205', 35 gpm @ 210'

260.0 - 285.0' **Shale with massive Sulfide**
 Dark gray/black shale and equal parts pyrite; pyrite sheen on water. Making 50 gpm at 285'

285.0 - 305.0' **Massive Sulfide with shale**
 Coarse pyrite (3/8") with 30% shale; 2-5% calcite chips. No increase in water.

GEOLOGICAL DESCRIPTION

0.0 - 1.0' **TOPSOIL**
Brown Top Soil.

1.0 - 25.0' **SANDY CLAYEY GRAVEL**
Brown sandy clayey gravel. Gravel is fine to medium subrounded to angular. Fewer fines at 20'. Wet at 5'.

25.0 - 27.0' **CLAYEY GRAVEL**
Sharp transition to orange/ brown clayey gravel.

27.0 - 55.0' **SHALE**
Contact with dark grey shale (bedrock) no evidence of sulfide. At 40' hole is producing <.5 gpm water.

55.0 - 59.0' **SHALE**
Dark grey shale with thin interval of brown shale. Increased flow. Producing ~6 gpm of discharge.

SAMPLE NOTES

GRAPHICS

GEOLOGICAL DESCRIPTION

0.0 - 2.0' **Topsoil**
Dark brown, soil transitioning to shale with depth, dry.

2.0 - 20.0' **Shale**
Blue grey, dolomitic shale, small fracture located at 11 feet with no water associated, dry.

20.0 - 35.0' **Weathered Shale**
Tan, reddish brown, weathered/altered shale. Dry

35.0 - 55.0' **Granodiorite**
Grey, reddish orange weathered granodiorite. making water at 45 feet (0.5 gpm).

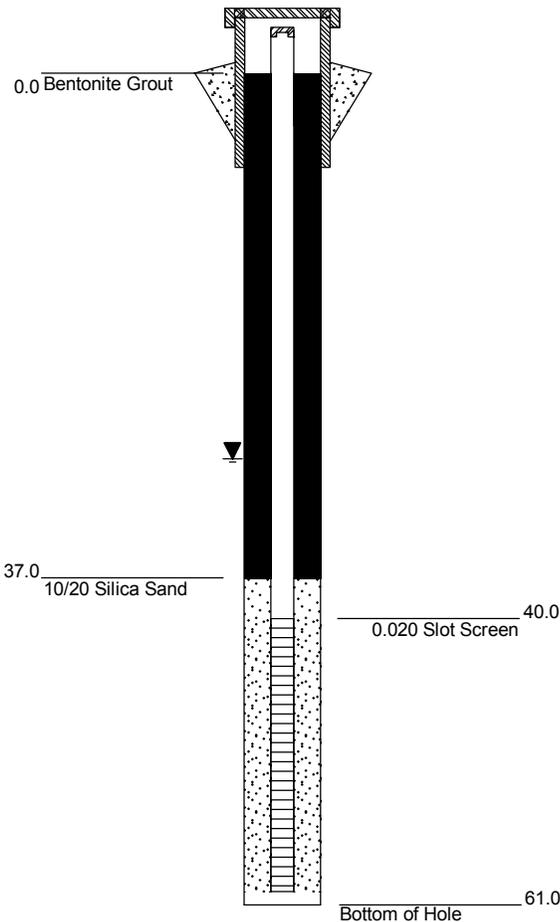

55.0 - 70.0' **Granodiorite**
Dark grey, highly competent granodiorite. No increase in flow.

WELL CONSTRUCTION

GRAPHICS

GEOLOGICAL DESCRIPTION

0.0 - 1.0' **TOPSOIL**
 Dark brown, sand and silt topsoil with angular-subrounded clasts weathered shale clasts. Dry.

1.0 - 15.0' **SILTY SOIL**
 Buff tan colored silt with moderately weathered shale clasts. Shale is orange-tan to brown, mottled black to tan, very thin laminated with very thin black veins and dendrites (pyrite?), shale is weathered along veins. Clasts have iron oxide fractured surfaces with black dendritics, reacts with HCl. Dry.

15.0 - 20.0' **SILT/SHALE**
 Gray brown silt with angular weak to moderately weathered shale clasts; dark gray to buff tan with iron oxidized fracture surfaces, weak to moderate reaction to HCl. Dry.

20.0 - 25.0' **SHALE**
 Thinly bedded, weakly weathered black shale; black to buff-tan. Some iron surfaces and calcite vein fill; up to 4 mm. Alteration is peripheral to fractures only, weak reaction to HCl. Dry.

25.0 - 30.0' **SHALE**
 Thinly bedded dark gray to black shale as above. Weak reaction to HCl.

At 28 feet, less weathering, chips were very angular, small (less than 1/4"), seems to be more competent shale. Dry

30.0 - 40.0' **SHALE**
 Hard black shale, not weathered, occasional iron oxide fracture surfaces, very thin calcite veins.

At 39 - 39.5 feet, weak to moderate weathered black shale; tan-brown to black, includes iron fractured surfaces, very thin calcite veins. Rock mass does not react with HCl. Cuttings returned with fine silt and had silty clay coating.

40.0 - 52.0' **SHALE**
 Non-weathered, thinly bedded black shale with very thin calcite veins. Hard, slower drilling, small, less than 1/4" chip return.

52.0 - 52.5' **SHALE**
 Gray-brown silt with weakly oxidized black shale as above, orange-yellow iron oxide on fracture surfaces.

55.0 - 60.0' **SHALE**
 Thinly bedded black shale with abundant fines, soft drilling, very dusty, thin calcite veins.

At 56 feet, one foot into new rod, entered first water, produced approximately 4 gallons until dry. Wet

60.0 - 68.0' **SHALE**
 Very black thinly laminated black shale, abundant fines - silty calcite veins up to 1 cm, shale is calcareous. Wet to damp.

GRAPHICS

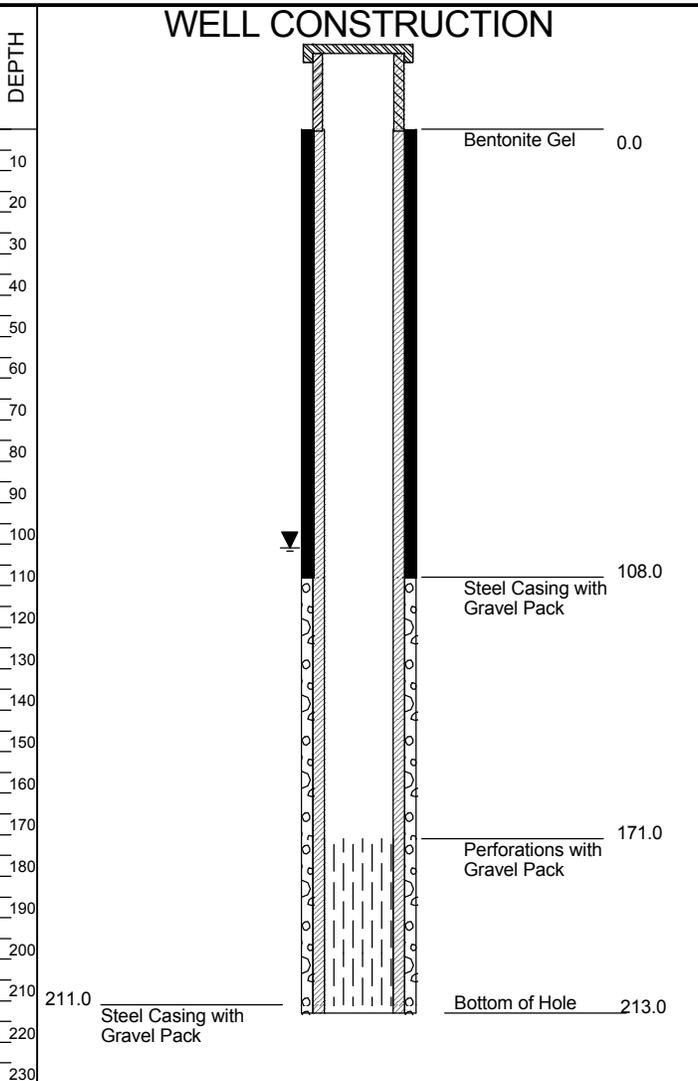

GEOLOGICAL DESCRIPTION

0.0 - 1.0'	TOPSOIL Dark brown, sand and silt topsoil with angular-subrounded weathered shale clasts, dry.
1.0 - 3.0'	SHALE Orange-brown, highly weathered shale and buff tan silt, dry.
3.0 - 5.0'	SHALE Buff tan, weathered shale and silty fines, dusty, occasional red-brown fines, dry.
5.0 - 12.0'	SILT/SHALE Increased red-brown silt with brown-gray oxidized, silty shale, weakly reaction to HCl, dry.
12.0 - 20.0'	SHALE Thinly laminated, weak to moderate oxidation, orange-brown to black shale, with very thin calcite veins, occasional thick calcite vein fill chip, fractured surfaces are weak to moderately oxidized, occasional laminations are red-orange oxidation, dry.
At 17 - 20 feet,	Less weathering, decreased silty fines, more competent shales, approximately 40% of return are chips.
20.0 - 35.0'	SHALE Weakly weathered black shale with tan-gray silty fines, angular to subangular chips, large fragments up to 3/4 inch. Medium gray to black thinly lam shale, fractured surfaces have common red-orange oxidation. Weak reaction to HCl. Dry.
35.0 - 48.0'	SHALE Weak to no weathering, no silty fines, competent shale, slower drilling, fine to coarse angular chips; thinly laminated, dark gray to black, weakly reactive to HCl. Dry.
48.0 - 62.0'	SHALE Fractured shale, abundant black powdery fines, soft drilling. Thinly to thick laminated dark gray to black shale, no oxidation, not reactive to HCl, minor very thin calcite veins. Dry.
62.0 - 70.0'	SHALE Dark gray shale to light gray shale is very thinly to thickly laminated, weak reaction to HCl. Dry. at 64 feet, dusty, abundant silty-powdery fines with coarse chips, possible shear zone.
at 68 feet,	encountered water upon re-entry with additional drilling rod. Wet.
70.0 - 80.0'	SHALE Abundant fines, powdery, very dusty, only approximately 10 to 15% small chips, less than 1 cm, weekly reactive to HCl. Ten feet of water at 80 feet at the time of drilling.

DEPTH (ft)	GRAPHICS	GEOLOGICAL DESCRIPTION
0.0 - 6.0'	[Symbol]	Unconsolidated Sandy Clay Dark gray clay with fine to coarse sand, about 3%.
6.0 - 50.0'	[Symbol]	Unconsolidated Sandy Clay with Fine Gravel Cuttings consist of 10% multilithic, sub-angular rock fragments, sand- to fine gravel-sized, in predominantly red/brown (oxidized) clay 90%. 20.0 - 50.0' Rock fragments include black shale and gray quartz. 30.0 - 50.0' Color becomes tan to brown, cuttings are 75% clay; 25% multilithic, sub-angular to sub-rounded rock fragments, clasts are sand-sized to fine gravel-sized.
50.0 - 118.0'	[Symbol]	Unconsolidated Sandy Gravel Cuttings are 85% multilithic, sub-rounded to sub-angular fine gravel and 15% sub-rounded coarse sand. At 70-90 feet, fragments more angular, with trace fine sand and silt. At 84 feet, borehole is not producing water. 93-95 feet: Granite boulder. Cuttings are 80% multilithic, sub-angular fine gravel, with increasing percentage of shale clasts; 10% sub-angular to sub-rounded, fine to coarse sand; 10% tan clay. Shale clasts effervesce.
118.0 - 130.0'	[Symbol]	Dark Gray Shale interbedded with Siltstone Hard drilling. Cuttings are 95% rock fragments, predominantly shale with gray/tan siltstone; about 5% tan sandy clay. Shale clasts have a trace of fine pyrite crystals and some fine-bladed barite crystals. At 125 feet borehole is making 30gpm.
130.0 - 140.0'	[Symbol]	Black Shale Cuttings are 90% fine black shale rock fragments; 9% sub-angular medium-coarse grained sand; and 1% fine bladed barite crystals.
140.0 - 150.0'	[Symbol]	Dark Gray Shale Cuttings are 85% sub-angular sand-sized to gravel-sized rock fragments, primarily shale, very fine disseminated pyrite (or chalcopyrite?) crystals (within microfractures?); 14% fine to medium-grained multi-lithic sand; about 1% bladed barite crystals. Orange coating (oxidation?) on nearly all shale and sand clasts. At 145 feet borehole is making 15gpm.
150.0 - 240.0'	[Symbol]	Dark Gray Shale interbedded with Siltstone Cuttings are large clasts, dark gray shale and light gray to light tan sandy siltstone; siltstone clasts may contain very fine orange (oxidized?) streaks; many shale clasts effervesce, though not all; trace pyrite crystals, trace barite crystals (bladed, stubby, acicular). 165-205 feet: Borehole is making about 20gpm. 190-200 feet: Quartz sandstone and siltstone in return with shale cuttings. Shale and siltstone cuttings in return are fine- to coarse-sand sized; orange oxidation on a few clasts; trace very fine disseminated pyrite (chalcopyrite?) crystals and barite crystals.

GEOLOGICAL DESCRIPTION

0.0 - 0.5' **Top Soil**
Top Soil

0.5 - 37.0' **Dolomite**
Blue grey, dolomite. slight efferevecense, Dry

37.0 - 42.5' **Shale**
Grey, hard shale with soft zone at 41'

42.5 - 50.0' **Shale**
Grey, hard shale with sulfides (some massive), highly oxidized, moderately weathered. Not making water

50.0 - 92.0' **Shale**
No Returns softer drilling

92.0 - 110.0' **Shale**
Yellow orange, orange chert with minor grey shale. More shale with depth

110.0 - 145.0' **Shale**
grey to dark grey, dolomitic shale with calcite veins.

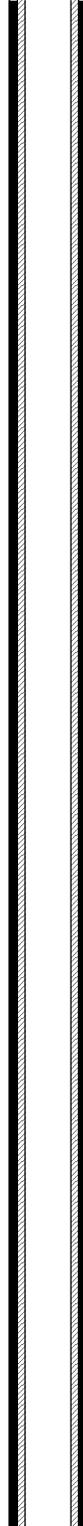

145.0 - 180.0' **Shale**
Dark grey, shale with minor fine grained pyrite. Not making water

180.0 - 270.0' **Shale**
Dark grey shale with fine to coarse grained pyrite. Coarser pyrite with depth, massive pyrite around 268-270'. Making <5 gpm at 260 feet.

270.0 - 385.0' **USZ**
Dark grey silicified shale with massive sulfide. Making 3-5 gpm.

SAMPLE NOTES

GRAPHICS

GEOLOGICAL DESCRIPTION

0.0 - 20.0' **Sandy clay**
 Low oxidized tan clay with 10%-20% angular to sub-angular medium orange sand. 20 gpm at 20'.

20.0 - 60.0' **Siltstone**
 Angular to sub-angular moderately weathered yellow and red siltstones. Moderate oxidation on 40%-50% of facies. 20-30 gpm at 30'.

60.0 - 70.0' **Shale and siltstones**
 Mix of shale (70%-80%) and siltstones(20%-10%) in clay matrix. Sub-angular to sub-rounded moderately oxidized shale, sub rounded siltstone. 20-30 gpm.

70.0 - 100.0' **Shale**
 Light gray sub-angular to sub-rounded highly weathered shale with 30%-40% oxidized facies in ~5% clay matrix. 10% gossan. 40-45 gpm at 90'.

100.0 - 130.0' **Shale**
 Dark gray angular shale, <10% oxidized facies. Some disseminated sulfides. 40-45 gpm.

130.0 - 150.0' **Shale**
 Dark gray angular/sub-angular shale with white quartzite inclusions. Abundant disseminated sulfides with occasional massive sulfides. 40-45 gpm.

150.0 - 190.0' **Shale**
 Dark gray angular shale with disseminated sulfides with occasional massive sulfides. ~10% angular yellow siltstone. 40-45 gpm.

190.0 - 230.0' **Shale and barite**
 Light gray sub-angular shale with 10%-30% barite inclusions. Considerable massive pyrite and chalcopryrite increasing with depth. Occasional specks of copper. 50-75 gpm at 200'.

230.0 - 250.0' **Shale**
 Light gray sub-angular shale with extensive disseminated sulfides and some massive sulfides. 50-75 gpm.

250.0 - 260.0' **Shale**
 Light gray sub-angular shale mixed with dark gray sub-angular shale with quartzite inclusions. 50-75 gpm.

260.0 - 270.0' **Shale**
 Mostly dark gray angular/sub-angular shale with some light gray sub-angular shale. Fewer disseminated sulfides and massive sulfides. 50-75 gpm.

270.0 - 290.0' **Shale**
 Mostly light gray sub-angular shale with ~20% dark gray sub-angular shale. Extensive disseminated sulfides and moderate massive sulfides. 50-75 gpm.

290.0 - 310.0' **Shale**
 Mostly light gray sub-angular shale with ~20% dark gray sub-angular shale. Extensive disseminated sulfides and extensive massive sulfides. 75-100 gpm.

310.0 - 320.0' **Shale**

WELL CONSTRUCTION

SAMPLE NOTES

GRAPHICS

GEOLOGICAL DESCRIPTION

Mostly dark gray angular/sub-angular shale with some (20%) light gray angular/sub-angular shale. Decreasing disseminated sulfides and massive sulfides. 75-100 gpm.

320.0 - 360.0' **Shale**

Dark gray sub-angular shale. Some infrequent disseminated and massive pyrite. 75-100 gpm.

360.0 - 370.0' **Shale**

Black shale with little disseminated sulfides but some massive sulfides. 100 gpm.

MONTANA WELL LOG REPORT

Form No. 603 R2-04

Well ID# 5C15-194

This log reports the activities of a licensed Montana well driller and serves as the official record of work done within the borehole and casing and describes the amount of water encountered. **This form is to be completed by the driller and filed with MBMG within 60 days of completion of the work.** Acquiring Water Rights is the well owner's responsibility and is not accomplished by the filing of this report.

Well log information is stored in the Groundwater Information Center at the Montana Bureau of Mines and Geology (Butte) and water right information is stored in the Water Rights Bureau records (Helena).

For fields that are not applicable, enter NA. Record additional information in the REMARKS section.

MONTANA WELL LOG REPORT

Form No. 603 R2-04

Well ID# 3C15-185

This log reports the activities of a licensed Montana well driller and serves as the official record of work done within the borehole and casing and describes the amount of water encountered. **This form is to be completed by the driller and filed with MBMG within 60 days of completion of the work.** Acquiring Water Rights is the well owner's responsibility and is not accomplished by the filing of this report.

Well log information is stored in the Groundwater Information Center at the Montana Bureau of Mines and Geology (Butte) and water right information is stored in the Water Rights Bureau records (Helena).

For fields that are not applicable, enter NA. Record additional information in the REMARKS section.

1. WELL OWNER:

Name TINTINA ALASKA EXPLORATION, INC
 Mailing address 17 EAST MAIN
WHITE SULPHUR SPRINGS, MT 59645

2. WELL LOCATION:

List ¼ from smallest to largest
 _____ ¼ _____ ¼ NE ¼ NW ¼, Section 36
 Township 2NS Range 6EW County MEADEL
 Lot _____, Tract/Blk _____ Subdivision Name _____
 Certificate of Survey _____
 Well Address _____
 GPS Yes No
 Latitude N 45° 45.922 Longitude W 110° 55.005
 Error as reported by GPS locator (± feet) 9 FT
 Horizontal datum NAD27 WGS84

3. PROPOSED USE:

Domestic Stock Irrigation
 Public water supply Monitoring Well
 Geothermal Closed System Open System ReInjection
 Extraction H₂O Temp _____ Number of Wells in System _____
 Other: _____

4. TYPE OF WORK:

New well Deepen existing well Abandon existing well
 Method: Cable Rotary Other: CURE

5. WELL CONSTRUCTION DETAILS:

Borehole:
 Dia. 6 in. from 0 ft. to 15 ft.
 Dia. 15 in. from 15 ft. to 99 ft.
 Dia. _____ in. from _____ ft. to _____ ft.

Casing:
 Steel: Wall thickness _____ Threaded Welded
 Dia. _____ in. from _____ ft. to _____ ft.
 Dia. _____ in. from _____ ft. to _____ ft.
 Casing Shoe: Yes No

Plastic: Pressure Rating 5.40 lbs. Threaded Welded
 Dia. 1.5 in. from 8+2 ft. to 60.0 ft.

Perforations/Slotted Pipe:
 Type of perforator used _____
 Size of perforations/slots _____ in. by _____ in.
 _____ no. of perforations/slots from _____ ft. to _____ ft.
 _____ no. of perforations/slots from _____ ft. to _____ ft.

Screens: Yes No
 Material PVC
 Dia. 1.5 Slot size 0.020 from 60.0 ft. to 80.0 ft.
 Dia. _____ Slot size _____ from _____ ft. to _____ ft.

Gravel Packed: Yes No
 Size of gravel 10/20
 Gravel placed from 56.3 ft. to 85 ft.

Packer: Yes No
 Type _____ Depth(s) _____

Grout: Material used BENTONITE GROUT
 Depth from _____ ft. to _____ ft. OR Continuous feed

6. WELL TEST DATA:

A well test is required for all wells. (See details on well log report cover.)
 Static water level 26 ft. below top of casing or
 Closed-in artesian pressure _____ psi.
 How was test flow measured:
 bucket/stopwatch, weir, flume, flowmeter, etc _____
 Yellowstone Controlled Groundwater Area - Water Temperature _____ °F
 AQUIFER TEST DATA FORM ATTACHED

Test - 1 hour minimum

Drawdown is the amount water level is lowered below static level.
 All depth measurements shall be from the top of the well casing.
 Time of recovery is hours/minutes since pumping stopped.

Air test*
 _____ gpm with drill stem set at _____ ft. for _____ hours
 Time of recovery _____ hrs/min. Recovery water level _____ ft.

OR Bailer test*

_____ gpm with _____ ft. of drawdown after _____ hours
 Time of recovery _____ hrs/min. Recovery water level _____ ft.

OR Pump test*

Depth pump set for test _____ ft.
 _____ gpm pump rate with _____ ft. of drawdown after _____ hrs pumping
 Time of recovery _____ hrs/min. Recovery water level _____ ft.

OR Flowing Artesian*

_____ gpm for _____ hours
 Flow controlled by _____

**During the well test the discharge rate shall be as uniform as possible. This rate may or may not be the sustainable yield of the well. Sustainable yield does not include the reservoir of the well casing.*

7. WELL LOG: Record depth(s) that water is encountered.

Depth, Foot		Material: color/rock and type/descriptor (example: blue/shale/hard, or brown/gravel/water, or brown/sand/heaving)
From	To	
<u>0</u>	<u>4</u>	<u>SOIL</u>
<u>4</u>	<u>99</u>	<u>GRANODIORITE</u>

Mr. Greg Bryce
Hydrometrics, Inc.
3020 Bozeman Ave.
Helena, MT 59601

RE: Black Butte Copper Project-Laboratory Testing

Dear Mr. Bryce,

On April 16, 2015, five samples were delivered to Pioneer Technical Service's Bozeman, MT laboratory. The samples were referenced as SC11-008, SC11-036, SC12-129, SC14-164, and SC14-170. The samples were given Lab Nos. G15247 through G15251, respectively. The requested testing was performed in accordance with the following Standards:

- Standard Proctor (ASTM D698), and
- Hydraulic Conductivity of Saturated Porous Material Using a Flexible Wall Permeameter (ASTM D5084).

Table 1

Lab No.	Sample Identification	Confining Pressure (psi)	Hydraulic Conductivity cm/sec
G15247	SC11-008	34.6	1.0×10^{-08}
G15248	SC11-036	37.2	8.1×10^{-09}
G15249	SC12-129	42.0	5.4×10^{-09}
G15250	SC14-164	50.0	2.1×10^{-08}
G15251	SC14-170	41.3	2.5×10^{-07}

At the request of Hydrometrics, the hydraulic conductivity samples were re-molded by compacting the specimens at optimum moisture to a dry unit weight equal to 95% of the uncorrected proctor value. Hydrometrics also requested that the maximum confining pressure was applied after saturation.

The hydraulic conductivity values and confining pressures are provided in Table 1. The moisture-density (proctor) curves and hydraulic conductivity sheets are attached with this report. Thank you for using Pioneer for your geotechnical testing requirements. Please contact us at (406)388-8578 if you have any questions or require any additional information regarding this report.

Sincerely,
PIONEER TECHNICAL SERVICES, INC.

Niki Griffis
Project Scientist/Laboratory Manager

Jeffrey Riedel, P.E.
Senior Geotechnical Engineer
