EXECUTIVE SUMMARY

The performance monitoring program evaluates the progress of remedial actions in the Streamside Tailings Operable Unit (SSTOU) of Silver Bow Creek. Environmental media monitored in 2018 included surface water, instream sediment, groundwater, vadose zone water, macroinvertebrates, periphyton, and stream geomorphology. This report summarizes results of data collected for each of these environmental media and evaluates progress toward attainment of performance goals as of 2018.[1]

For more than a century, from the 1870s through the 1980s, Silver Bow Creek received direct and indirect waste rock, slag (smelting byproduct), mill tailings, contaminated groundwater [Chadwick et al., 1985; Luoma et al. 2005], and raw municipal sewage inputs. An estimated 2 million cubic meters of tailings were deposited directly into the stream [Luoma et al., 2005]. Prior to remediation, streamside tailings deposits were distributed along the entire length of the stream [Brook and Moore, 1989], and localized deposit depths exceeded 5 meters (m). Much of the floodplain was devoid of vegetation due to the toxicity of floodplain tailings [Luoma et al., 2005]. Throughout the mining period (c., 1870 to 1982), the stream was utilized primarily as a sewer for the removal of industrial wastes.

In November 1995, Montana Department of Environmental Quality (DEQ) and the U.S. Environmental Protection Agency (USEPA) issued a Record of Decision (ROD) for Silver Bow Creek [DEQ and USEPA, 1995] that identified the final site remedy and the agencies' rationale for selecting that remedy. The major remedial actions that resulted from the ROD included excavation of tailings and related impacted soils from the floodplain of Silver Bow Creek, and the subsequent reconstruction of the stream channel and floodplain.

The portion of Silver Bow Creek, and the adjacent floodplain, undergoing remediation under the consent decree settlement [Montana v. AR, 1998] is designated as the SSTOU. The SSTOU is divided into four subareas based upon geologic and topographic features that control soil, hydrogeologic, geomorphic, surface water, ecological, demographic, and land use characteristics of the SSTOU [DEQ and USEPA, 1995]. Each remedial subarea is further divided into five remedial reaches, each approximately one mile in length, for a total of 20 remedial reaches within the SSTOU which are identified longitudinally from upstream to downstream by the letters A-T.

[1] The Record of Decision (ROD) identifies remediation goals and performance standards for surface water and groundwater. The performance monitoring program for the SSTOU evaluates a broader range of parameters than these ROD-required performance standards. The performance monitoring program identifies performance goals for the other parameters as a means of effectively discussing and evaluating the effectiveness of the remedy and restoration actions taken in the SSTOU. Use of the term "performance goal" or similar terms in this or other monitoring plans or reports is not intended to make each goal a ROD-required remediation goal or performance standard.

Remedial actions include excavation of tailings and contaminated soils from the Silver Bow Creek floodplain, removal of those soils to a local repository or to the Opportunity Ponds, replacement of removed tailings with clean fill material, native grass seeding, some willow and shrub plantings, and complete channel reconstruction [USEPA, 2011]. Restoration actions involve various habitat improvements that include the addition of organic matter to the borrow soils and additional plant revegetation and aquatic habitat components [NRDP, 2005]. As of 2018, major remedial activity is complete in all Subareas of the SSTOU. Additional repairs and removal of remnant tailings in Subareas 1 and 2 occurred from 2016 through 2018.

Performance goals referenced in this report for surface water contaminants of concern (COC) were those specified by the SSTOU ROD. Specifically, the performance goal is for all samples collected in the SSTOU to "meet the more restrictive aquatic life or human health standards for surface water identified in DEQ Circular WQB-7, through application of I-classification requirements" [DEQ and USEPA, 1995]. The SSTOU ROD also specified that surface water monitoring should be conducted quarterly and identified a suite of water chemistry parameters to be monitored, including six metal contaminants of concern (COCs): arsenic, cadmium, copper, lead, mercury, and zinc. In 2018, 16 sites were included in the monitoring network, including all sites specified by the SSTOU ROD. Twelve sites were sampled in the SSTOU. These sites were supplemented with two sites in Silver Bow Creek that represent previously contaminated and subsequently remediated portions of Silver Bow Creek located immediately upstream from the SSTOU in the "Lower Area One" (LAO) portion of the Butte Priority Soils Operable Unit. In addition, two sites were sampled in tributary streams (German Gulch and Blacktail Creek) which are located within the watershed, but outside the area of primary contamination.

Surface water monitoring results over the 2010-2018 time period demonstrate some evidence that remedial actions have resulted in reduced COC concentrations and variability during this recent time frame. It should also be noted that peak spring runoff streamflow levels in 2018 were among the highest in the SSTOU over the past 20 years and since remediation efforts began. It is expected for some mobilization of bed sediments and associated sediment-bound contaminants to occur during these high peak flow events. Variability associated with natural systems can confound the ability to distinguish trends in the short term, which is part of the reason for long term monitoring.

In Subareas 1 and 2, concentrations at most sites have remained relatively level since 2010 and variability appears to be low. At sites in Subareas 3 and 4, particularly sites near the German Gulch confluence (Subarea 3) and at Opportunity (Subarea 4), total recoverable COC concentrations have demonstrated a steady decline. However, despite improvements, exceedances of surface water performance goals were common in 2018 in each subarea.

Copper was the COC which most commonly exceeded the surface water performance goals in 2018. Copper exceeded the performance goal at every SSTOU site in 2018 during at least one quarter and at three sites copper exceeded the performance goal during each quarter. Overall, copper concentrations exceeded the performance goal in 77 percent (37 of 48) of the SSTOU

samples. The proportion of SSTOU samples (n = 48) which exceeded the performance goals for other total recoverable metal COC concentrations, in order of frequency, were mercury and arsenic (each 42 percent), lead and zinc (each 4 percent), and cadmium (0 percent).

Since the 2016 upgrades to the WWTP, a substantial decrease in some nutrient concentrations has been observed in Silver Bow Creek below the WWTP. This is most evident in ammonia concentrations, for which concentrations were below the detection limit in all 2018 quarters except Q1. The high concentrations observed in Q1 at all Silver Bow Creek sites downstream from the WWTP suggested some disruption or change in treatment processes occurred at the plant during that monitoring period. In contrast, prior to 2016, ammonia concentrations were commonly several orders of magnitude greater than the reporting limit. Total nitrogen, and nitrate plus nitrite concentrations in 2018 increased sharply at the WWTP but returned to levels similar to, or lower than, background concentrations. Total phosphorus concentrations did not increase sharply at the Butte WWTP in 2018 as had occurred during nearly all previous monitoring periods prior to the upgrades in 2016, suggesting the WWTP may have improved their ability to control phosphorus loading. However, despite the upgrades, total nitrogen and total phosphorus concentrations remained well above the DEQ standards both above and below the WWTP.

Performance goals were not identified for instream sediment COCs in the SSTOU ROD [DEQ and USEPA, 1995]. The 1998 Explanation of Significant Differences [DEQ and USEPA, 1998] adopted criteria for sediment removal which provided for removal of the contaminated streambed material and replacement with clean material throughout the operable unit. In lieu of specific numeric performance goals for instream sediment, this monitoring program has identified consensus-based sediment quality guidelines including the "threshold effect concentrations" (TECs) and "probable effect concentrations" ([PECs) from MacDonald et al. [2000]. In addition to comparing sediment COC concentrations to those reference values, sediment monitoring in the SSTOU is conducted to determine the extent to which the streambed may be re-contaminated from upstream or other sources. As with surface water, the SSTOU ROD also specified that instream sediment monitoring be conducted quarterly at each surface water sampling site for each COC. Sediment samples were analyzed for COC concentrations in three size fractions (<0.063 mm, 0.063-1 mm, and 1-2 mm) and for the weighted mean concentration among those size fractions.

Weighted mean sediment COC concentrations in the SSTOU exceeded the TEC (and often PEC) reference values at virtually all sites in 2018 for copper and other COCs. However, the highest concentrations for copper and most other COCs in sediment often occurred at the LAO sites in the vicinity of the Slag Canyon in Butte (upstream from the SSTOU). Downstream from the Slag Canyon, sediment COC concentrations tended to decrease rapidly through Subarea 1 and were lowest in Silver Bow Creek in Subarea 2. Concentrations in Subarea 3, particularly below German Gulch were also high, then tended to decrease through Subarea 4.

As with surface water, the SSTOU ROD defined the performance goals for groundwater quality as having COC concentrations which, "Attain compliance with applicable Circular WQB-7 standards, federal Maximum Contaminant Levels (MCLs) and federal nonzero Maximum Contaminant Level Goals (MCLGs) for all SSTOU groundwater." Moreover, "The groundwater levels to be attained consist of the more stringent of the MCL, any nonzero MCLG, or the WQB-7 human health standard for each parameter." Groundwater was monitored at 27 wells located in nine well clusters including 18 monitoring wells and nine background wells. Nine well clusters were located in the Silver Bow Creek floodplain and one cluster was located near the Mine Waste Relocation Repository (MWRR). Wells located in the MWRR were monitored during July and October of 2018, whereas the rest of the sites were monitored during October only.

In the floodplain well clusters in 2018, several COCs (arsenic, cadmium, copper, lead, and zinc) exceeded the performance goals in at least one monitoring well. Arsenic was the only COC which exceeded performance goals in background wells. Of the samples collected from the monitoring wells located in the floodplain clusters (n = 18), 17 percent exceeded the arsenic performance goal, 39 percent exceeded the cadmium performance goal, 6 percent exceeded the copper performance goal, 6 percent exceeded the lead performance goal, and 39 percent exceeded the zinc performance goal. In the MWRR cluster, one out of five monitoring wells (25 percent) had a sample with an arsenic concentration that exceeded the performance goals. However, it is worth noting that the MWRR cluster background well samples also exceeded the arsenic standard during both sampling events.

Vadose zone water quality is monitored in the vicinity of the MWRR to assess mobility of COCs from the repository into the underlying groundwater supply and surface water in the SSTOU. As with groundwater monitoring in the MWRR, vadose zone water was monitored in July and October utilizing eight soil lysimeters (seven monitoring lysimeters and one background lysimeter). Monitoring at these same lysimeters has occurred each year since 2010. Performance goals were not established in the SSTOU ROD for vadose zone water. Instead, COC concentrations and other parameters (other metals, common ions, and physical parameters) are monitored to assess if any COC concentrations appear to be increasing which would potentially indicate leaching of COCs from the repository.

Based on a 9-year time series, there was no compelling evidence that COC concentrations may be increasing in vadose zone water with a couple minor exceptions. Two lysimeters showed some evidence of increasing COC concentrations through time. One lysimeter showed some evidence of increasing arsenic concentrations, and another showed some evidence of increasing copper concentration. However, these trends were not strong and weren't consistent for other COCs. This suggests that the results of the trend test may be spurious (i.e., Type I error or "false positive") and we are not confident that the repository was in fact leaching COCs in 2018. Continued monitoring of vadose zone chemistry near the repository appears to be warranted, and concentrations in both lysimeters will be monitored in future years to look for continued increasing trends. One lysimeter, damaged in 2017, was was discontinued and replaced in 2018.

Biological (macroinvertebrate and periphyton) samples were collected at each surface water sampling site during the third quarter of 2018. As with other environmental media monitored which did not have ROD-specified performance goals, reference values from specific bioindices are used to evaluate macroinvertebrate and periphyton biointegrity. Among other bioassessment indices, the Montana Valley and Foothill Prairies (MVFP) bioassessment index [Bollman, 1998] was used to evaluate macroinvertebrate biointegrity in the SSTOU. Except for one site, which was "severely" impaired, all SSTOU sites were classified as "moderately" impaired for macroinvertebrate biointegrity (MVFP scores ranged from 17-50 percent). In the four sites monitored outside the SSTOU, impairment scores ranged from 22 percent "moderate" (LAO sites) to 83 percent "non-impaired" (tributary sites). Stressors implicated as likely impairments to macroinvertebrate biointegrity in the 12 SSTOU sites included nutrients (4 sites), habitat disturbance (2 sites), sediments (4 sites), and hypoxia (7 sites). Metals were implicated as a likely stressor to the macroinvertebrate assemblage at two sites in 2018.

Periphyton samples were evaluated for an array of metrics and bioindices to evaluate impairments from specific stressors such as metals, nutrients, and sediment. One set of bioindices, the increaser taxa bioindices, produce impairment probabilities based on the relative abundance of sampled taxa which are believed to be tolerant or sensitive to particular stressor conditions. Among the 12 SSTOU sites, the probabilities of impairment ranged from 26 to 88 percent for nutrients, from 3 to 13 percent for metals, and from 28 to 95 percent for sediments.

Total phosphorus concentrations (mg/L) at selected Silver Bow Creek sites in the Streamside Tailings Operable Unit: above Butte WWTP (Site SS-06G), below Butte WWTP (Site SS-07), at Rocker (Site SS-08), above Sand Creek (Site SS-10A), at Miles Crossing (Site SS-14), and at Opportunity (Site SS-17D). Red line represents the total phosphorus standard [DEQ, 2014]. 38

Figure 1-30. Total recoverable arsenic concentrations at Streamside Tailings Operable Unit monitoring stations, 2018. Red line represents the human health surface water standard [DEQ, 2017]. 41

Figure 1-31. Total recoverable arsenic concentrations (mg/L) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Red line represents the human health surface water standard [DEQ, 2017]. . 42

Figure 1-32. Total recoverable arsenic concentrations (mg/L) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Red line represents the human health surface water standard [DEQ, 2017]. 43

Figure 1-33. Total recoverable arsenic concentrations (mg/L) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Sand Creek (Site SS-10B), Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at

Miles Crossing (Site SS-14). Red line represents the human health surface water standard [DEQ, 2017]. 44

Figure 1-34. Total recoverable arsenic concentrations (mg/L) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-15A-2) and below (Site SS-15B) German Gulch. Red line represents the human health surface water standard [DEQ, 2017]. 45

Figure 1-35. Total recoverable arsenic concentrations (mg/L) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Red line represents the human health surface water standard [DEQ, 2017]. 46

Figure 1-36. Total recoverable cadmium concentrations at Streamside Tailings Operable Unit monitoring stations, 2018. No samples exceeded the chronic aquatic life standard [DEQ, 2017]. 48

Figure 1-37. Total recoverable cadmium concentrations (mg/L) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017]. 49

Figure 1-38. Total recoverable cadmium concentrations (mg/L) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017]. 50

Figure 1-39. Total recoverable cadmium concentrations (mg/L) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Sand Creek (Site SS-10B), Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017]. 51

Figure 1-40. Total recoverable cadmium concentrations (mg/L) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-15A-2) and below (Site SS-15B) German Gulch. Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017]. 52

Figure 1-41. Total recoverable cadmium concentrations (mg/L) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017]. 53

Figure 1-42. Total recoverable copper concentrations at Streamside Tailings Operable Unit monitoring stations, 2018. Colored symbols represent samples exceeding the chronic (yellow) and acute (red) aquatic life standards [DEQ, 2017]. 56

Figure 1-43. Total recoverable copper concentrations (mg/L) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow

Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017]. 57

Figure 1-44. Total recoverable copper concentrations (mg/L) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017]. 58

Figure 1-45. Total recoverable copper concentrations (mg/L) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Sand Creek (Site SS-10B), Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017]..... 59

Figure 1-46. Total recoverable copper concentrations (mg/L) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-15A-2), and below (Site SS-15B) German Gulch. Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017]..... 60

Figure 1-47. Total recoverable copper concentrations (mg/L) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017]. 61

Figure 1-48. Total recoverable lead concentrations at Streamside Tailings Operable Unit monitoring stations, 2018. Yellow symbols represent samples exceeding the chronic aquatic life standard [DEQ, 2017]..... 64

Figure 1-49. Total recoverable lead concentrations (mg/L) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017]. 65

Figure 1-50. Total recoverable lead concentrations (mg/L) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017]..... 66

Figure 1-51. Total recoverable lead concentrations (mg/L) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Sand Creek (Site SS-10B), Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017]..... 67

Figure 1-52. Total recoverable lead concentrations (mg/L) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-15A-2) and below (Site SS-15B) German Gulch. Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017]. 68

Figure 1-53. Total recoverable lead concentrations (mg/L) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017]....69

Figure 1-54. Total recoverable mercury concentrations at Streamside Tailings Operable Unit monitoring stations, 2018. Red line represents the chronic aquatic life standard [MDHES, 1994]....72

Figure 1-55. Total recoverable mercury concentrations in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Red line represents the chronic aquatic life standard [MDHES, 1994]. 73

Figure 1-56. Total recoverable mercury concentrations in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Red line represents the chronic aquatic life standard [MDHES, 1994]....74

Figure 1-57. Total recoverable mercury concentrations in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Sand Creek (Site SS-10B), Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Red line represents the chronic aquatic life standard [MDHES, 1994]. 75

Figure 1-58. Total recoverable mercury concentrations in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-15A-2) and below (Site SS-15B) German Gulch. Red line represents the chronic aquatic life standard [MDHES, 1994]....76

Figure 1-59. Total recoverable mercury concentrations in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Red line represents the chronic aquatic life standard [MDHES, 1994]. 77

Figure 1-63. Total recoverable zinc concentrations (mg/L) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Sand Creek (Site SS-10B), Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [MDHES, 1994]. 82

Figure 1-64. Total recoverable zinc concentrations (mg/L) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-15A-2) and below (Site SS-15B) German Gulch. Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [MDHES, 1994]. 83

Figure 1-65. Total recoverable zinc concentrations (mg/L) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [MDHES, 1994]. 84

Figure 2-1. Instream sediment sampling locations in the Streamside Tailings Operable Unit. 99

Figure 2-2. Instream sediment sampling locations in the vicinity of the German Gulch confluence in the Streamside Tailings Operable Unit. The reach of the Silver Bow Creek stream channel highlighted in red was not remediated due to limited access and the relatively low estimated tailings volume. 100

Figure 2-3. Silver Bow Creek and Blacktail Creek instream sediment sampling locations in the vicinity of the Slag Canyon (highlighted in yellow) and the Metro Storm Drain (i.e., Silver Bow Creek) and Blacktail Creek confluence in Butte, Montana. 101

Figure 2-4. Total arsenic concentrations in instream sediment (<0.063 mm) samples collected at Streamside Tailings Operable Unit monitoring stations, 2018. Solid red line is the 33 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 9.79 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 111

Figure 2-5. Fine fraction (<0.063 mm) total dry-weight arsenic concentrations (mg/kg-DW) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Blacktail Creek at Metro Storm Drain Confluence (Site SS-04), Silver Bow Creek in Slag Canyon (SLAG-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Solid red line is the 33 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 9.79 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 112

Figure 2-6. Fine fraction (<0.063 mm) total dry-weight arsenic concentrations (mg/kg-DW) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Solid red line is the 33 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 9.79 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 113

Figure 2-7. Fine fraction (<0.063 mm) total dry-weight arsenic concentrations (mg/kg-DW) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow

Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Solid red line is the 33 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 9.79 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 114

Figure 2-8. Fine fraction (<0.063 mm) total dry-weight arsenic concentrations (mg/kg-DW) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above German Gulch (Alternate Site, Site SS-15A-2), Silver Bow Creek above (Site SS-15A) and below (Site SS-15B) German Gulch. Solid red line is the 33 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 9.79 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 115

Figure 2-9. Fine fraction (<0.063 mm) total dry-weight arsenic concentrations (mg/kg-DW) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Solid red line is the 33 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 9.79 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 116

Figure 2-10. Total cadmium concentrations in instream sediment (<0.063 mm) samples collected at Streamside Tailings Operable Unit monitoring stations, 2018. Solid red line is the 4.98 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.99 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 121

Figure 2-11. Fine fraction (<0.063 mm) total dry-weight cadmium concentrations (mg/kg-DW) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Blacktail Creek at Metro Storm Drain Confluence (Site SS-04), Silver Bow Creek in Slag Canyon (SLAG-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Solid red line is the 4.98 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.99 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. Samples with concentrations below the analytical reporting limit (RL) are represented with concentrations at half the RL. 122

Figure 2-12. Fine fraction (<0.063 mm) total dry-weight cadmium concentrations (mg/kg-DW) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Solid red line is the 4.98 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.99 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 123

Figure 2-13. Fine fraction (<0.063 mm) total dry-weight cadmium concentrations (mg/kg-DW) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Solid red line is the 4.98 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.99 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 124

Figure 2-14. Fine fraction (<0.063 mm) total dry-weight cadmium concentrations (mg/kg-DW) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above German Gulch (Alternate Site, Site SS-15A-2), Silver Bow Creek above (Site SS-15A) and below (Site SS-15B) German Gulch. Solid red line is the

4.98 mg/kg-DW “probable effect concentration” (PEC) and the dashed red line is the 0.99 mg/kg-DW “threshold effect concentration” (TEC) [MacDonald et al., 2000]. 125

Figure 2-15. Fine fraction (<0.063 mm) total dry-weight cadmium concentrations (mg/kg-DW) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Solid red line is the 4.98 mg/kg-DW “probable effect concentration” (PEC) and the dashed red line is the 0.99 mg/kg-DW “threshold effect concentration” (TEC) [MacDonald et al., 2000]. 126

Figure 2-16. Total copper concentrations in instream sediment (<0.063 mm) samples collected at Streamside Tailings Operable Unit monitoring stations, 2018. Solid red line is the 149 mg/kg-DW “probable effect concentration” (PEC) and the dashed red line is the 31.6 mg/kg-DW “threshold effect concentration” (TEC) [MacDonald et al., 2000]. 131

Figure 2-17. Fine fraction (<0.063 mm) total dry-weight copper concentrations (mg/kg-DW) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Blacktail Creek at Metro Storm Drain Confluence (Site SS-04), Silver Bow Creek in Slag Canyon (SLAG-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Solid red line is the 149 mg/kg-DW “probable effect concentration” (PEC) and the dashed red line is the 31.6 mg/kg-DW “threshold effect concentration” (TEC) [MacDonald et al., 2000]. 132

Figure 2-18. Fine fraction (<0.063 mm) total dry-weight copper concentrations (mg/kg-DW) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Solid red line is the 149 mg/kg-DW “probable effect concentration” (PEC) and the dashed red line is the 31.6 mg/kg-DW “threshold effect concentration” (TEC) [MacDonald et al., 2000]. 133

Figure 2-19. Fine fraction (<0.063 mm) total dry-weight copper concentrations (mg/kg-DW) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Solid red line is the 149 mg/kg-DW “probable effect concentration” (PEC) and the dashed red line is the 31.6 mg/kg-DW “threshold effect concentration” (TEC) [MacDonald et al., 2000]. 134

Figure 2-20. Fine fraction (<0.063 mm) total dry-weight copper concentrations (mg/kg-DW) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above German Gulch (Alternate Site, Site SS-15A-2), Silver Bow Creek above (Site SS-15A) and below (Site SS-15B) German Gulch. Solid red line is the 149 mg/kg-DW “probable effect concentration” (PEC) and the dashed red line is the 31.6 mg/kg-DW “threshold effect concentration” (TEC) [MacDonald et al., 2000]. 135

Figure 2-21. Fine fraction (<0.063 mm) total dry-weight copper concentrations (mg/kg-DW) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Solid red line is the 149 mg/kg-DW “probable effect concentration” (PEC) and the dashed red line is the 31.6 mg/kg-DW “threshold effect concentration” (TEC) [MacDonald et al., 2000]. 136

Figure 2-22. Total lead concentrations in instream sediment (<0.065 mm) samples collected at Streamside Tailings Operable Unit monitoring stations, 2018. Solid red line is the 128 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 35.8 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 141

Figure 2-23. Fine fraction (<0.063 mm) total dry-weight lead concentrations (mg/kg-DW) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Blacktail Creek at Metro Storm Drain Confluence (Site SS-04), Silver Bow Creek in Slag Canyon (SLAG-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Solid red line is the 128 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 35.8 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 142

Figure 2-24. Fine fraction (<0.063 mm) total dry-weight lead concentrations (mg/kg-DW) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Solid red line is the 128 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 35.8 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 143

Figure 2-25. Fine fraction (<0.063 mm) total dry-weight lead concentrations (mg/kg-DW) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Solid red line is the 128 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 35.8 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 144

Figure 2-26. Fine fraction (<0.063 mm) total dry-weight lead concentrations (mg/kg-DW) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above German Gulch (Alternate Site, Site SS-15A-2), Silver Bow Creek above (Site SS-15A) and below (Site SS-15B) German Gulch. Solid red line is the 128 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 35.8 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 145

Figure 2-27. Fine fraction (<0.063 mm) total dry-weight lead concentrations (mg/kg-DW) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Solid red line is the 128 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 35.8 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 146

Figure 2-28. Total mercury concentrations in instream sediment (<0.063 mm) samples collected at Streamside Tailings Operable Unit monitoring stations, 2018. The upper whisker of Site SS-15A extends to 17 mg/kg. Solid red line is the 1.06 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.18 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 151

Figure 2-29. Fine fraction (<0.063 mm) total dry-weight mercury concentrations (mg/kg-DW) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Blacktail Creek at Metro Storm Drain Confluence

(Site SS-04), and Silver Bow Creek in Slag Canyon (SLAG-01) were not analyzed for mercury. Solid red line is the 1.06 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.18 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 152

Figure 2-30. Fine fraction (<0.063 mm) total dry-weight mercury concentrations (mg/kg-DW) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Solid red line is the 1.06 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.18 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 153

Figure 2-31. Fine fraction (<0.063 mm) total dry-weight mercury concentrations (mg/kg-DW) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Solid red line is the 1.06 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.18 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 154

Figure 2-32. Fine fraction (<0.063 mm) total dry-weight mercury concentrations (mg/kg-DW) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above German Gulch (Alternate Site, Site SS-15A-2), Silver Bow Creek above (Site SS-15A) and below (Site SS-15B) Solid red line is the 1.06 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.18 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 155

Figure 2-33. Fine fraction (<0.063 mm) total dry-weight mercury concentrations (mg/kg-DW) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Solid red line is the 1.06 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.18 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 156

Figure 2-34. Total zinc concentrations in instream sediment (<0.063 mm) samples collected at Streamside Tailings Operable Unit monitoring stations, 2018. Solid red line is the 459 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 121 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 161

Figure 2-35. Fine fraction (<0.063 mm) total dry-weight zinc concentrations (mg/kg-DW) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Blacktail Creek at Metro Storm Drain Confluence (Site SS-04), Silver Bow Creek in Slag Canyon (SLAG-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Solid red line is the 459 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 121 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 162

Figure 2-36. Fine fraction (<0.063 mm) total dry-weight zinc concentrations (mg/kg-DW) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Solid red line is the 459 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 121 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 163

Figure 2-37. Fine fraction (<0.063 mm) total dry-weight zinc concentrations (mg/kg-DW) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Solid red line is the 459 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 121 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 164

Figure 2-38. Fine fraction (<0.063 mm) total dry-weight zinc concentrations (mg/kg-DW) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above German Gulch (Alternate Site, Site SS-15A-2), Silver Bow Creek above (Site SS-15A) and below (Site SS-15B) German Gulch. Solid red line is the 459 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 121 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 165

Figure 2-39. Fine fraction (<0.063 mm) total dry-weight zinc concentrations (mg/kg-DW) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Solid red line is the 459 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 121 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. 166

1.0 SURFACE WATER

1.1 INTRODUCTION

This chapter describes the results of surface water monitoring activities conducted in 2018 to assess the effectiveness of remedial actions implemented within the Streamside Tailings Operable Unit (SSTOU) of the Silver Bow Creek/Butte Area National Priorities List site (Figure 1-1). Data were collected to describe the effects of remedial actions on surface water quality and to gage progress toward attainment of performance goals.

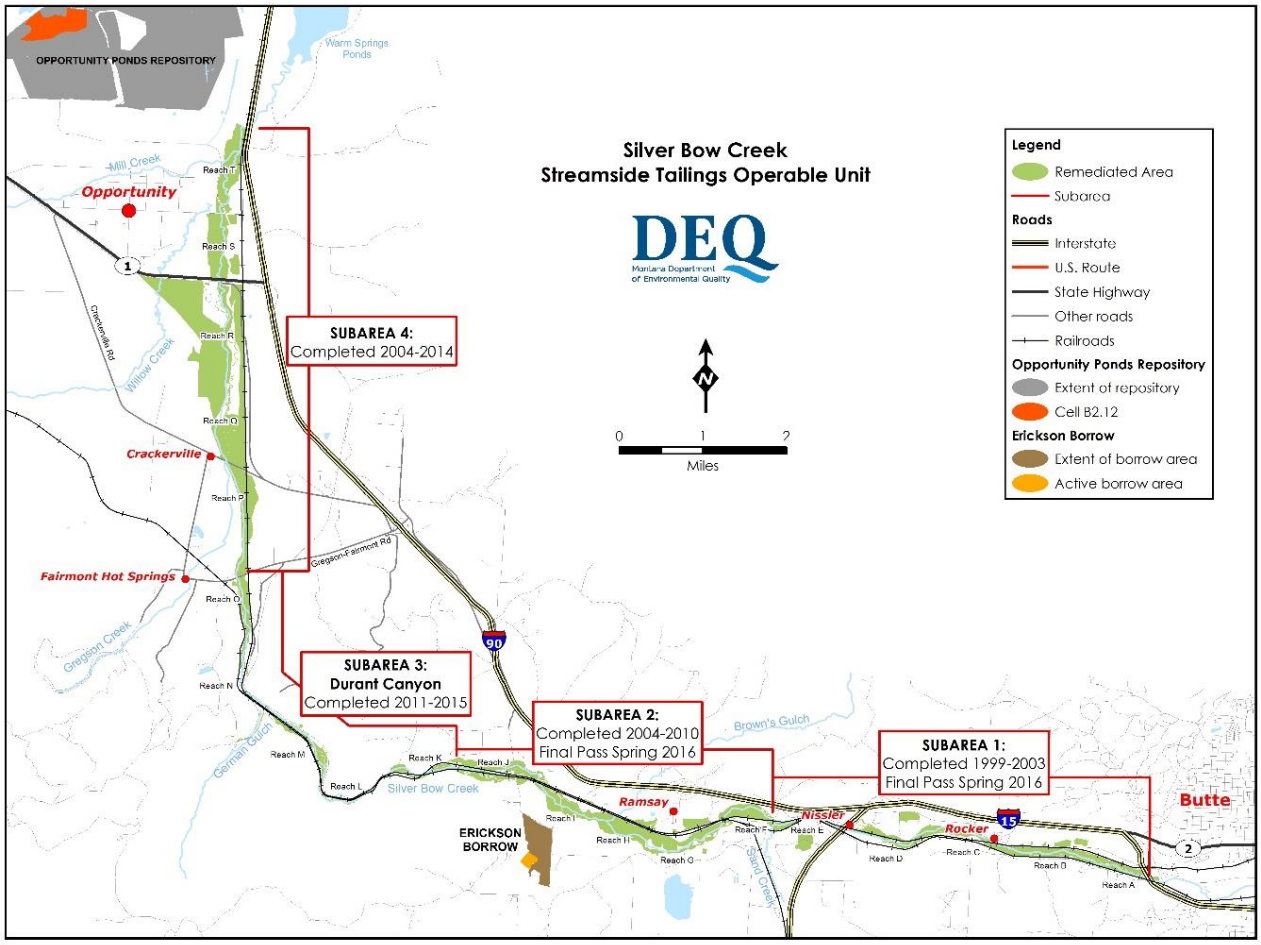

Figure 1-1. Remedial subareas of the Streamside Tailings Operable Unit.

1.2 PERFORMANCE GOALS

The SSTOU Record of Decision (ROD) specified that the final remediation goal for contaminant of concern (COC) concentrations in surface waters was to "meet the more restrictive of aquatic life or human health standards for surface water identified in DEQ Circular WQB-7, through application of I-classification requirements" [DEQ and USEPA, 1995]. Since the issuance of the ROD, Circular WQB-7 [MDHES, 1994] has been replaced by Circular DEQ-7 [DEQ, 2017], and standards for some COCs have been revised. The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and the National Contingency Plan (NCP) provide for use of the new, more stringent standards where compliance with the new standard is necessary to ensure protectiveness of human health and the environment. Although there has not yet been a formal decision to adopt the new, more stringent standards for the SSTOU, this report uses the more stringent of either the ROD's Circular WQB-7 [MDHES, 1994] or the current Circular DEQ-7 [DEQ, 2017] standards for evaluating compliance for the COCs.

The most restrictive surface water standard for each COC (arsenic, cadmium, copper, lead, mercury, and zinc) is either the chronic aquatic life standard (ALS) or the human health surface water standard (HHSWS) from either Circular WQB-7 [MDHES, 1994] or Circular DEQ-7 [DEQ, 2017]. In both versions, the chronic ALS is hardness-based for cadmium, copper, lead, and zinc. Thus, the chronic ALS varies in relation to water hardness for those metals, in all cases becoming less restrictive as water hardness increases. The most restrictive surface water standard for each COC is depicted Table 1-1. This report uses the current Circular DEQ-7 [DEQ, 2017] standards as reference values for metals which are not COCs (Table 1-2).

The most current DEQ Circular-7 surface water standards for each metal are identified in Table 1-1. Additionally, the SSTOU ROD specifies that the remedial action objective should "support the growth and propagation of fishes and associated aquatic life…including a self-sustaining population of trout species" provided that upstream contaminant sources are eliminated.

Silver Bow Creek is classified as an "I" stream under the MCA 75-5-301 and associated administrative rules. Designated beneficial uses for I-class streams are "drinking, culinary, and food processing purposes after conventional treatment; bathing, swimming, and recreation; growth and propagation of fishes and associated aquatic life, waterfowl, and furbearers; and agricultural and industrial water supply". I-classified streams include the following criteria for physical properties of water:

- Dissolved oxygen concentration must not be reduced below the applicable standards given in Circular DEQ-7 (i.e., 1-day minimum = 3 mg/L) [DEQ and USEPA, 1995; DEQ, 2017].
- Hydrogen ion concentration (pH) must be maintained within the range of 6.5 to 9.5.
- Except as permitted in MCA 75-5-318, no increase in naturally occurring turbidity is allowed which will or is likely to create a nuisance or render the waters harmful, detrimental, or injurious to public health, recreation, safety, welfare, livestock, wild animals, birds, fish, or other wildlife.

- No increase in naturally occurring temperature is allowed which will or is likely to create a nuisance or render the waters harmful, detrimental, or injurious to public health, recreation, safety, welfare, livestock, wild animals, birds, fish, or other wildlife.
- No increases are allowed above naturally occurring concentrations of sediment or suspended sediment (except as permitted in MCA 75-5-318), and settleable solids, oils, or floating solids, which will or are likely to create a nuisance or render the waters harmful, detrimental, or injurious to public health, recreation, safety, welfare, livestock, wild animals, birds, fish, or other wildlife.

The SSTOU ROD did not specify nutrient (i.e., nitrogen and phosphorus) standards for surface waters in the SSTOU. However, base numeric nutrient standards have been adopted by the Montana Board of Environmental Review and DEQ under rulemaking authority in MCA 75-5-301. Department Circular DEQ-12A [DEQ, 2014] specifies the nutrient standards for wadeable streams in the Middle Rockies Ecoregion, which includes Silver Bow Creek and tributaries in the SSTOU. The following nutrient standards apply to streams in the SSTOU between July 1 and September 30:

- Total phosphorus = 0.03 mg/L,
- Total nitrogen = 0.3 mg/L.

Additonally, Circular DEQ-7 [DEQ, 2017] specifies the following ALS for total ammonia which are applicable year-round[2]:

- Total ammonia acute ALS = 13.3 mg/L,
- Total ammonia chronic ALS = 3.97 mg/L.

In addition to the primary COCs, non-COCs and nutrients, measured surface water parameters included common cations and anions, total suspended sediment and field parameters including streamflow, water temperature, pH, conductivity, and turbidity. These additional data support the interpretation of water quality monitoring results and are needed to assess impairments to beneficial uses.

[2] The total ammonia acute ALS is inversely related to pH and water temperature (i.e., as pH and temperature increases the acute ALS decreases) and is also dependent on whether or not early life stage salmonids are present. The given standard assumes pH of 7.5, temperature of 16 C, and early life stage salmonids are present. Typically, pH in the SSTOU is at least 7.5 and salmonids are known to be present in the SSTOU [RESPEC, 2017a; 2018a]. The chronic ALS for ammonia is not influenced by the presence or absence of early life stage salmonids.

Table 1-1. Comparison of the Montana surface water standards in July 1994 (effective at the time of issuance of the Streamside Tailings Operable Unit Record of Decision) and May 2017 (effective since 2017) for each contaminant of concern.

Contaminant of concern[3]	Chronic aquatic life standard (mg/L)		Human health surface water standard (mg/L)	
	MDHES [1994]	DEQ [2017]	MDHES [1994]	DEQ [2017]
Arsenic	0.190	0.150	0.018	0.010
Cadmium	0.00113	0.00079	0.00500	0.00500
Copper	0.012	0.009	1.000	1.300
Lead[4]	0.0032	0.0032	0.0150	0.0150
Mercury	0.000012	0.000910	0.000140	0.000050
Zinc	0.10599	0.11982	5.00000	2.00000

Gray cells identify the most restrictive standard.

Table 1-2. Montana surface water standards for metals that are not contaminants of concern in the Streamside Tailings Operable Unit [DEQ, 2017].

Metal[5,6]	Aquatic life standard (mg/L)		Human health surface water standard (mg/L)
	Acute	Chronic	
Aluminum	0.750	0.087	-
Antimony	-	-	0.0056
Barium	-	-	1
Beryllium	-	-	0.004
Boron	-	-	-
Chromium	1.803	0.086	0.1
Cobalt	-	-	-
Iron	-	1.00	-
Manganese	-	-	-
Molybdenum	-	-	-
Nickel	0.469	0.052	0.100
Selenium	0.020	0.005	0.050
Silver	0.0041	-	0.1000

[3] The aquatic life standards for cadmium, copper, lead, and zinc vary in relation to water hardness. The values displayed in this table correspond to a water hardness of 100 mg/L as $CaCO_3$.

[4] The chronic aquatic life standard is most restrictive for lead until hardness exceeds 338 mg/L as $CaCO_3$. At hardness more than 338 mg/L as $CaCO_3$, the human health surface water standard becomes more restrictive. Lead standards were the same in MDHES [1994] and DEQ [2017].

[5] The aquatic life standards for chromium, nickel and silver vary in relation to water hardness. The values displayed in this table correspond to a water hardness of 100 mg/L as $CaCO_3$.

[6] The aquatic life standards in this table are based on total recoverable concentrations for all metals in this table except aluminum which is based on dissolved concentrations.

Metal[5,6]	Aquatic life standard (mg/L)		Human health surface water standard (mg/L)
	Acute	Chronic	
Uranium	-	-	0.03
Vanadium	-	-	-

Gray cells identify the most restrictive standard.

1.3 METHODS

The purpose of the surface water monitoring program is to collect data describing the temporal and spatial variation of metal and nutrient concentrations, and other physical properties of surface water in the SSTOU. These data provide a long-term record of environmental conditions in the SSTOU. As of 2018, 19 years of SSTOU surface water data (2000-2018) have been collected under this monitoring program. This long-term record provides a dataset to evaluate the effect of remediation on environmental conditions in the SSTOU over time.

An overview of surface water monitoring methods is provided here, and more detail can be found in the project sampling and analysis plan (SAP) [RESPEC, 2018b]. Changes to the surface water monitoring program have occurred over time and a record of these changes is provided in the SAP [RESPEC, 2018b]. The program attempts to adhere to monitoring requirements specified in the SSTOU ROD (Table 1-3). To comply with these requirements, surface water sampling sites were added to the monitoring network in 2013 (Sites SS-13 and SS-16B) and 2014 (Site SS-19) (Figure 1-2; Table 1-4). All of the sites required by the SSTOU ROD (Table 1-3) have been included in the surface water monitoring program since 2014.

Table 1-3. Minimum post-remedy monitoring requirements for surface water monitoring as Specified in the Record of Decision for the Streamside Tailings Operable Unit [DEQ and USEPA, 1995].

Locations	Analytical Parameters	Analytes
SS-07, SS-10, SS-13, SS-14, SS-15, SS-16B, SS-17, SS-19	Metals (total recoverable and dissolved)	Arsenic, cadmium, copper, lead, mercury, zinc
	Common ions	Calcium, magnesium, sodium, potassium, chloride, sulfate
	Nutrients	Nitrate plus nitrite nitrogen, phosphorus
	Physical properties	Temperature, acidity (pH), oxidation-reduction potential (Eh), conductance, dissolved oxygen concentration

1.3.1 Monitoring Locations

In 2018, major remediation in the SSTOU was completed in all subareas. Minor remedial actions were in progress in portions of Subarea 2 (Figure 1-2). Monitoring occurred at 16 sites, 12 of which were located within the SSTOU. Locations of some sampling sites were selected based

on SSTOU ROD requirements (Table 1-3). Other sites were selected to provide greater spatial resolution or to assess the influence of specific surface water inputs. Sites located outside the SSTOU were sampled to describe surface water conditions in the stream immediately upstream from the SSTOU (Sites SS-01, SS-05A, and SS-06G) or in a major tributary (German Gulch; Site SS-15G) entering Silver Bow Creek within the SSTOU (Figure 1-2).

Monitoring at Site SS-10B (Silver Bow Creek below Sand Creek) was discontinued in 2017. Site SS-10B had been sampled along with a paired site (Site SS-10A; Silver Bow Creek above Sand Creek) to elicit water chemistry contributions from Sand Creek. However, since 2010, Site SS-10B showed no significant differences in constituent concentrations from Site SS-10A and was providing no additional insight to understanding of contaminant sources in the SSTOU.

* Not located within the Streamside Tailings Operable Unit.

1.3.2 Monitoring Schedule

Monitoring events were scheduled quarterly to describe seasonal variation in water chemistry within the SSTOU. One monitoring event occurred during each calendar quarter. Quarterly monitoring events occurred near the end of each quarter. First quarter (Q1) monitoring occurred from March 21–22 prior to spring snowmelt runoff. Second quarter (Q2) monitoring occurred from June 6-7 near the peak of the spring snowmelt runoff period. Third quarter (Q3) monitoring occurred from September 12-13 during low streamflow conditions. Fourth quarter (Q4) monitoring occurred from November 28-29 during late fall.

1.3.3 Monitoring Parameters

Streamflows were measured at all surface water sampling sites at the time when sampling occurred or were determined from USGS streamflow gages that were co-located with the sampling sites at two sites. All USGS streamflow data included in this report may be "provisional" because at the time this report was completed "approved" USGS data may not have been available. At

[7] Co-located with USGS streamflow gage 12323250.

[8] Co-located with USGS streamflow gage 12323600.

sites without co-located USGS gage stations, streamflows were measured manually. Laboratory analysis of analyte concentrations in samples was provided by Energy Laboratories (Helena, Montana). Water samples were analyzed for metal concentrations, nutrient concentrations, and other chemical and physical properties (Table 1-5).

Table 1-5. Sampling parameters and analytes for surface water monitoring of the Streamside Tailings Operable Unit.

Parameter	Analytes
Concentrations of metal contaminants of concern (total recoverable and dissolved)	Arsenic, cadmium, copper, lead, mercury, zinc
Concentrations of other metals (total recoverable and dissolved)	Aluminum, antimony, barium, beryllium, boron, cobalt, chromium, iron, manganese, molybdenum, nickel, selenium, silver, uranium, vanadium
Nutrient concentrations	Nitrogen (total nitrogen, nitrate plus nitrite, ammonia), phosphorus (total)
Common ion concentrations	Sulfate, total alkalinity, bicarbonate alkalinity, calcium, magnesium, sodium, potassium, chloride, and sulfate
Other physical properties	Total suspended sediment concentration, water hardness, water temperature, pH, specific conductivity, dissolved oxygen (DO), turbidity

1.3.4 Sample Collection and Analysis

Sample collection, analysis, and quality assurance procedures are described in the program sampling and analysis plan [RESPEC, 2018b] and quality assurance project plan [RESPEC, 2014]. Methods generally followed standard operating procedures (SOPs) developed for the Clark Fork River [AR, 1992]. Field sampling procedures were in accordance with DEQ [2012a] and followed "clean hands/dirty hands" procedures as described in USGS [2006][9]. Composited surface water samples were collected using width- and depth-integration according to methods described in USGS [2006]. Field parameters (water temperature, pH, dissolved oxygen concentration, and conductivity) were measured during each monitoring event with a field multimeter (YSI Professional Plus or YSI 556). Turbidity was measured with a field turbidity meter (Hach Model 2100P Portable Turbidimeter). Streamflows were measured using a portable electromagnetic streamflow meter (Marsh-McBirney Flo-Mate 2000). Calibration methods for field meters, data recording and handling methods, and quality assurance and quality control procedures are described in the program sampling and analysis plan [RESPEC, 2018b]. Samples were analyzed

[9] We deviated from the USGS [2006] protocols to minimize sample contamination [described in Section 4.0.2 of USGS, 2006] in two regards. First, we did not collect samples sequentially in the order of least to greatest potential for contamination. Second, samples were processed outside sampling vehicles, rather than within an enclosed space. Also note that we did not follow all "clean hands/dirty hands" protocols of Method 1669 [USEPA, 1996] or the low-level (i.e., part-per-trillion) protocols of the USGS [Lewis and Brigham, 2004].

by Energy Laboratories (Helena, Montana). Laboratory analysis procedures for each analyte are presented in Table 1-6.

Table 1-6. Analytes, analytical methods, and reporting limits for surface water samples in the Streamside Tailings Operable Unit.

Analyte	Requested Method	Requested Reporting Limit (mg/L)[10]	Holding Time (days)	Bottle	Preservative
Water Samples - Physical Properties and Inorganics					
Solids, Total Suspended (at 105 C)	A 2540 D	1	7	1 L HDPE

1.3.5 Data Analysis

This report primarily presents a summary of surface water data collected in the SSTOU monitoring program in 2018. For certain important constituents (e.g., nutrient concentrations and COC concentrations), longer-term results are presented to place 2018 results in context with prior annual monitoring data.

Data analysis includes description of spatial trends (among sample sites during the same sample period) and temporal (quarterly and annual) trends in constituent concentrations. Data in the spatial graphs are presented longitudinally from upstream to downstream with symbols representing each sample event (e.g. Q1, Q2, Q3, Q4). Symbols are connected with a solid line for Silver Bow Creek mainstem sites with the exception of the sites above and below German Gulch (SS-15A and SS15B); these sites are connected with a dashed line to help distinguish the influence of the German Gulch tributary (SS-15G), For constituents of primary interest (e.g., total recoverable COC concentrations), longer-term (since 2010) temporal graphs are included to provide context for the recent results and to evaluate variability in concentrations through time.

In addition, for COCs with performance goal targets, or for constituents which have state-specified standards, sample concentrations are compared to those standards to evaluate exceedances. Evaluation of some ALS standards requires an assumption that the measured analyte concentrations are consistent over time. For example, the chronic ALS is typically based on 96-hour mean concentrations and the acute ALSs are typically based on 1-hour mean concentrations [DEQ, 2017]. However, in this monitoring program, analyte concentrations are measured at a specific point in time and mean concentrations over time are unknown. Therefore, all assessments of ALS exceedances assume that the measured concentration was representative of the mean concentration over the necessary time period.

Surface water samples were analyzed for COC and non-COC metal and metalloid concentrations. The SSTOU ROD specifies that monitoring should assess if non-COC metals have concentrations exceeding performance goals [DEQ and USEPA, 1995]. We have interpreted the performance goals for non-COC analytes to be the most restrictive of the most current Circular DEQ-7 standards [DEQ, 2017].

1.3.6 Data Validation

Data quality objectives were established in the SSTOU quality assurance project plan (QAPP) for data representativeness, comparability, completeness, sensitivity, precision, bias, and accuracy [RESPEC, 2014]. Methods for field and laboratory quality assurance and quality control procedures are described in detail in the QAPP. A completed quality assurance and quality control checklist, summary tables of field duplicate and field blank results, and assessments of data quality objectives are included in Appendix A.

1.4 RESULTS

1.4.1 Streamflow

In comparison to the long-term median for the period of record at each site monitored by the U.S. Geological Survey, streamflows in 2018 for Silver Bow Creek and Blacktail Creek were well above average from late March through the remainder of the year (Figure 1-3; Figure 1-4; Figure 1-5). Streamflows during spring runoff were substantially higher than normal and the duration of the runoff was far longer than normal in Silver Bow Creek and Blacktail Creek (Figure 1-3; Figure 1-4; Figure 1-5). Due to the strong, prolonged runoff, summer and fall streamflows were also well above normal (Figure 1-3; Figure 1-4; Figure 1-5).

Longitudinally (i.e., from upstream to downstream sites) streamflows generally increased gradually between Blacktail Creek at Father Sheehan Park (Site SS-01) and Silver Bow Creek at Frontage Road (Site SS-19) (Figure 1-6). During Q2, streamflows increased more rapidly downstream from Browns Gulch (between Sites SS-11C and SS-11D) (Figure 1-6). Downstream from German Gulch, more pronounced streamflow increases in Q1 and Q2 could not be discerned directly from the data because measurements were not made due to hazardous high water or ice.

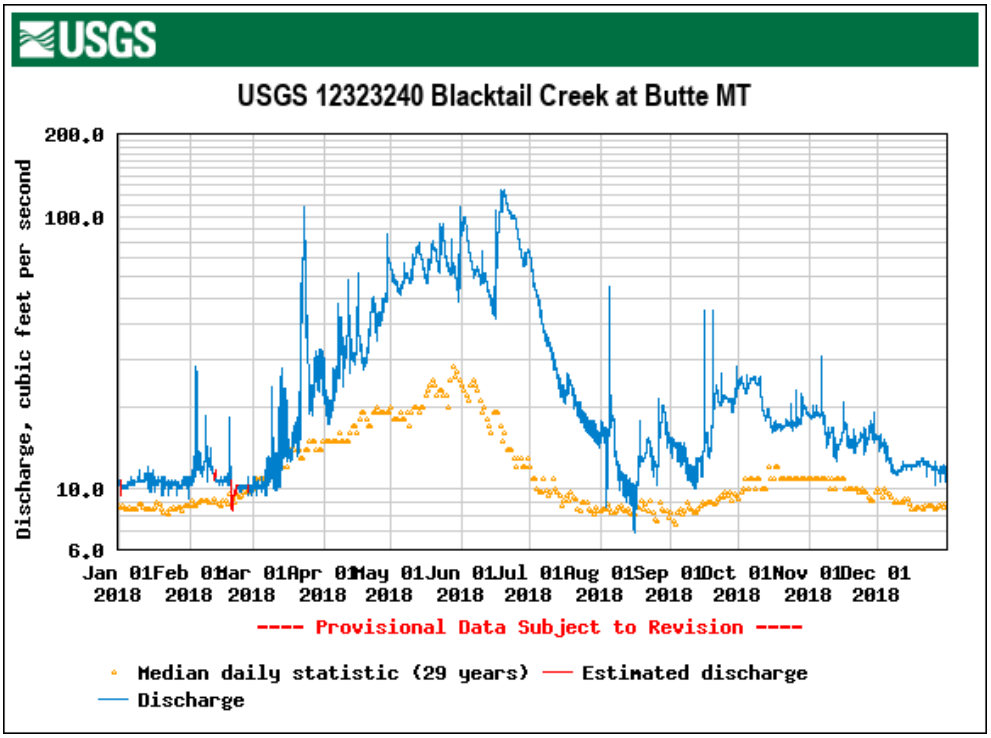

Figure 1-3. Annual hydrograph for Blacktail Creek at Butte, 2018.

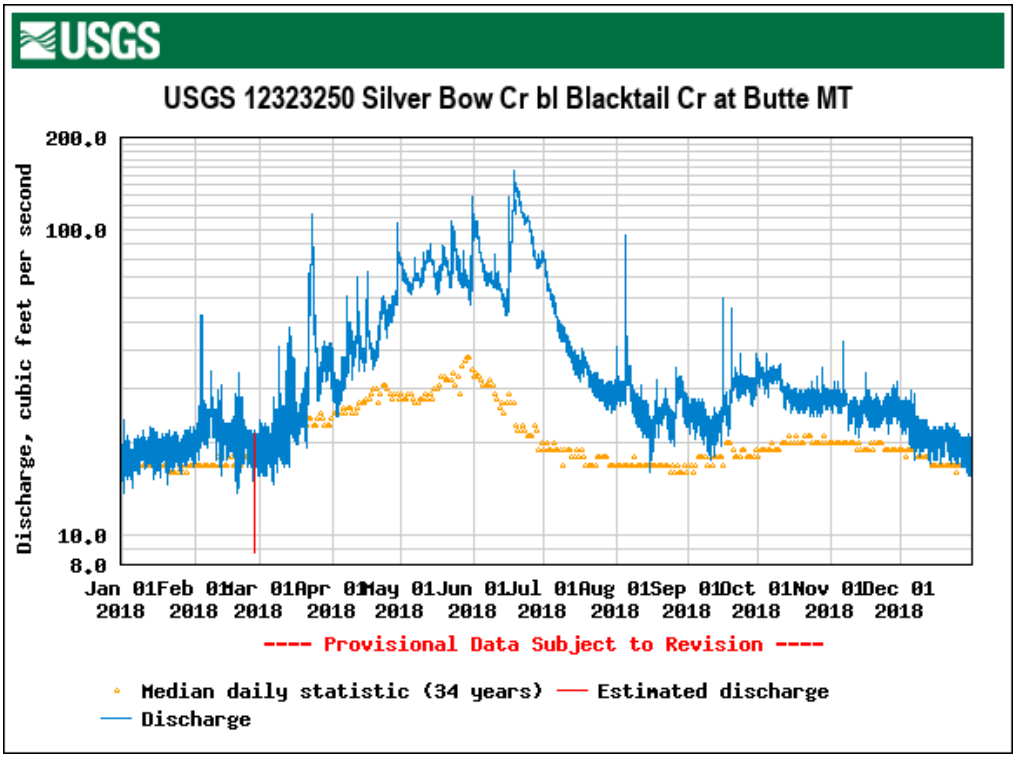

Figure 1-4. Annual hydrograph for Silver Bow Creek below Blacktail Creek at Butte, 2018.

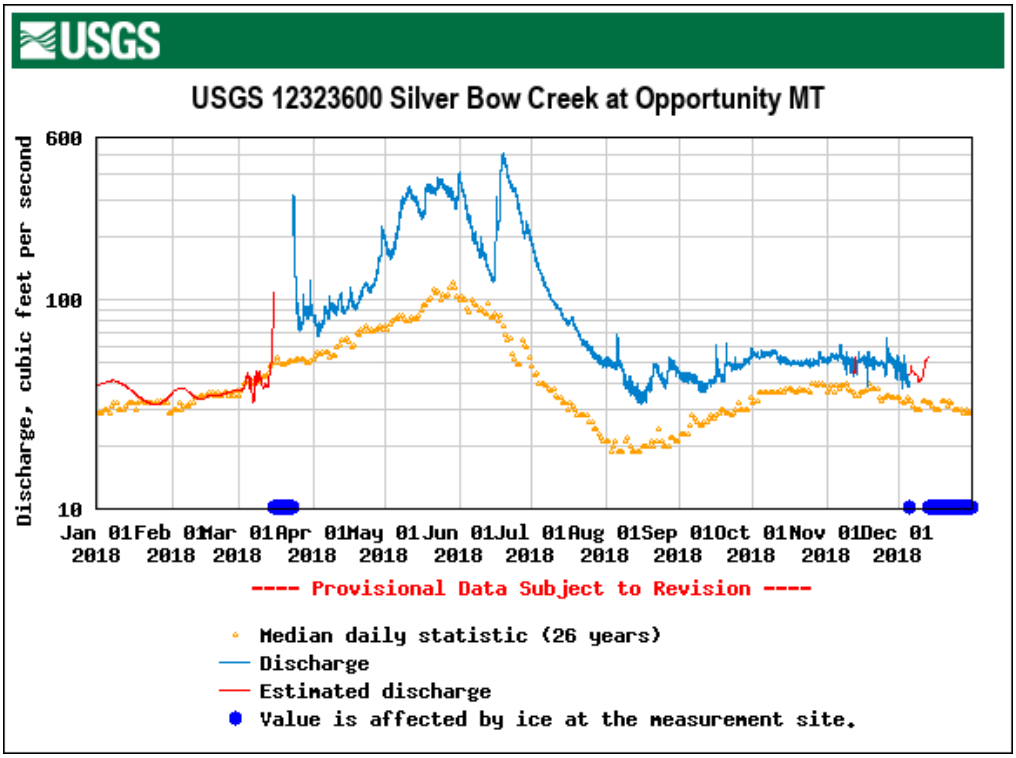

Figure 1-5. Annual hydrograph for Silver Bow Creek at Opportunity, 2018.

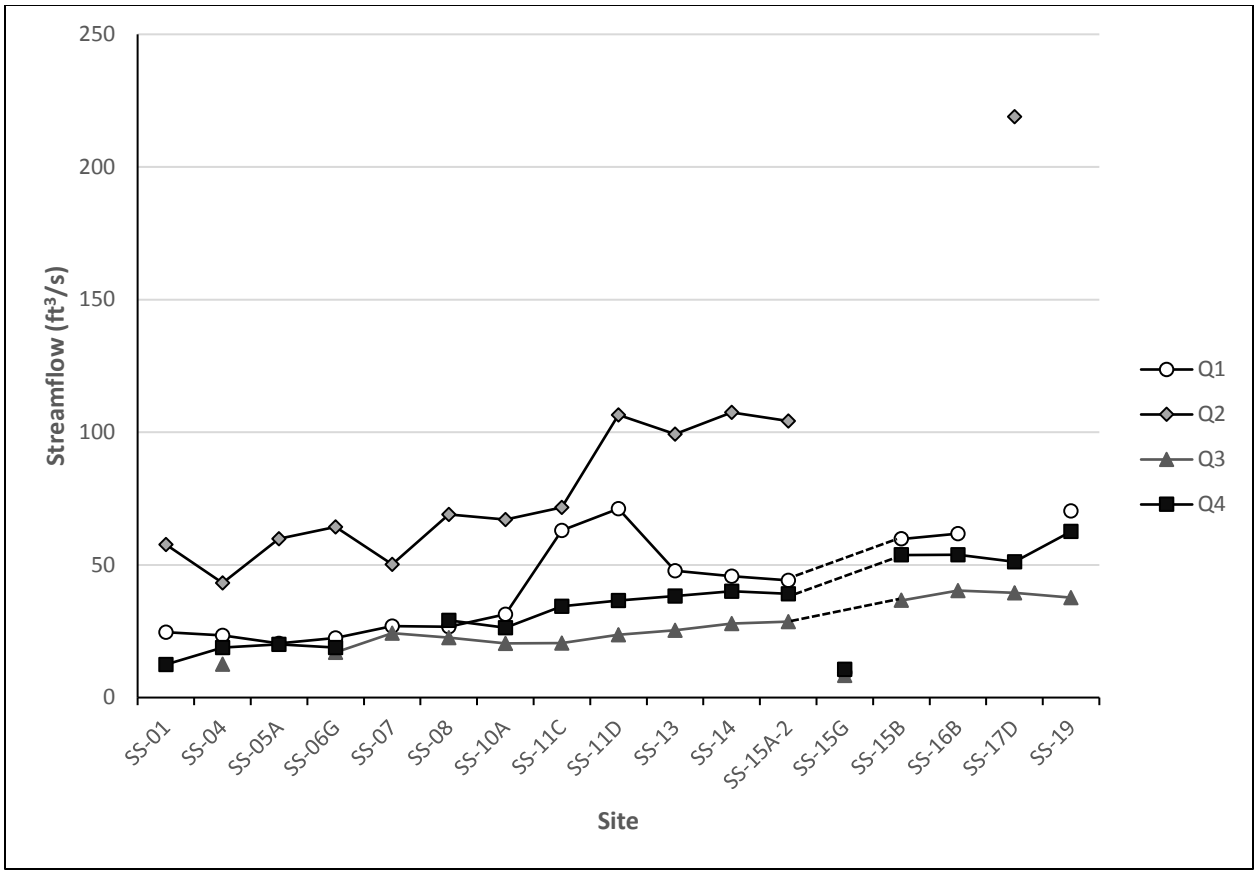

Figure 1-6. Streamflows at Streamside Tailings Operable Unit sample sites, 2018.[11]

[11] All streamflow measurements from SS-04, SS-07, and SS-17D are provisional data from U.S. Geological Survey [USGS, 2019]. Streamflows were not measure in Q3 at SS-01 and SS-05A due to instrument failure. Streamflows were not measured in Q2 at SS-15G, SS-15B, SS-16B, or SS-19 due to hazardous conditions related to high water.

1.4.2 Field Parameters

1.4.2.1 Water Temperature

Water temperatures in the SSTOU in 2018 were as expected for each quarterly monitoring event. Quarterly temperature ranges were: 0.4-7.0 degrees Celsius (C; Q1), 8.5-17.7 C (Q2), 9.5-14.7 C (Q3), and 1.5-6.4 C (Q4) (Figure 1-7).

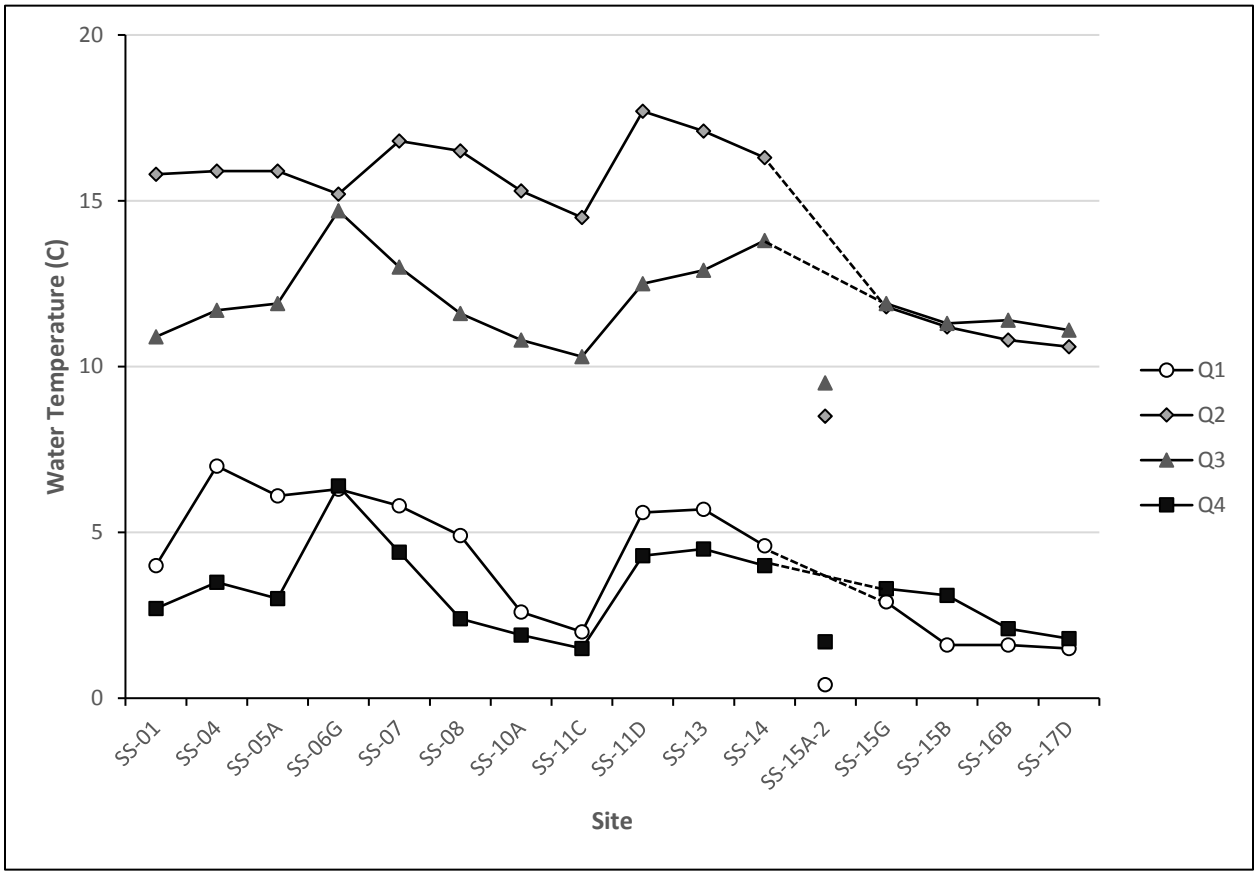

Figure 1-7. Water temperatures at Streamside Tailings Operable Unit sample sites, 2018.

1.4.2.2 pH

All pH measurements in the SSTOU in 2018 were within the range designated for beneficial uses of I-class streams (6.5-9.5). Quarterly pH ranges were: 7.4-8.4 (Q1), 7.2-7.9 (Q2), 7.5-8.8 (Q3), and 7.1-8.0 (Q4) (Figure 1-8).

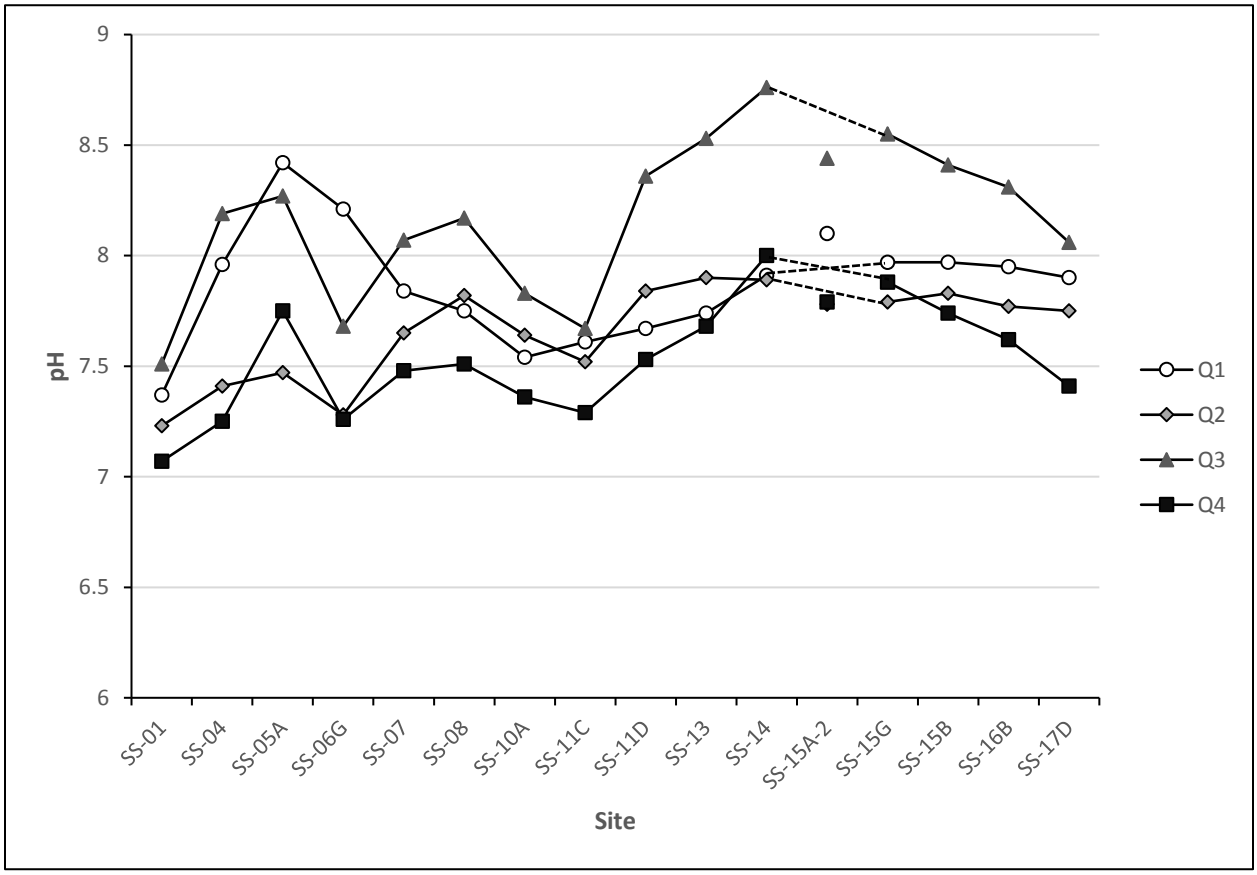

Figure 1-8. Surface water pH at Streamside Tailings Operable Unit sample sites, 2018.

1.4.2.3 Conductivity

Conductivity in the SSTOU in 2018 varied by sample period but demonstrated consistent longitudinal patterns. Conductivity was relatively high in Q1 and Q3 and low in Q2 (Figure 1-9). Generally, conductivity in Blacktail Creek and Silver Bow Creek increased rapidly between Father Sheehan Park (Site SS-01) and the Butte WWTP (Site SS-06G), and then remained relatively steady between Site SS-07 downstream to Frontage Road (Site SS-19) (Figure 1-9). The German Gulch input, which had low (no more than 227 microsiemens per centimeter [µS/cm]) conductivity during all quarters, slightly reduced conductivity in the mainstem at downstream sites during all quarters (Figure 1-9). In addition, there was variability in conductivity at several Subarea 2 Silver Bow Creek sites from Sand Creek to Miles Crossing (i.e., Sites SS-10A, SS-11C, SS-11D, SS-13, and SS-14). Quarterly conductivity ranges were: 197-543 µS/cm (Q1), 153-363 µS/cm (Q2), and 150-619 µS/cm (Q3) (Figure 1-9). Conductivity was not measured in Q4 due to instrument failure.

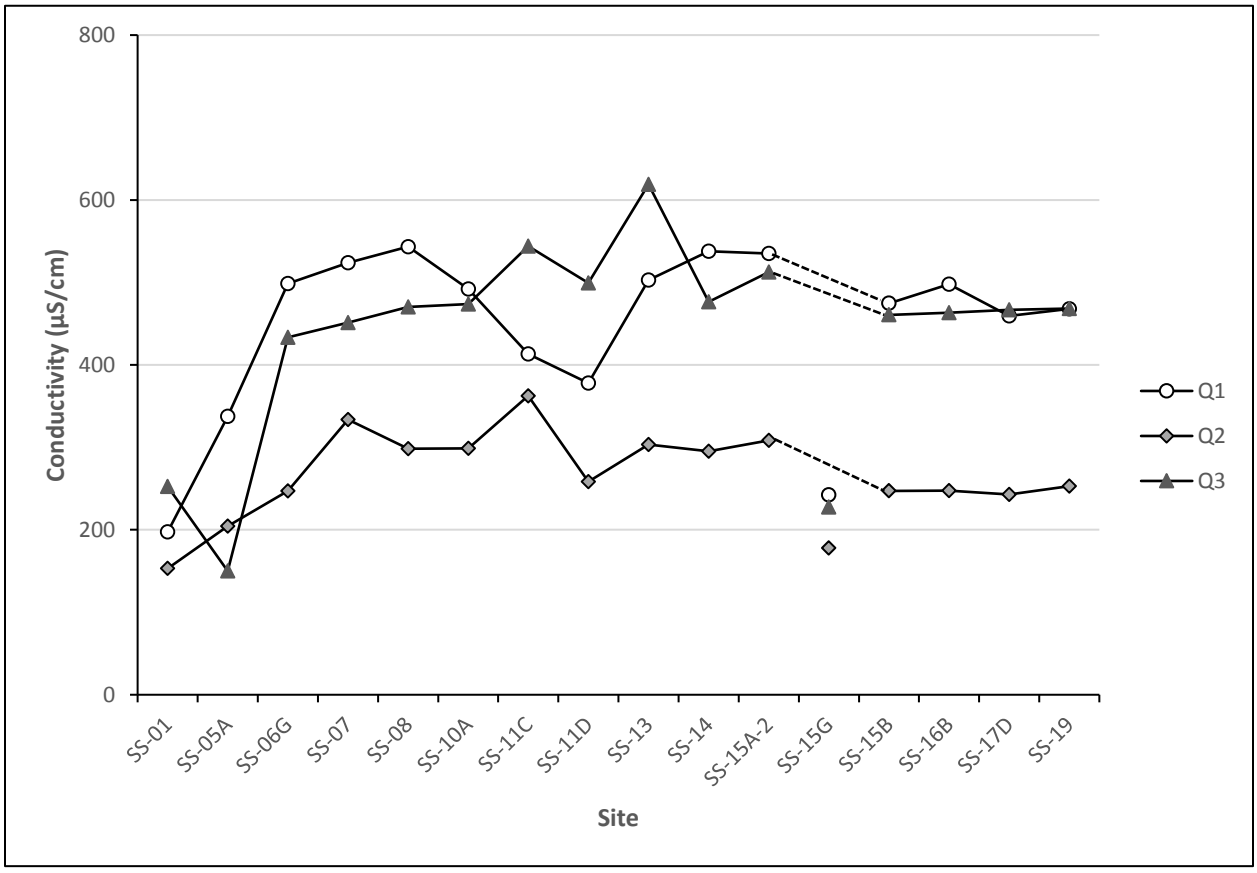

Figure 1-9. Conductivity at Streamside Tailings Operable Unit sample sites, 2018.

1.4.2.4 Dissolved Oxygen

All measured dissolved oxygen concentrations in the SSTOU in 2018 were above the applicable standards (i.e., 1-day minimum = 3 milligrams per liter [mg/L]) [DEQ and USEPA, 1995; DEQ, 2017]. The minimum dissolved oxygen concentration measured in 2018 was 7.8 mg/L (Figure 1-10).

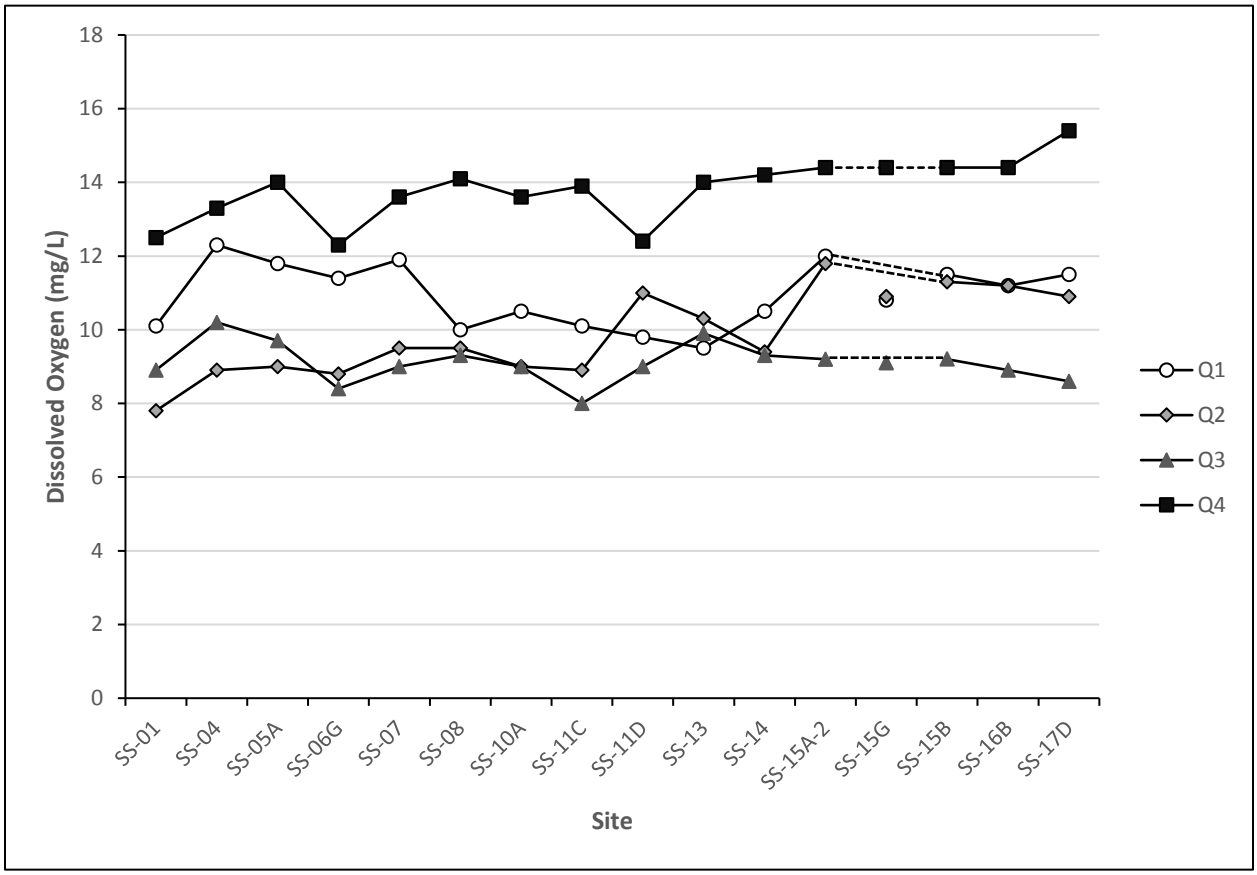

Figure 1-10. Dissolved oxygen concentrations at Streamside Tailings Operable Unit sample sites, 2018.

1.4.2.5 Turbidity

Turbidity was low to moderate (less than 24 Nephelometric Turbidity Units [NTU]) throughout the SSTOU in 2018 with the exception of Blacktail Creek at Father Sheehan Park (Site SS-01) in Q1 (Figure 1-11). Site SS-01 had high substantially higher turbidity (78 NTU) than any other site in 2018 which had turbidity less than 25 NTU (Figure 1-11). Site SS-01 also had particularly high turbidity in Q1 2017 [RESPEC, 2018a]. Turbidity was higher at most sites in Q1 and Q2 compared to Q3 and Q4 (Figure 1-11).

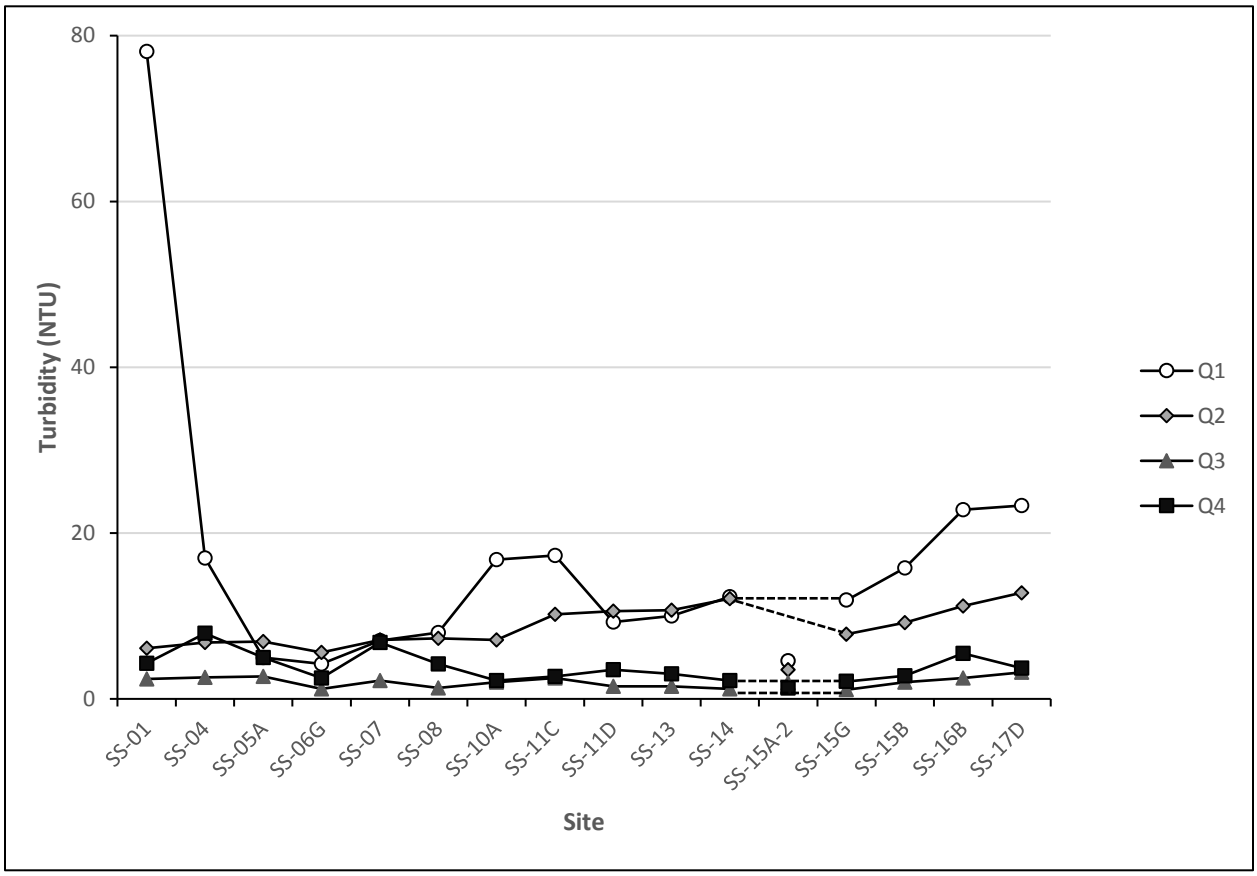

Figure 1-11. Turbidity at Streamside Tailings Operable Unit sample sites, 2018.

1.4.3 Total Suspended Sediment

Seasonal and spatial patterns for total suspended sediment concentrations were similar to turbidity patterns (Figure 1-11; Figure 1-12). As with turbidity, Q1 and Q2 total suspended sediment concentrations were elevated. In addition, concentrations were elevated at Site SS-16B in Q2.

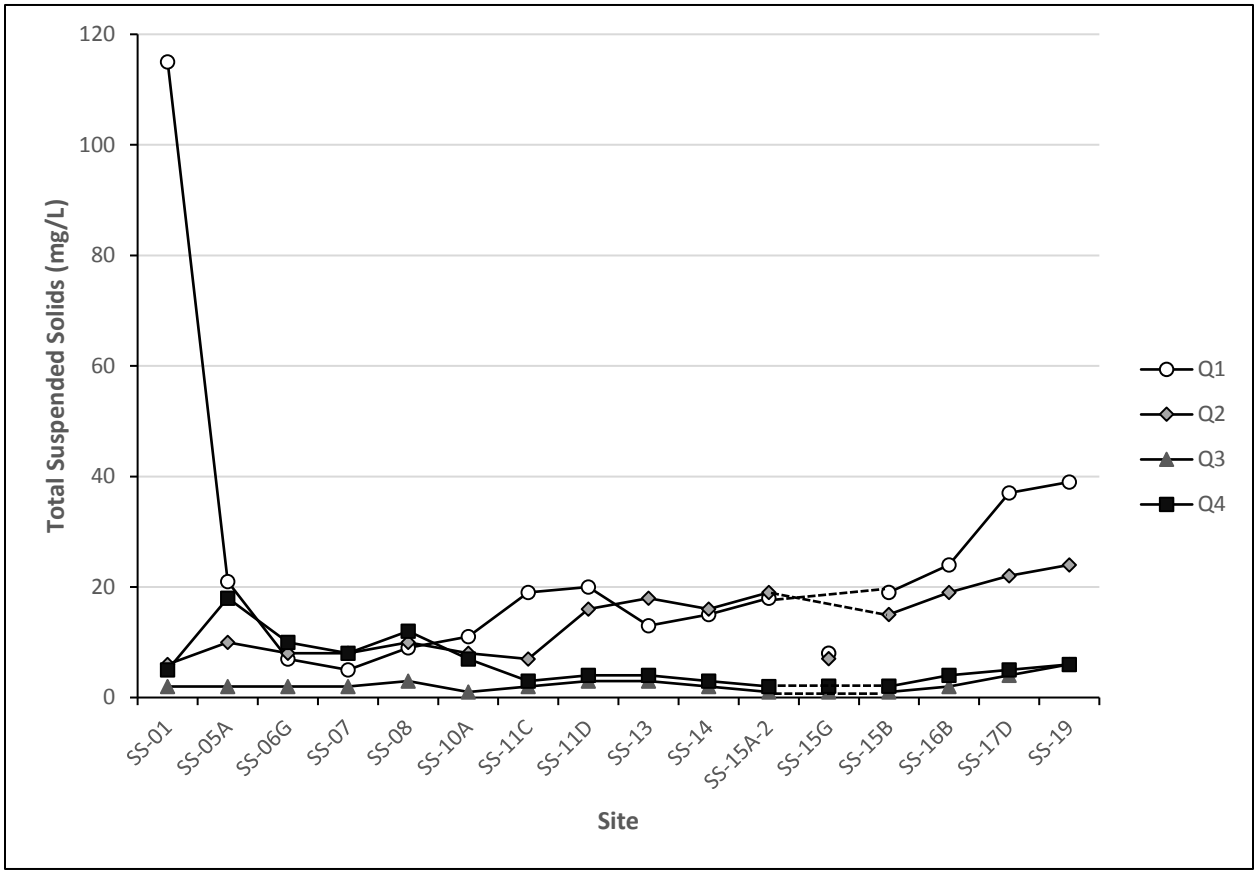

Figure 1-12. Total suspended sediment concentrations at Streamside Tailings Operable Unit sample sites, 2018.

1.4.4 Common Ions

Common ion concentrations were variable among sites but generally demonstrated consistent seasonal patterns. At each site, common ion concentrations were generally lowest during Q2 and highest in Q3 or Q4 (Figure 1-13; Figure 1-14; Figure 1-15; Figure 1-16; Figure 1-17; Figure 1-18; Figure 1-19; Figure 1-20; Figure 1-21). Most ion concentrations were lowest in Blacktail Creek at Father Sheehan Park (Site SS-01) or German Gulch (Site SS-15G) and highest at or near Silver Bow Creek above German Gulch (Site SS-15A-2).

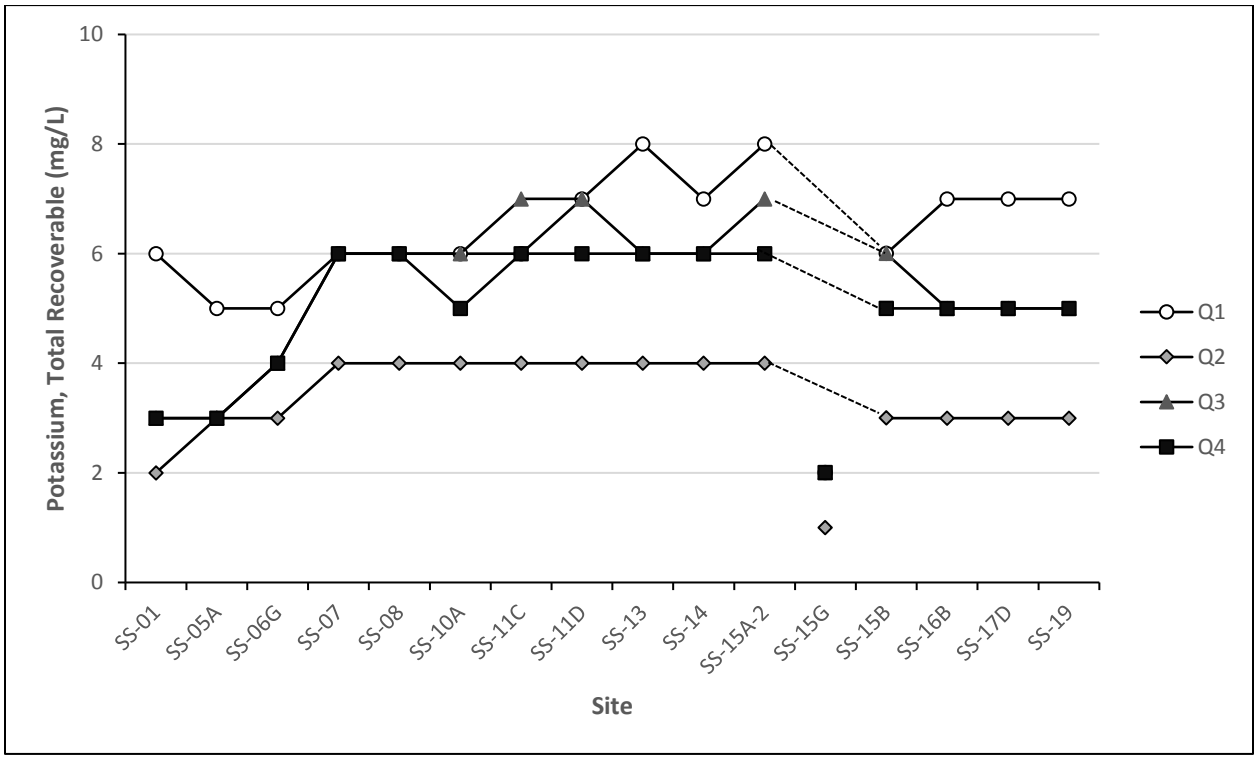

Figure 1-21. Potassium concentrations at Streamside Tailings Operable Unit sample sites, 2018.

1.4.5 Nutrients

1.4.5.1 Total Nitrogen

Total nitrogen concentrations were very high in the SSTOU in 2018 at all sites except German Gulch (Site SS-15G) (Figure 1-22). In Q3, when the total nitrogen standard is applicable, all sites except Site SS-15G (German Gulch) exceeded the 0.3 mg/L total nitrogen standard (Table 1-7; Figure 1-22). Seasonally, concentrations were lowest during spring runoff (Q2) at all sites (Figure 1-22).

Although total nitrogen concentrations remain elevated relative to the total nitrogen standard (Figure 1-22), concentrations have decreased steadily since 2014 particularly at sites immediately downstream from the WWTP (i.e., Sites SS-07, SS-08, and SS-10A) (Figure 1-23).

As in prior monitoring years, total nitrogen concentrations increased from above (Site SS-06G) to below (Site SS-07) the WWTP during each sampling event in 2018 but the increase was relatively low compared to prior monitoring years (particularly prior to 2016). In 2018, concentrations increased by 233 percent in Q1, 131 percent in Q2, 128 percent in Q3, and 135 percent in Q4 (Table 1-7). Similarly, in Q1 2017 the increase in concentrations between these sites was 248 percent but less than 140 percent during the other three quarters [RESPEC, 2018a].

Table 1-7. Total nitrogen concentrations (mg/L) at Streamside Tailings Operable Unit monitoring stations, 2018.

Site ID	Site Location	Sample Quarter

SS-19	Silver Bow Creek at Frontage Road	1.92[D]	0.43	0.84	0.99

D Result obtained from analysis of diluted sample.

Exceeds the 0.3 mg/L summertime base total nitrogen standard [DEQ, 2014].

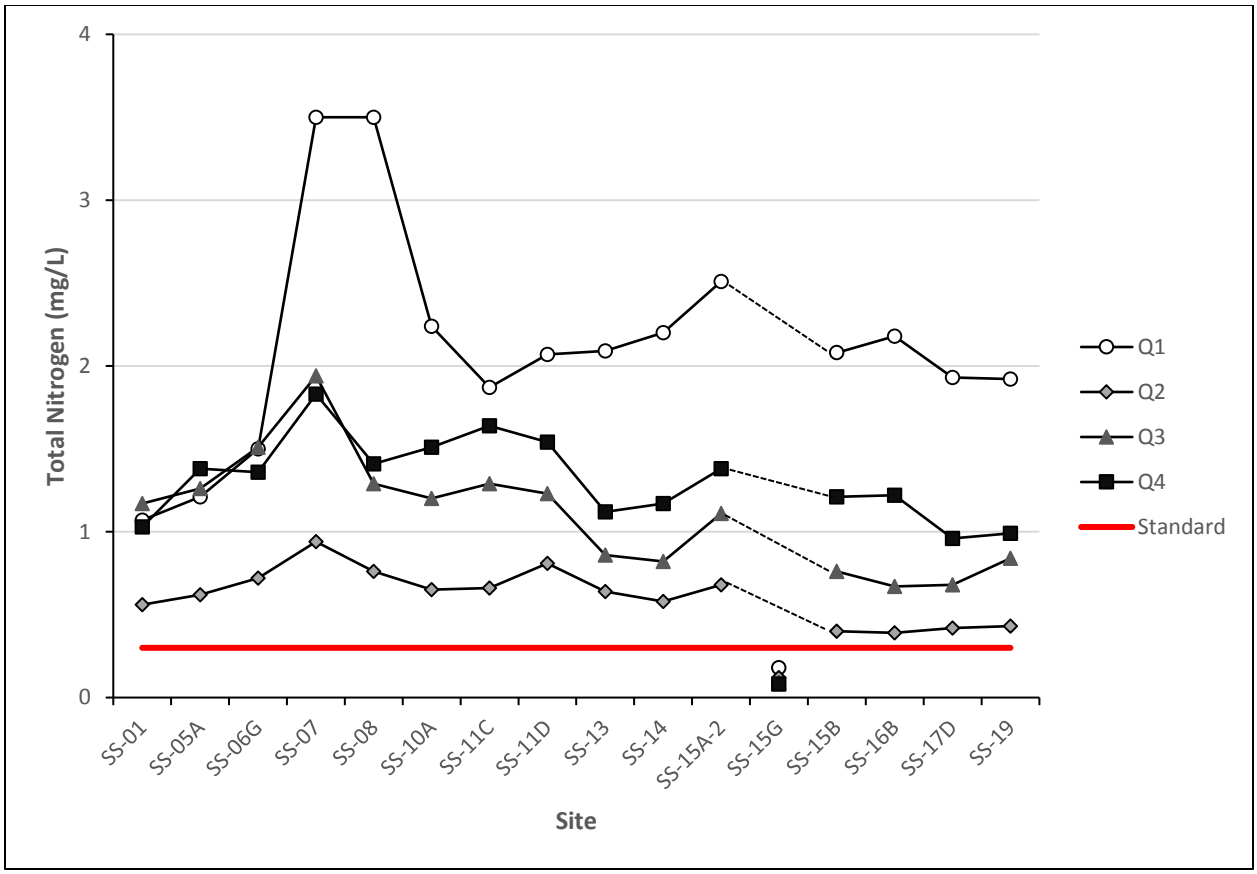

Figure 1-22. Total nitrogen concentrations at Streamside Tailings Operable Unit monitoring stations, 2018. Red line represents the total nitrogen standard [DEQ, 2014].

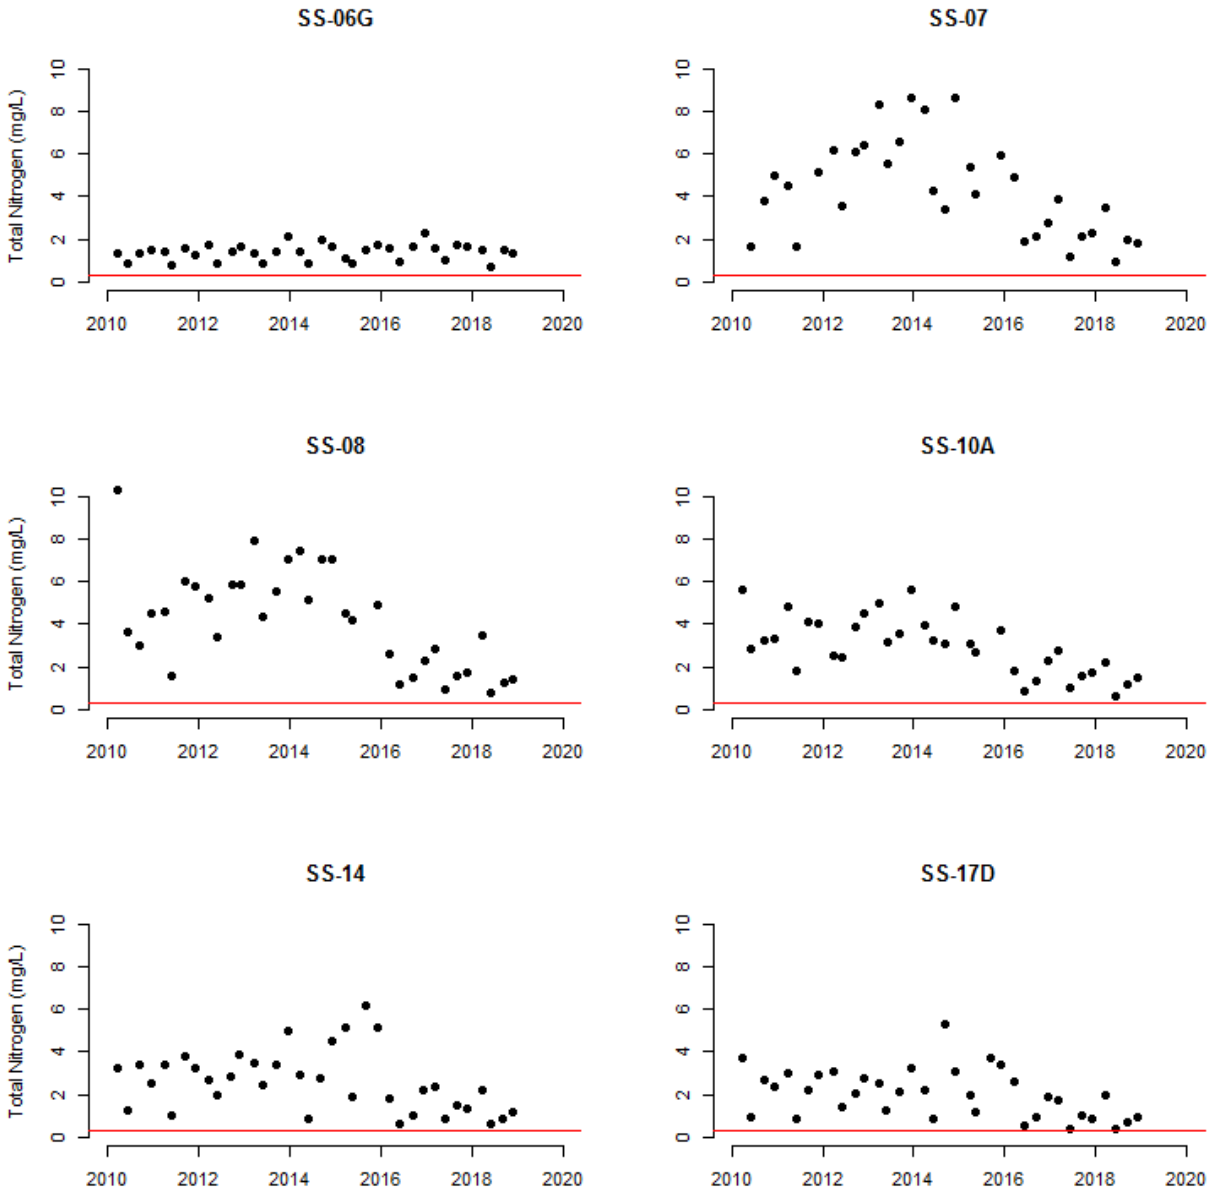

Figure 1-23. Total nitrogen concentrations (mg/L) at selected Silver Bow Creek sites in the Streamside Tailings Operable Unit: above Butte WWTP (Site SS-06G), below Butte WWTP (Site SS-07), at Rocker (Site SS-08), above Sand Creek (Site SS-10A), at Miles Crossing (Site SS-14), and at Opportunity (Site SS-17D). Red line represents the total nitrogen standard [DEQ, 2014].[12]

[12] Several samples with very high total nitrogen concentrations are not depicted: on September 9, 2015, 32.9 mg/L at Site SS-07, 24.9 mg/L at Site SS-08, and 18.8 mg/L at Site SS-10A; on March 23, 2010, 16.5 mg/L at Site SS-07; and on September 8, 2011, 11.0 mg/L at Site SS-07.

1.4.5.2 Nitrate plus Nitrite Nitrogen

Nitrate plus nitrite nitrogen concentrations were high (more than 0.5 mg/L) in 2018 at all sites with the exception of German Gulch (Site SS-15G) (Table 1-8). Seasonally, concentrations were lowest in Q2 and similar in other quarters with some variation among sites (Figure 1-25). During all quarters, concentrations increased steadily from Blacktail Creek at Father Sheehan Park (Site SS-01) to Silver Bow Creek below the Butte WWTP (Site SS-07), and then generally decreased (but with local deviations) downstream to Frontage Road (Site SS-19; Figure 1-24). Concentrations in German Gulch were much lower than in any Blacktail Creek or Silver Bow Creek sites (Table 1-8). Concentrations in 2018 at several long-term monitoring sites below the WWTP appeared to exhibit a declining trend although the concentrations have been variable and therefore those trends cannot be discerned with a high degree of confidence (Figure 1-25).

Table 1-8. Nitrate plus nitrite nitrogen concentrations (mg/L) at Streamside Tailings Operable Unit monitoring stations, 2018.

ND Not detected at analytical method detection limit.

J Estimated result either because sample result was below analytical reporting limit or because the associated field sample and duplicate pair had a relative percent difference greater than 25 percent.

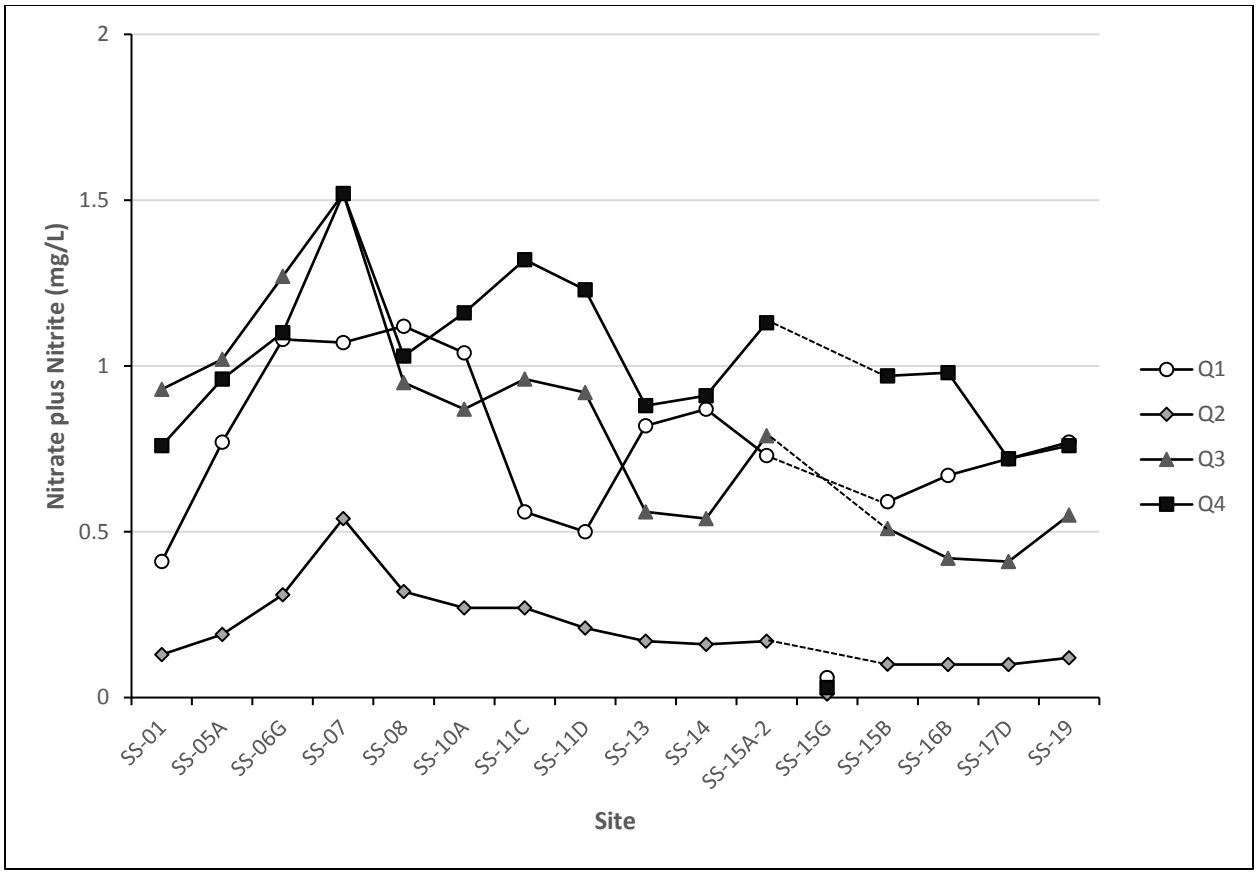

Figure 1-24. Nitrate plus nitrite nitrogen concentrations at Streamside Tailings Operable Unit monitoring stations, 2018.

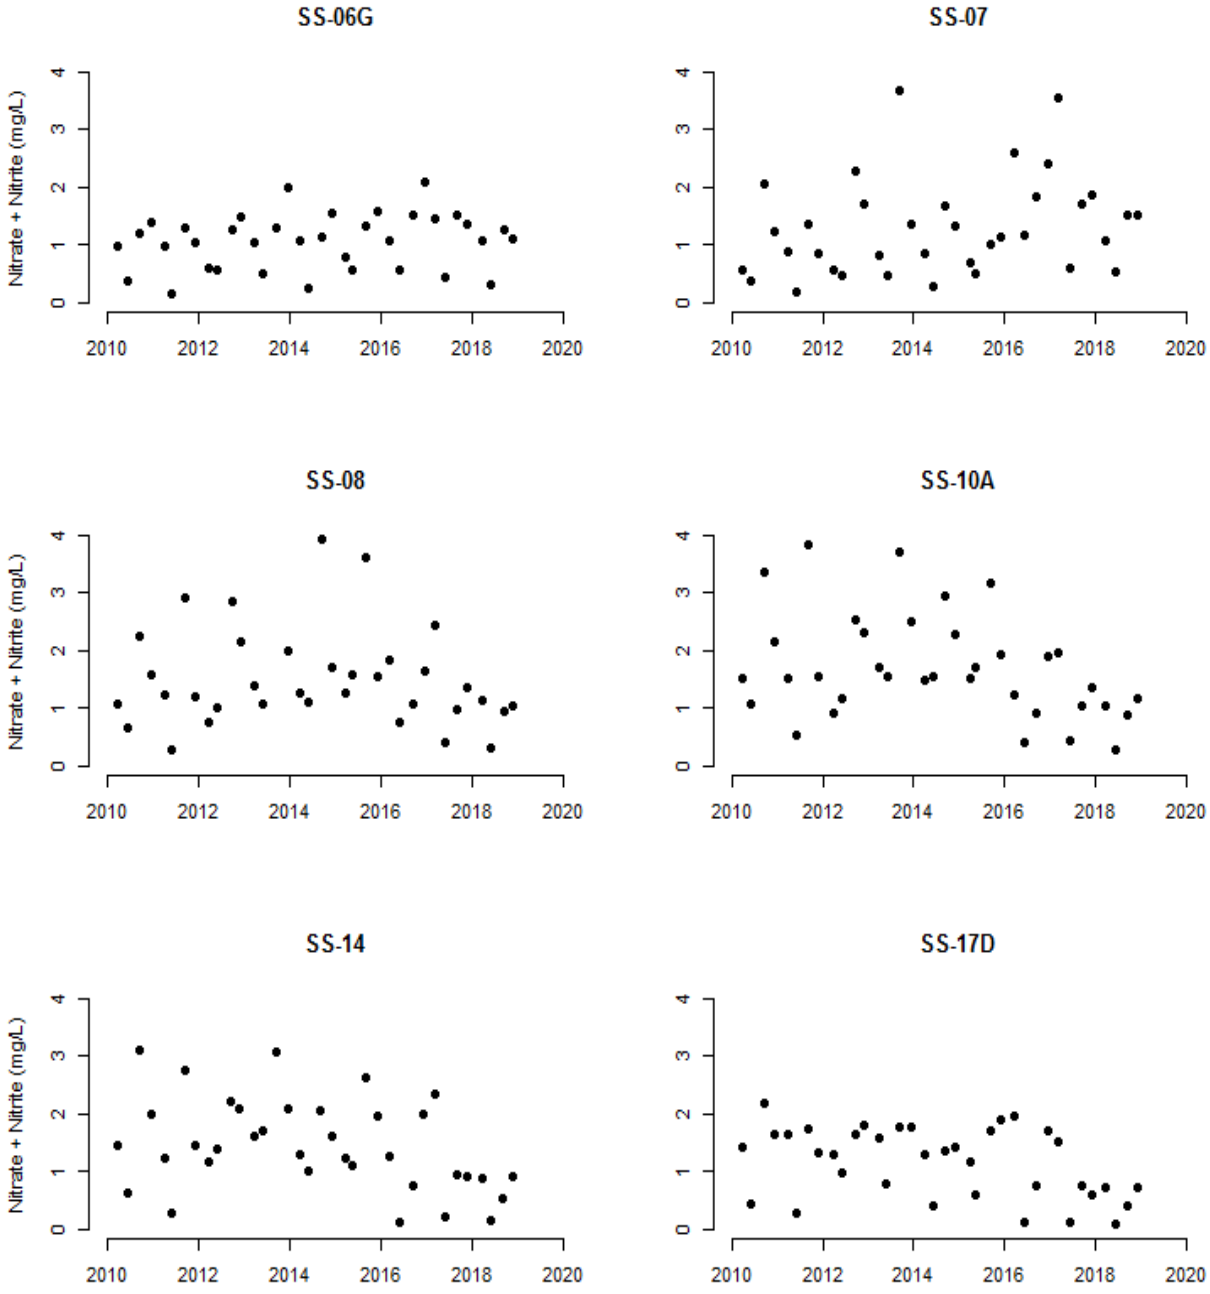

Figure 1-25. Nitrate plus nitrite concentrations (mg/L) at selected Silver Bow Creek sites in the Streamside Tailings Operable Unit: above Butte WWTP (Site SS-06G), below Butte WWTP (Site SS-07), at Rocker (Site SS-08), above Sand Creek (Site SS-10A), at Miles Crossing (Site SS-14), and at Opportunity (Site SS-17D).[13]

[13] One sample from Site SS-08 on September 12, 2013 (5.24 mg/L) is not depicted.

1.4.5.3 Total Ammonia

In all samples collected in Q2, Q3, and Q4 of 2018, ammonia concentrations were below the method detection limit or analytical reporting limit (Table 1-9) In Q1 however, concentrations increased rapidly from above (Site SS-06G) to below the WWTP (Site SS-07), then declined sharply downstream to above Sand Creek (Site SS-10A) and stabilized (with some variation) downstream to Frontage Road (Site SS-19) (Figure 1-26).

Upgrades to the Butte WWTP, which occurred in early 2016, appear to have substantially reduced ammonia concentrations in Silver Bow Creek downstream from the Butte WWTP (Site SS-07). Based on data collected from 2010-2018, ammonia concentrations in the stream at sites below the WWTP have decreased substantially since Q1 2016 (Figure 1-27). However, it appears that treatment methods in Q1 2018 may have deviated as ammonia was detected at all Silver Bow Creek sites downstream from the WWTP during that quarter (Figure 1-27).

Table 1-9. Total ammonia concentrations (mg/L) at Streamside Tailings Operable Unit monitoring stations, 2018.

ND Not detected at method detection limit.

J Estimated result either because sample result was below analytical reporting limit or because the associated field sample and duplicate pair had a relative percent difference greater than 25 percent.

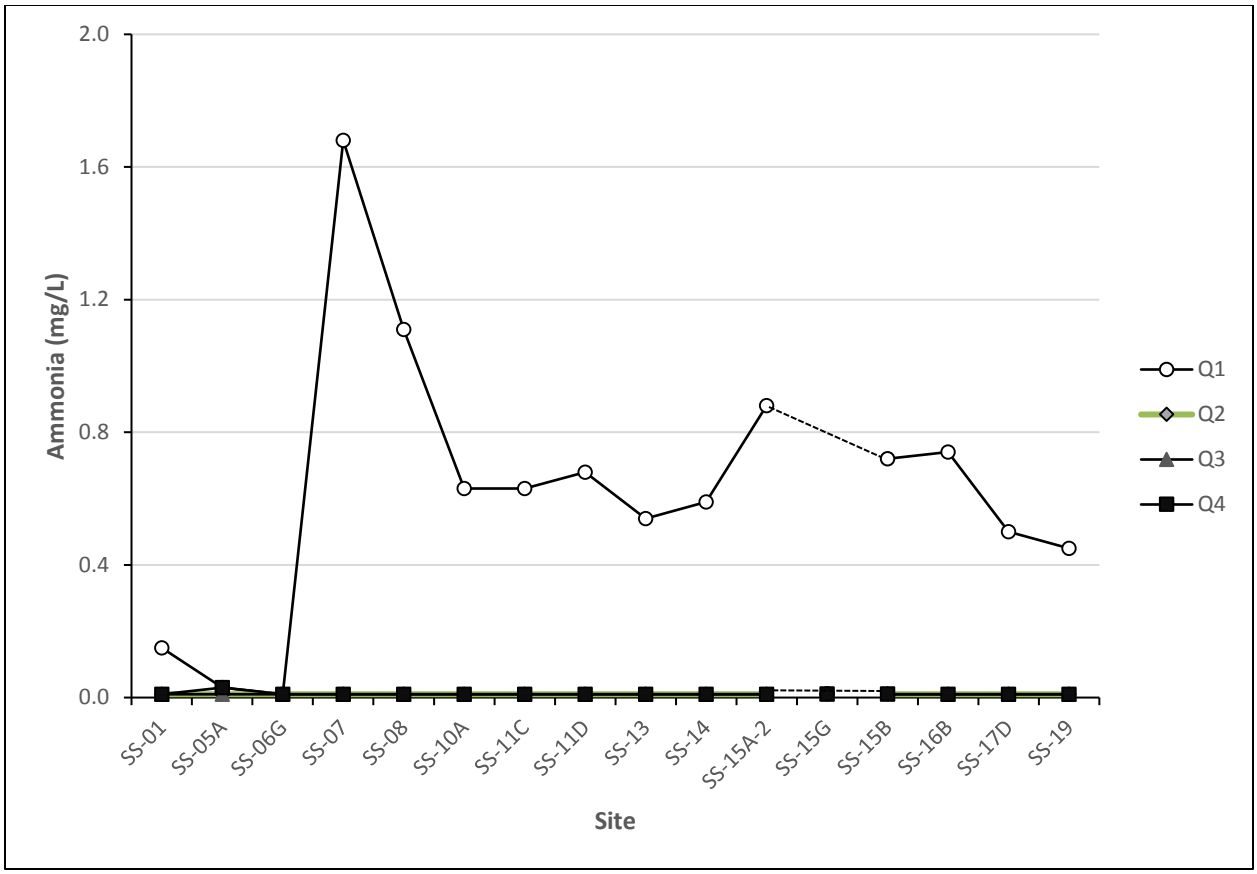

Figure 1-26. Ammonia concentrations at Streamside Tailings Operable Unit monitoring stations, 2018.

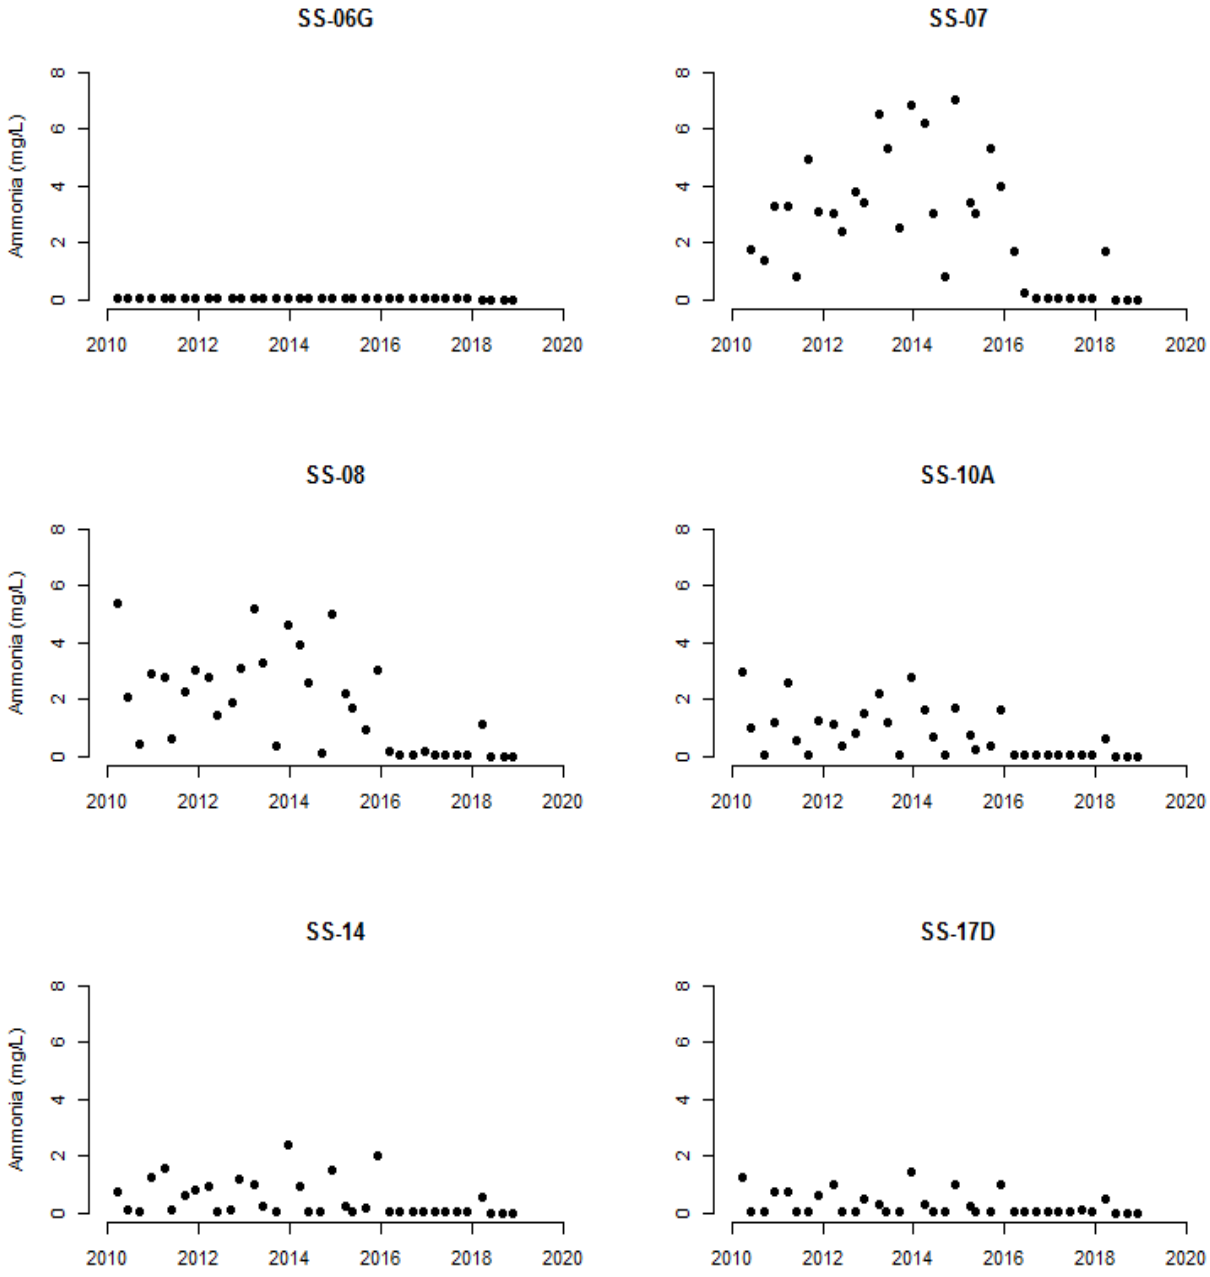

Figure 1-27. Ammonia concentrations (mg/L) at selected Silver Bow Creek sites in the Streamside Tailings Operable Unit: above Butte WWTP (Site SS-06G), below Butte WWTP (Site SS-07), at Rocker (Site SS-08), above Sand Creek (Site SS-10A), at Miles Crossing (Site SS-14), and at Opportunity (Site SS-17D).[14]

[14] One sample is not depicted: 11.2 mg/L at Site SS-07 on March 23, 2010.

1.4.5.4 Total Phosphorus

Total phosphorus concentrations in 2018 exceeded the total phosphorus standard at all Blacktail Creek and Silver Bow Creek sites (Table 1-10; Figure 1-28), but were generally low compared to prior monitoring years at sites downstream from the Butte WWTP (e.g., Sites SS-07, SS-08, SS-10a, SS-14, SS-17D; Figure 1-29). One sample collected in Q1 2018 in Blacktail Creek at Father Sheehan Park (Site SS-01) had a very high concentration which was more than three times higher than any other sample collected in the SSTOU in 2018 (Table 1-10; Figure 1-28). Concentrations in 2018 were lowest in Q3 and Q4, moderate in Q1 (except at Site SS-01), and highest in Q2 (Figure 1-28).

Table 1-10. Total phosphorus concentrations (mg/L) at Streamside Tailings Operable Unit monitoring stations, 2018.

Exceeds the 0.03 mg/L summertime base numeric nutrient standard for total phosphorus [DEQ, 2014].

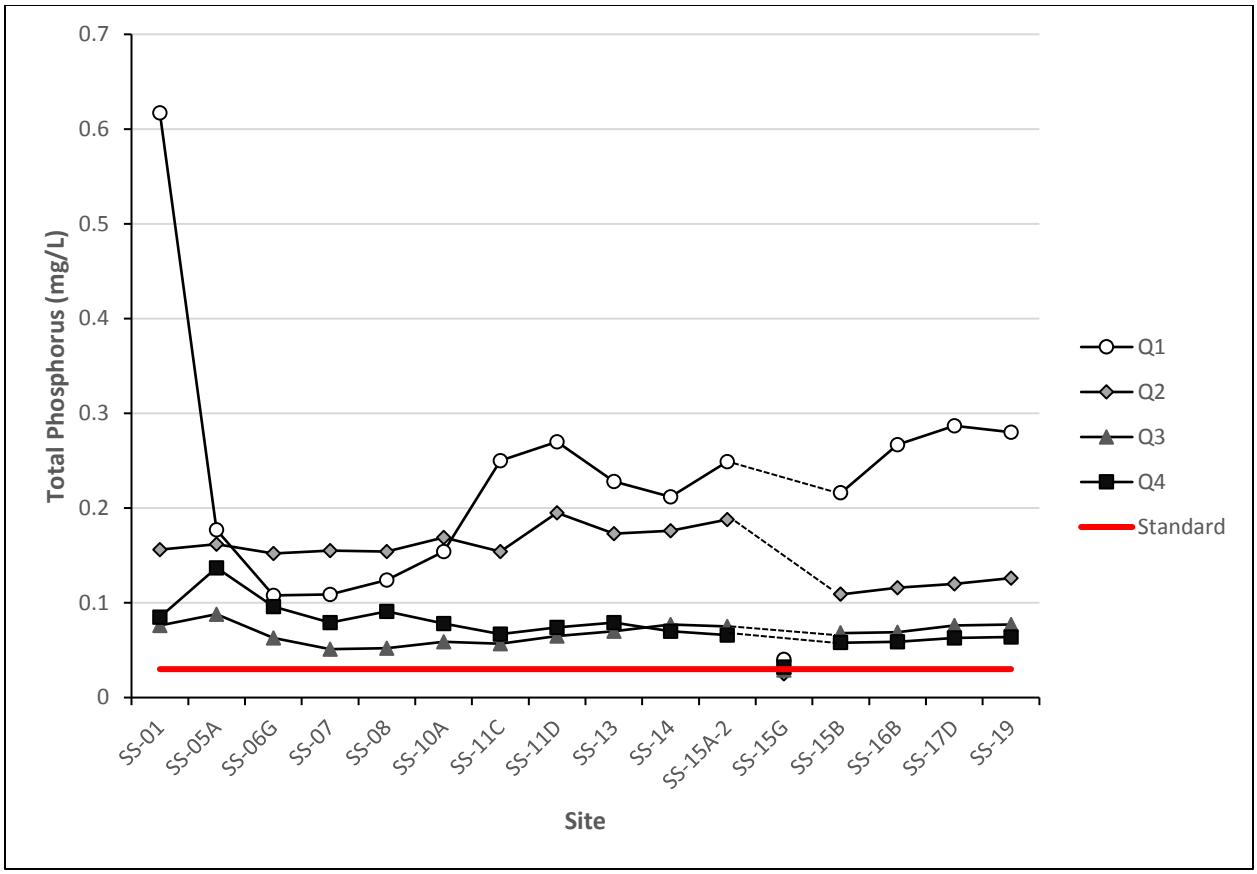

Figure 1-28. Total phosphorus concentrations at Streamside Tailings Operable Unit monitoring stations, 2018. Red line represents total phosphorus standard [DEQ, 2014].

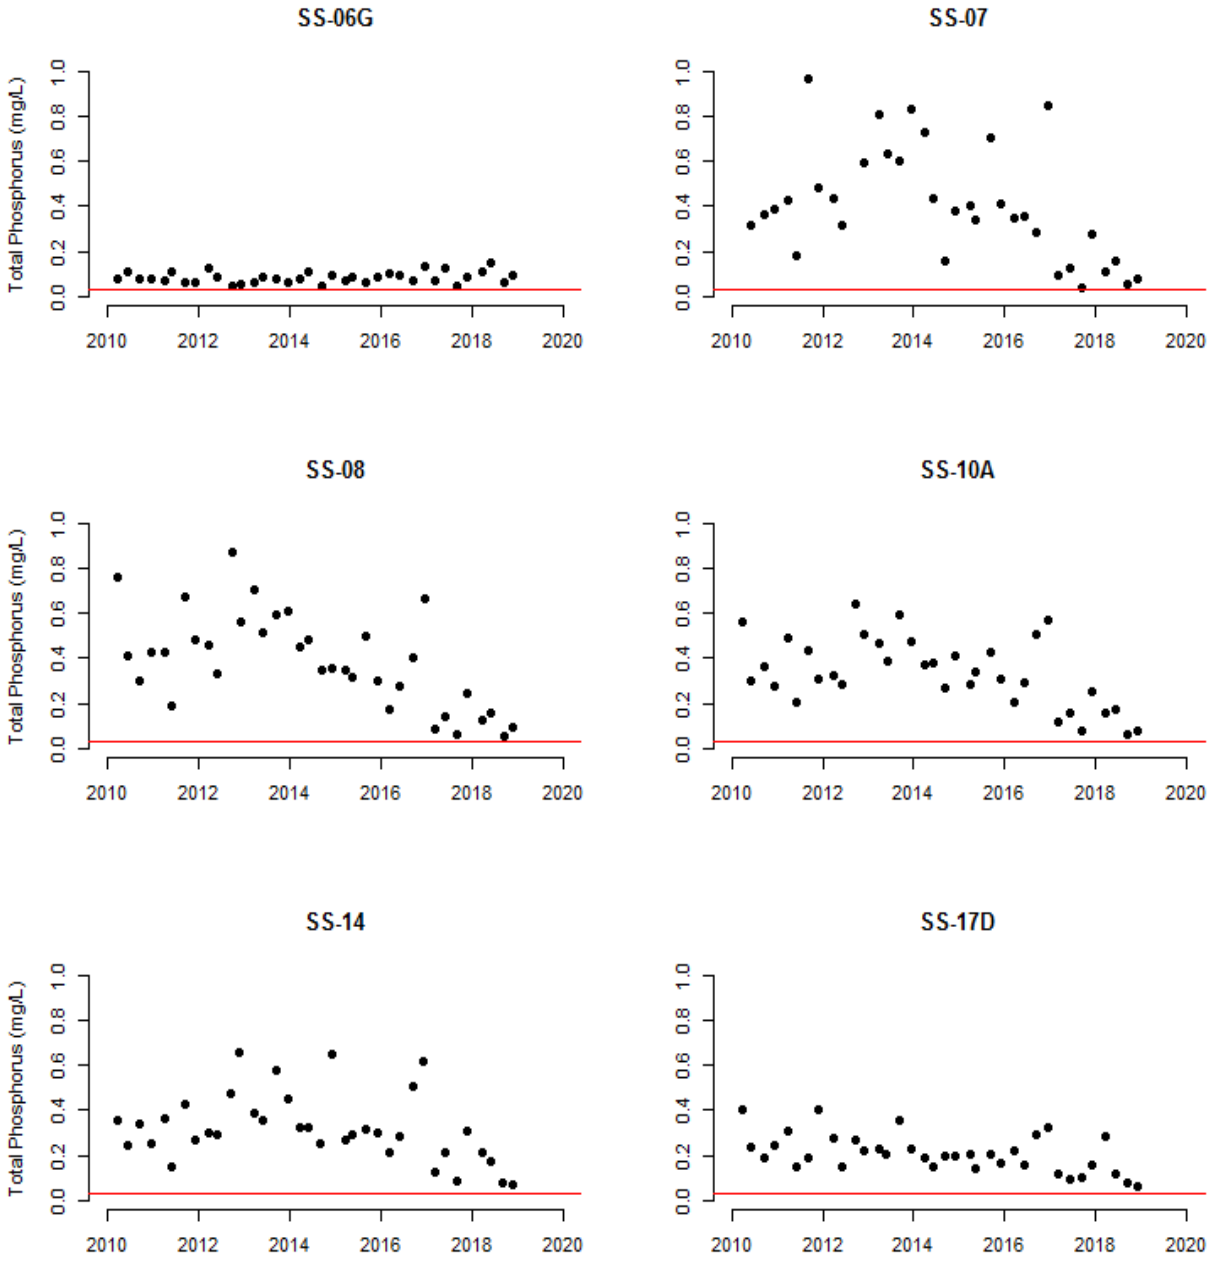

Figure 1-29. Total phosphorus concentrations (mg/L) at selected Silver Bow Creek sites in the Streamside Tailings Operable Unit: above Butte WWTP (Site SS-06G), below Butte WWTP (Site SS-07), at Rocker (Site SS-08), above Sand Creek (Site SS-10A), at Miles Crossing (Site SS-14), and at Opportunity (Site SS-17D). Red line represents the total phosphorus standard [DEQ, 2014].[15]

[15] Two SS-07 samples are not depicted: 1.37 mg/L on March 23, 2010 and 1.18 mg/L on September 20, 2012.

1.4.6 Contaminants of Concern

1.4.6.1 Arsenic

In 2018, total recoverable arsenic concentrations in the SSTOU ranged from 0.003-0.015 mg/L (Table 1-11). Ten Q1 samples and 13 Q2 samples exceeded the 0.010 mg/L human health surface water standard (Figure 1-30). Concentrations were highest in Q1 and Q2 and lowest in Q3 and Q4 (Figure 1-30). Q1 concentrations were highly variable in sites upstream from Subarea 2 (i.e., sites in Figure 1-30 left of Site SS-11C).

Compared to prior monitoring years (2010-2017), total recoverable arsenic concentrations in 2018 were generally similar in reference sites, although the Q1 and Q2 concentrations approached the higher end of the range of concentrations from prior monitoring periods (Figure 1-31). Concentrations in Subarea 1 and 2 sites in 2018 during Q1 and Q2 were also at the higher end of the range of concentrations for the monitoring period extending back to 2010 but concentrations in Q3 and Q4 were similar to prior concentrations (Figure 1-32; Figure 1-33). In Subareas 3 and 4, sample concentrations in Q3 and Q4 of 2018 appeared to continue the declining trends apparent from monitoring data since 2010 (Figure 1-34; Figure 1-35). In Q1 and Q2 of 2018, Subarea 3 and 4 site concentrations were relatively high (although not out of the range of prior samples) and slightly out of line with recent trends (Figure 1-34; Figure 1-35).

Exceeds the 0.010 mg/L human health standard [DEQ, 2017].

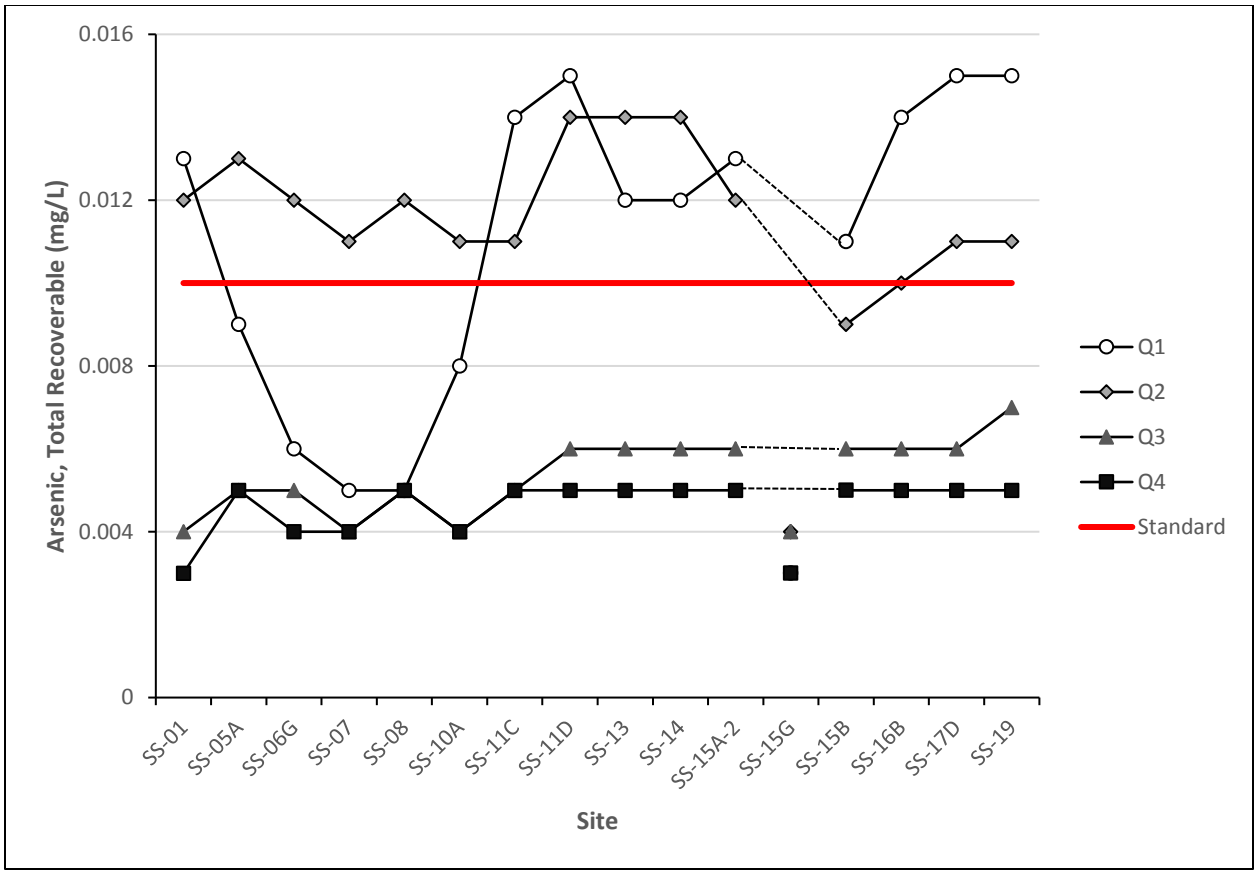

Figure 1-30. Total recoverable arsenic concentrations at Streamside Tailings Operable Unit monitoring stations, 2018. Red line represents the human health surface water standard [DEQ, 2017].

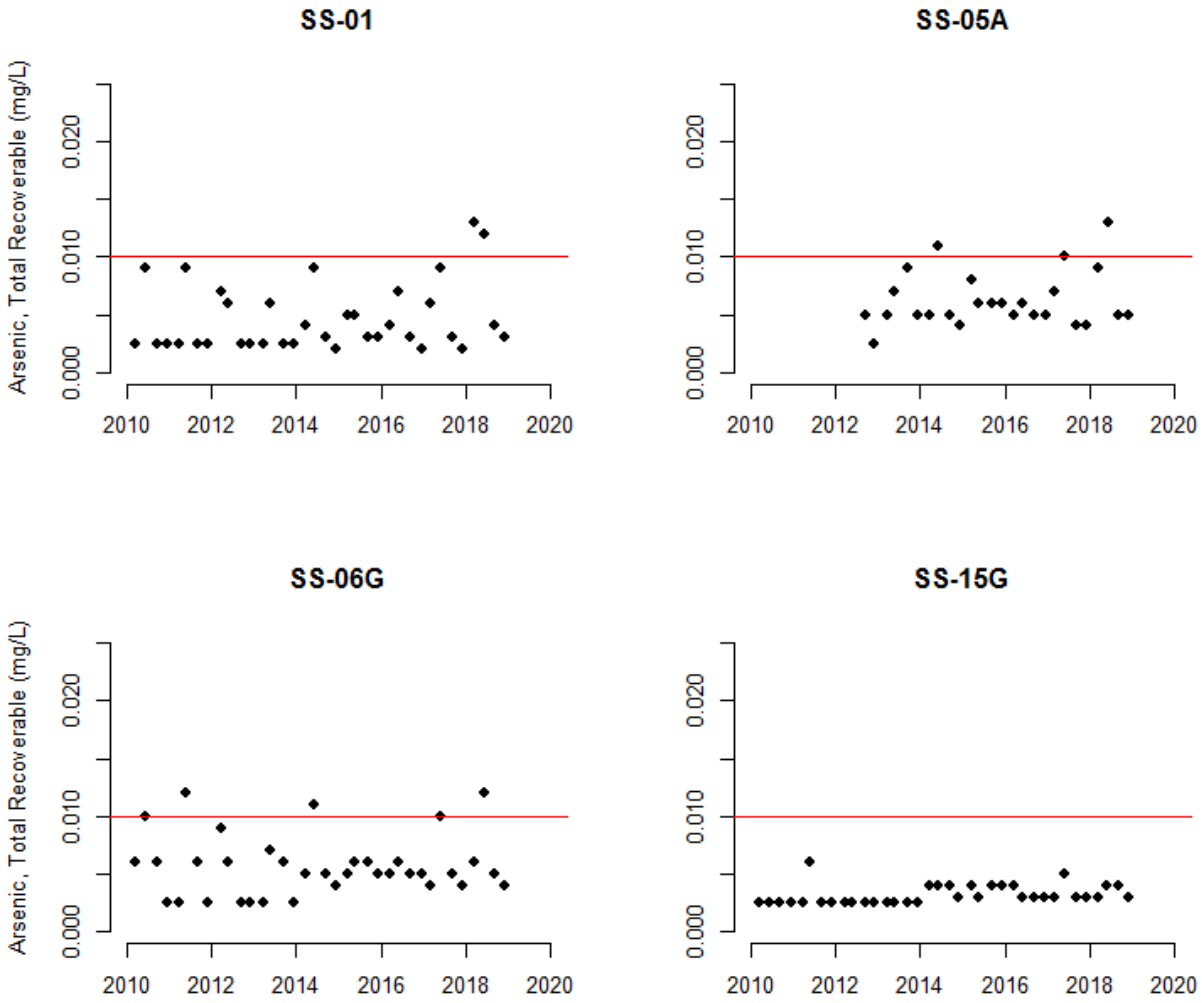

Figure 1-31. Total recoverable arsenic concentrations (mg/L) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Red line represents the human health surface water standard [DEQ, 2017].

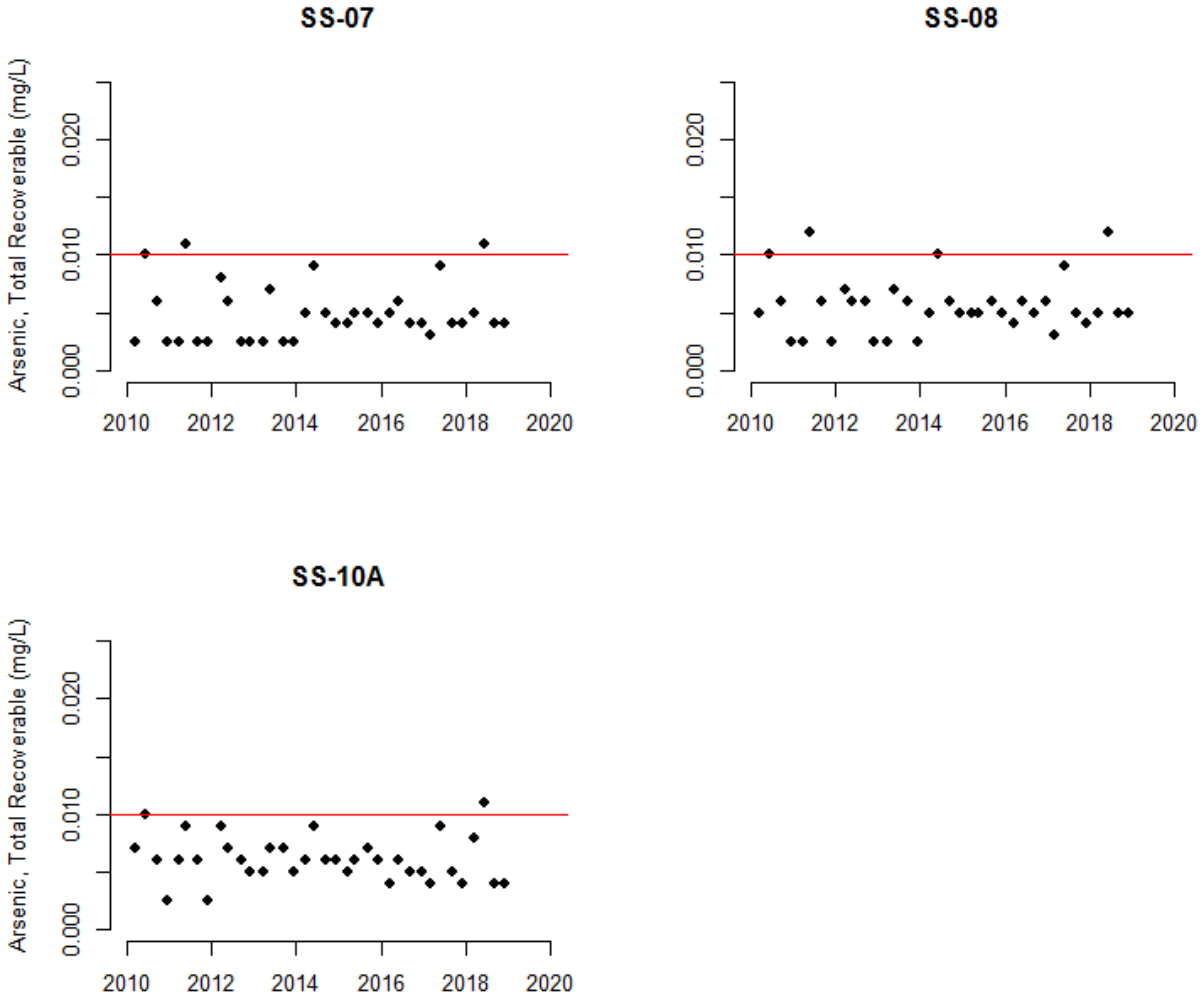

Figure 1-32. Total recoverable arsenic concentrations (mg/L) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Red line represents the human health surface water standard [DEQ, 2017].

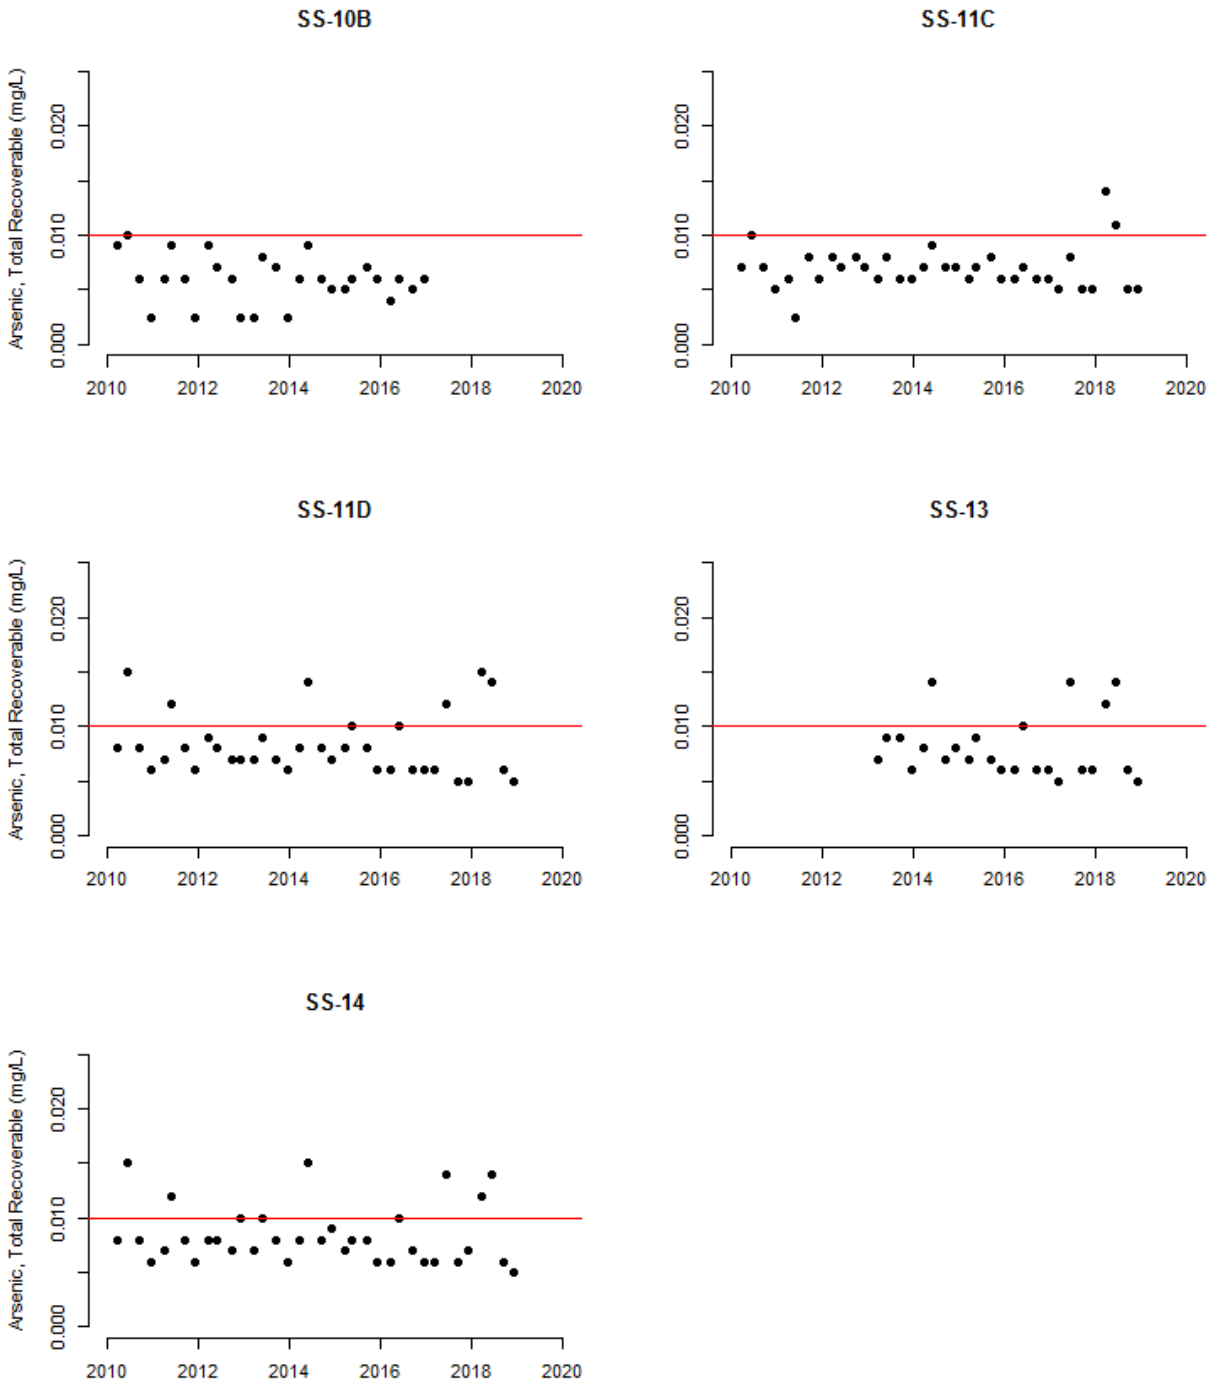

Figure 1-33. Total recoverable arsenic concentrations (mg/L) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Sand Creek (Site SS-10B), Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Red line represents the human health surface water standard [DEQ, 2017].

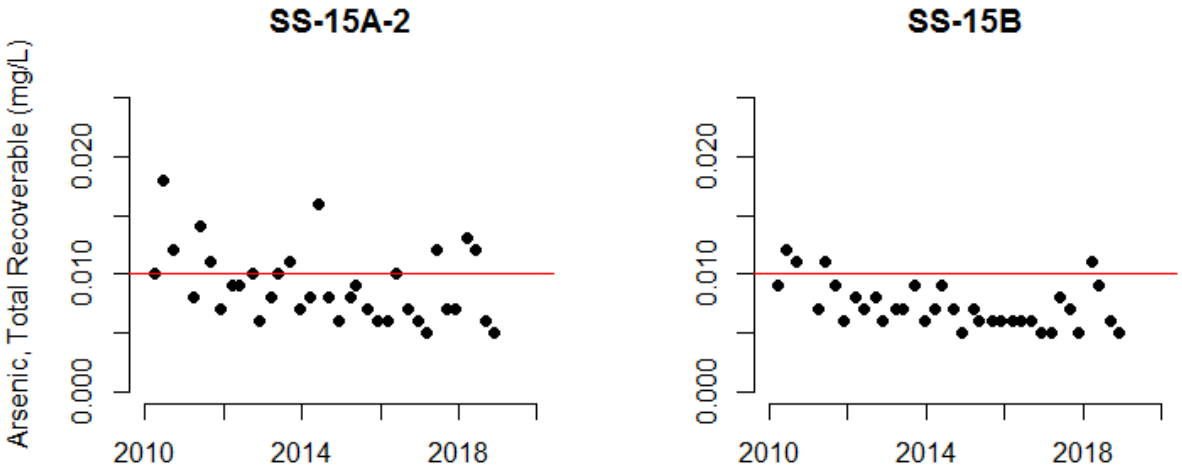

Figure 1-34. Total recoverable arsenic concentrations (mg/L) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-15A-2) and below (Site SS-15B) German Gulch. Red line represents the human health surface water standard [DEQ, 2017].[16, 17]

[16] Two outliers are not depicted: 0.111 mg/L at SS-15A and 0.060 mg/L at SS-15B on December 13, 2010.

[17] The scatterplot representing data at Site SS-15A-2 includes data from Site SS-15A in years prior to 2017. Site SS-15A was relocated approximately 100 m upstream and renamed (Site SS-15A-2) to better represent prevailing conditions in the remediated stream channel in Subarea 3 above German Gulch [see RESPEC, 2018a].

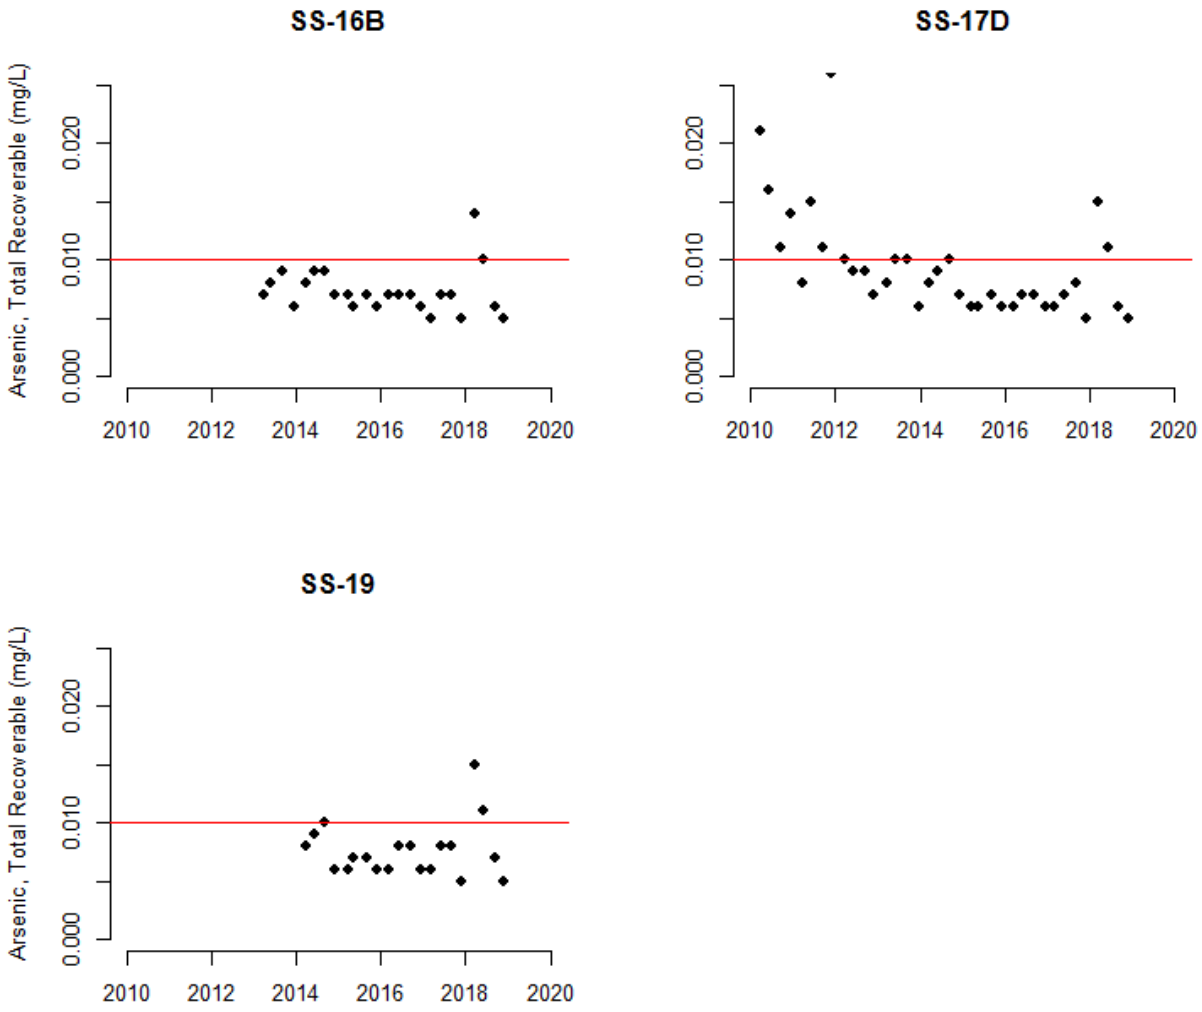

Figure 1-35. Total recoverable arsenic concentrations (mg/L) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Red line represents the human health surface water standard [DEQ, 2017].

1.4.6.2 Cadmium

In 2018, total recoverable cadmium concentrations in the SSTOU ranged from <0.00002-0.00073 mg/L (Table 1-12). No samples exceeded the human health chronic aquatic life standard (Table 1-12). Concentrations were generally highest in Q1 or Q4 and lowest in Q3 (Figure 1-36).

Compared to prior monitoring years (2010-2017), total recoverable cadmium concentrations in 2018 were generally similar in reference sites (Figure 1-37), Subarea 1 sites (Figure 1-38), and Subarea 2 sites (Figure 1-39). However, concentrations in Q1 2018 in the Blacktail Creek at Father Sheehan Park (Site SS-01) reference site were higher than in any prior monitoring period since 2010 (Figure 1-37). In Subarea 3 and 4, concentrations appear to have decreased steadily since 2010 in most sites but Q1 2018 concentrations were generally slightly higher than expected given the longer term trend (Figure 1-40).

Table 1-12. Total recoverable cadmium concentrations (mg/L) at Streamside Tailings Operable Unit monitoring stations, 2018.

Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017].

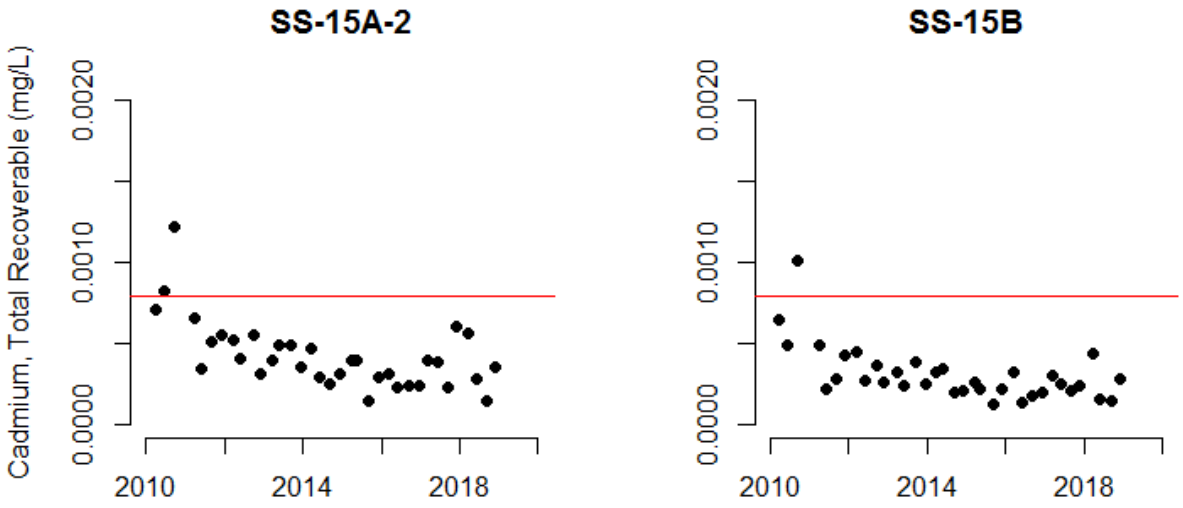

Figure 1-40. Total recoverable cadmium concentrations (mg/L) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-15A-2) and below (Site SS-15B) German Gulch. Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017].[18, 19]

[18] Two outliers are not depicted: 0.01180 mg/L at SS-15A and 0.00707 mg/L at SS-15B on December 13, 2010.

[19] The scatterplot representing data at Site SS-15A-2 includes data from Site SS-15A in years prior to 2017. Site SS-15A was relocated approximately 100 m upstream and renamed (Site SS-15A-2) to better represent prevailing conditions in the remediated stream channel in Subarea 3 above German Gulch [see RESPEC, 2018a].

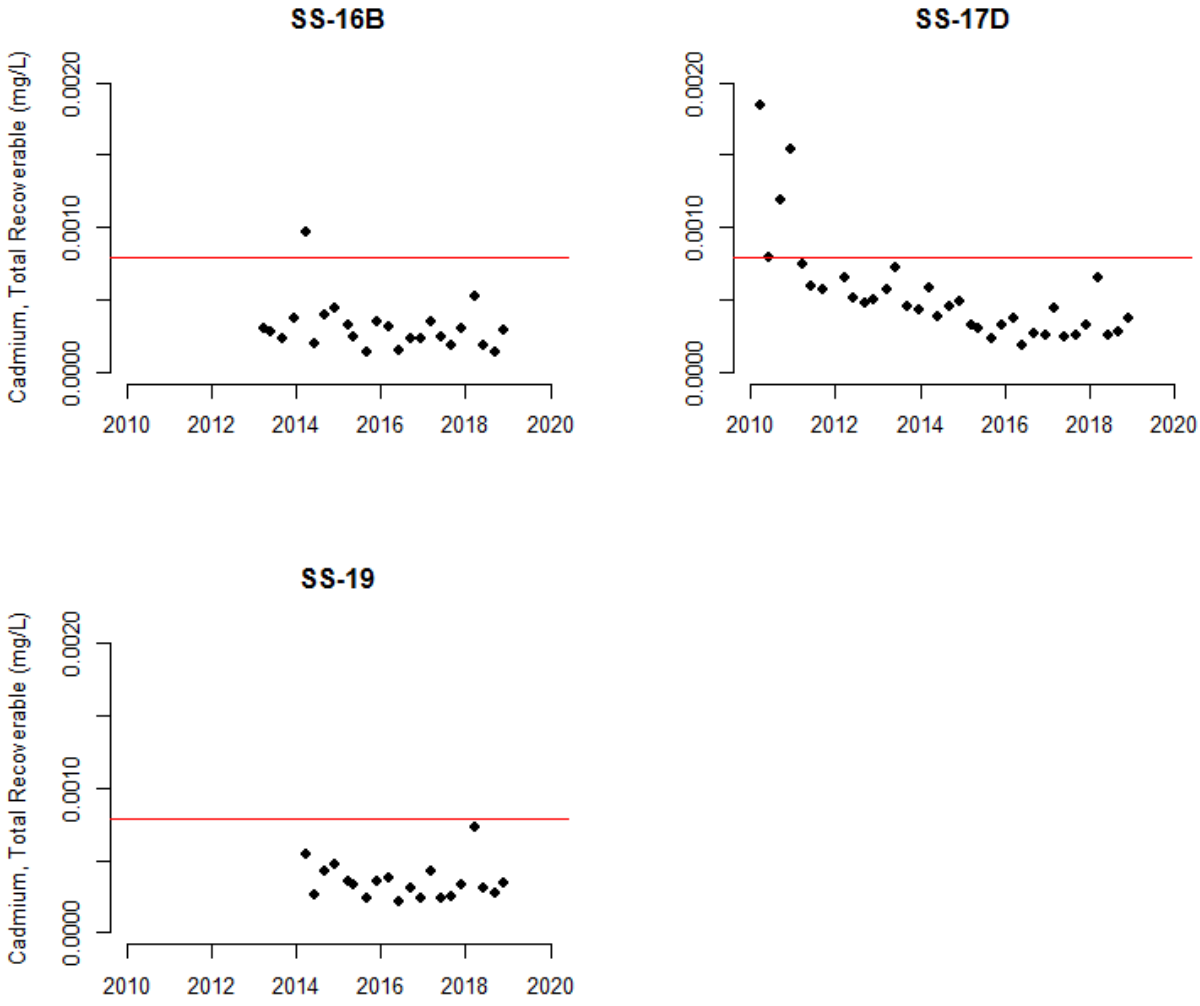

Figure 1-41. Total recoverable cadmium concentrations (mg/L) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017].

1.4.6.3 Copper

In 2018, total recoverable copper concentrations in the SSTOU ranged from 0.0008-0.046 mg/L (Table 1-13). Forty-three samples exceeded the chronic aquatic life standard and 29 also exceeded the acute standard (Table 1-13). Exceedances of the chronic standard occurred in all quarters but were least common in Q3 (Table 1-13). Exceedances of the acute standard also occurred in all quarters but were least common in Q3 and Q4 (Table 1-13). Concentrations were generally elevated in Q1, Q2, and Q4, and lowest in Q3 (Figure 1-42).

Compared to prior monitoring years (2010-2017), total recoverable copper concentrations in 2018 were similar in reference sites (except for Site SS-01 in Q1; Figure 1-43), Subarea 1 sites (Figure 1-44), and Subarea 2 sites (Figure 1-45). In Subarea 3, concentrations decreased sharply between 2010 and 2011 and appear to be declining slowly since then at both sites although Q1 and Q2 2018 concentrations were relatively high compared to recent trends (Figure 1-46). In Subarea 4, no trend is apparent at sites monitored only since 2013, but at Opportunity (Site SS-17D which has been monitored since 2010), a sharp decrease occurred between 2011 and 2012 and concentrations appear to be slowly declining since then (Figure 1-47). As with the Subarea 3 sites, Q1 and Q2 2018 concentrations were relatively high at Site SS-17D (Figure 1-47).

Table 1-13. Total recoverable copper concentrations (mg/L) at Streamside Tailings Operable Unit monitoring stations, 2018.

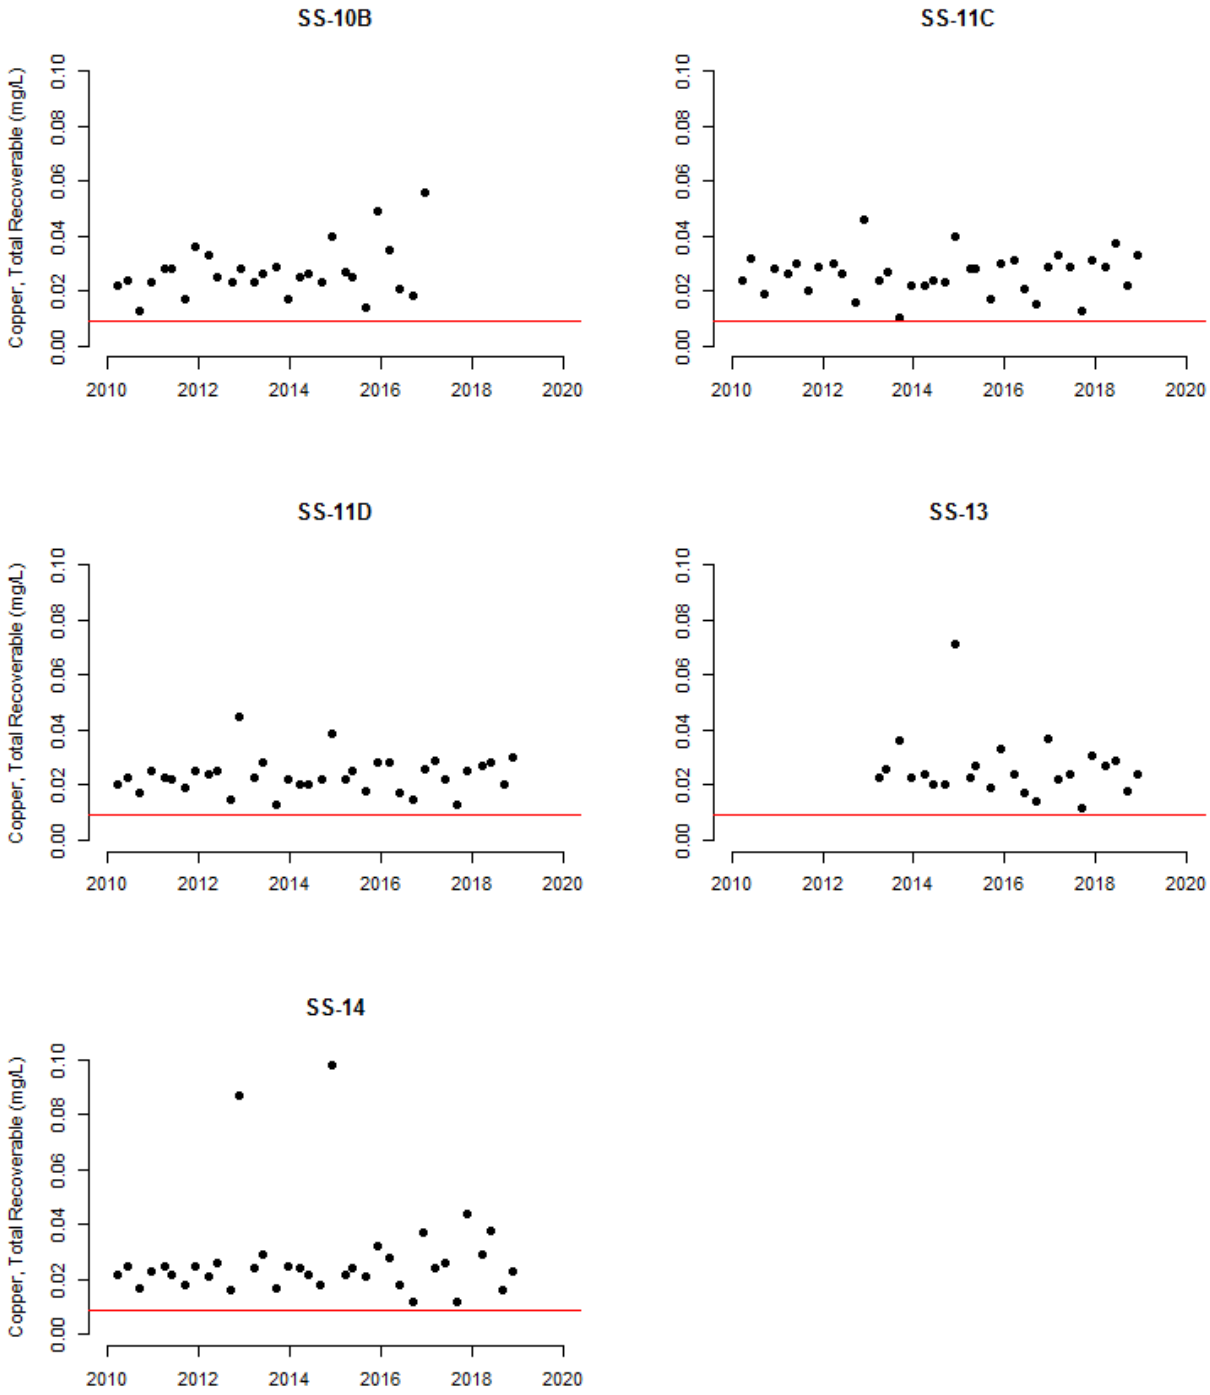

Figure 1-45. Total recoverable copper concentrations (mg/L) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Sand Creek (Site SS-10B), Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017].

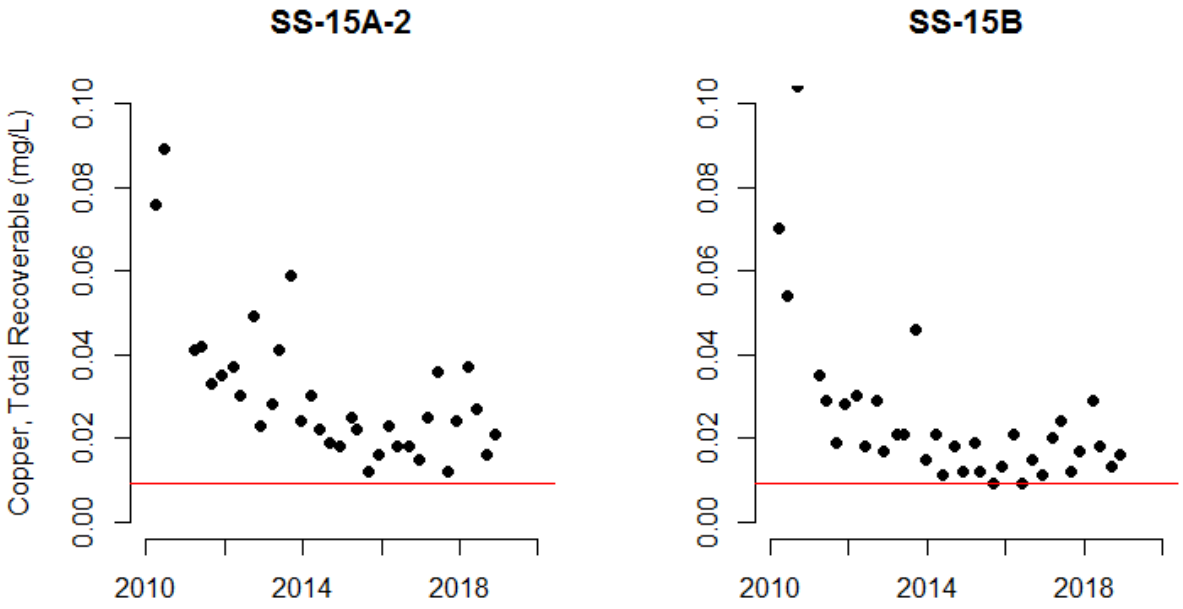

Figure 1-46. Total recoverable copper concentrations (mg/L) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-15A-2)[20],[21] and below (Site SS-15B) [22] German Gulch. Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017].

[20] Two outliers are not depicted for Site SS-15A-2: 0.131 mg/L on September 14, 2010 and 2.01 mg/L on December 13, 2010.

[21] The scatterplot representing samples at Site SS-15A-2 include samples from Site SS-15A in years prior to 2017. Site SS-15A was relocated approximately 100 m upstream and renamed (Site SS-15A-2) to better represent prevailing conditions in the remediated stream channel in Subarea 3 above German Gulch [see RESPEC, 2018a].

[22] One outlier is not depicted for Site SS-15B: 1.25 mg/L on December 13, 2010.

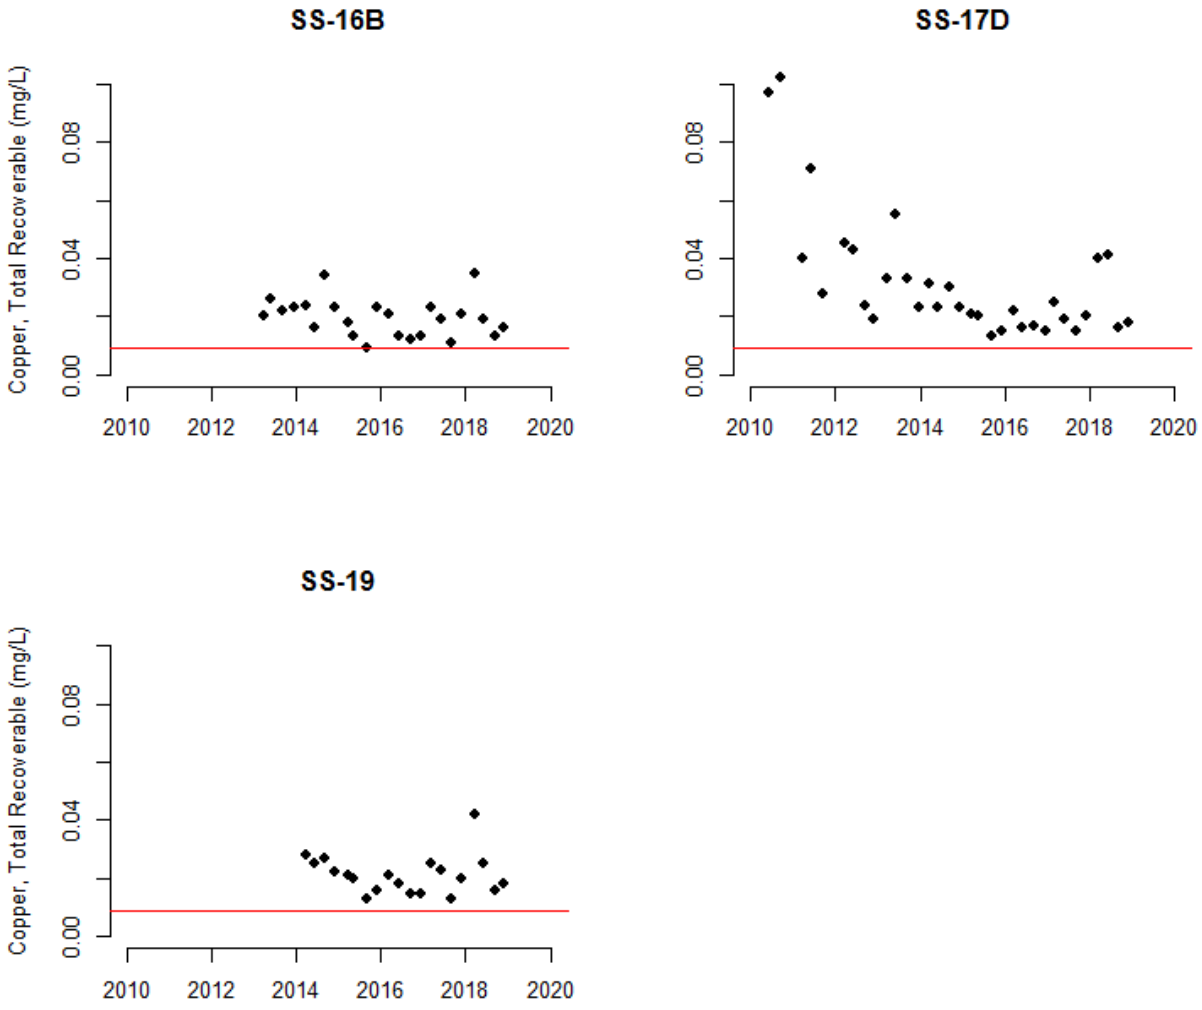

Figure 1-47. Total recoverable copper concentrations (mg/L) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D)[23], and Silver Bow Creek at Frontage Road (Site SS-19). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017].

[23] Three outliers are not depicted for Site SS-17D: 0.169 mg/L on March 23, 2010, 0.158 mg/L on December 13, 2010, and 0.301 mg/L on November 29, 2011.

1.4.6.4 Lead

In 2018, total recoverable lead concentrations in the SSTOU ranged from <0.00004-0.0164 mg/L (Table 1-14). Five samples had concentrations exceeding the chronic aquatic life standard: 2 samples collected in Q1, 2 samples collected in Q2, and 1 sample collected in Q4 (Table 1-14). Three samples had particularly elevated concentrations in 2018 relative to others; specifically, the samples from Sites SS-01 and SS-05A in Q1 and from Site SS-17D in Q2 (Figure 1-48). Seasonally, concentrations at most sites in 2018 tended to be highest in Q1 and Q2, but there were multiple local deviations from that seasonal trend (Figure 1-48).

Compared to prior monitoring years (2010-2017), total recoverable lead concentrations in reference sites were generally similar to prior years although the Q1 2018 concentration in Blacktail Creek at Father Sheehan Park (Site SS-01) and Silver Bow Creek above the Butte Reduction Works (Site SS-05A) were relatively high (Figure 1-49). Similarly, concentrations at those sites in Q1 2017 were also elevated (Figure 1-49). Concentrations at sites in Subareas 1, 2, and 3 were generally consistent with recent trends which appeared to be generally flat in Subareas 1 and 2 and declining in Subarea 3 since 2010 (Figure 1-50; Figure 1-51; Figure 1-52). In Subarea 4, concentrations have been consistent at sites monitored only since 2013 (i.e., Sites SS-16B and SS-19), but at Opportunity (monitored since 2010) concentrations decreased have decreased since 2013 although the Q2 2018 were high compared to recent results (Figure 1-53).

Table 1-14. Total recoverable lead concentrations (mg/L) at Streamside Tailings Operable Unit monitoring stations, 2018.

Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017].

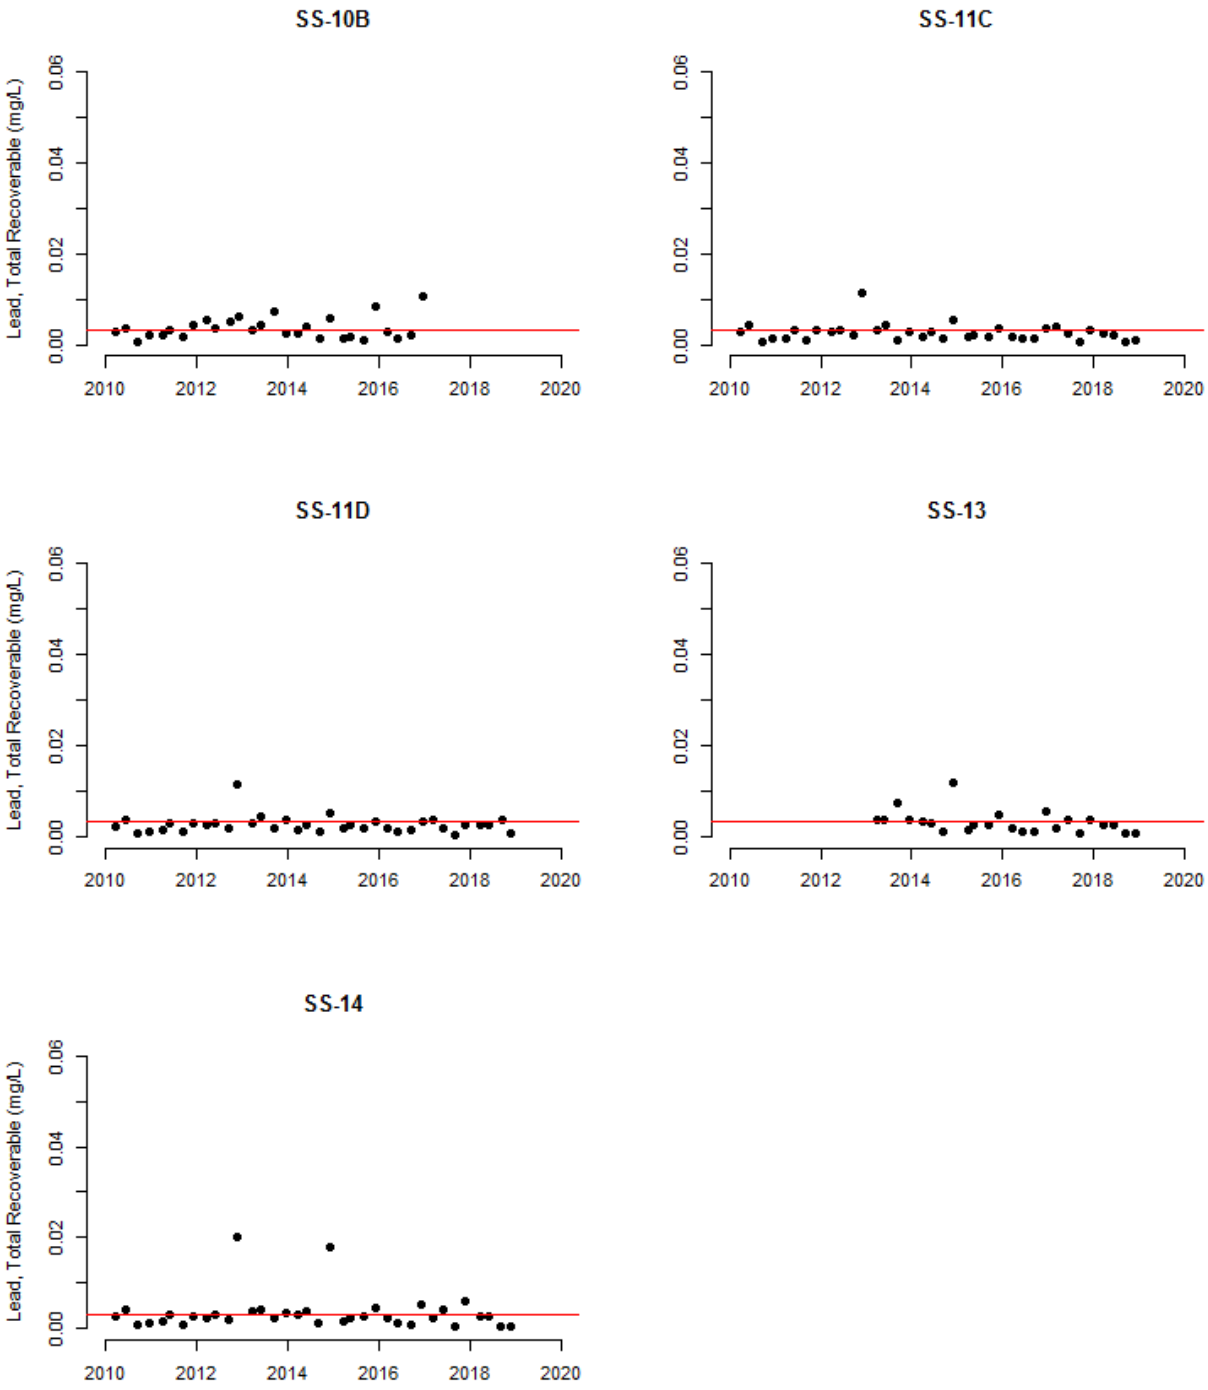

Figure 1-51. Total recoverable lead concentrations (mg/L) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Sand Creek (Site SS-10B), Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017].

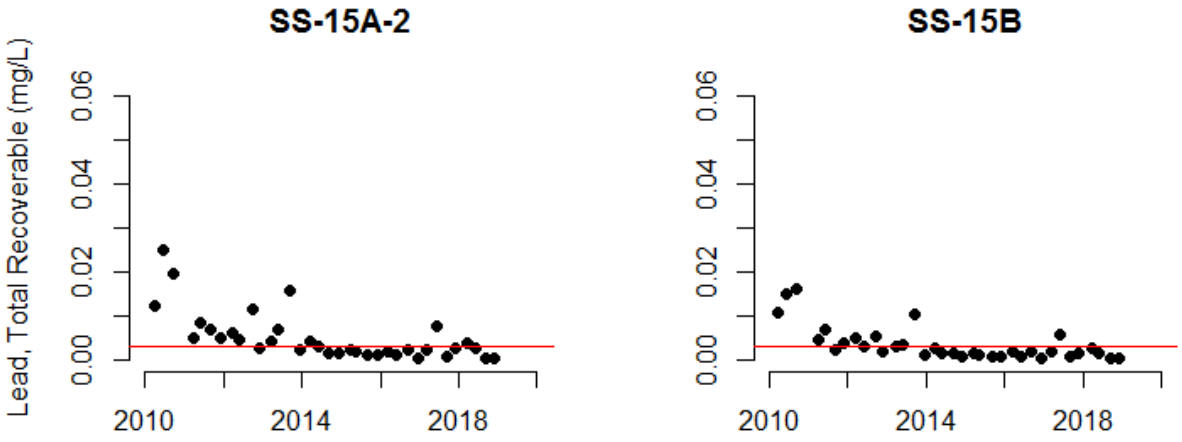

Figure 1-52. Total recoverable lead concentrations (mg/L) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-15A-2) and below (Site SS-15B) German Gulch. Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017].[24, 25]

[24] Two outliers are not depicted: 0.785 mg/L at SS-15A and 0.435 mg/L at SS-15B on December 13, 2010.

[25] The scatterplot representing data at Site SS-15A-2 includes data from Site SS-15A in years prior to 2017. Site SS-15A was relocated approximately 100 m upstream and renamed (Site SS-15A-2) to better represent prevailing conditions in the remediated stream channel in Subarea 3 above German Gulch [see RESPEC, 2018a].

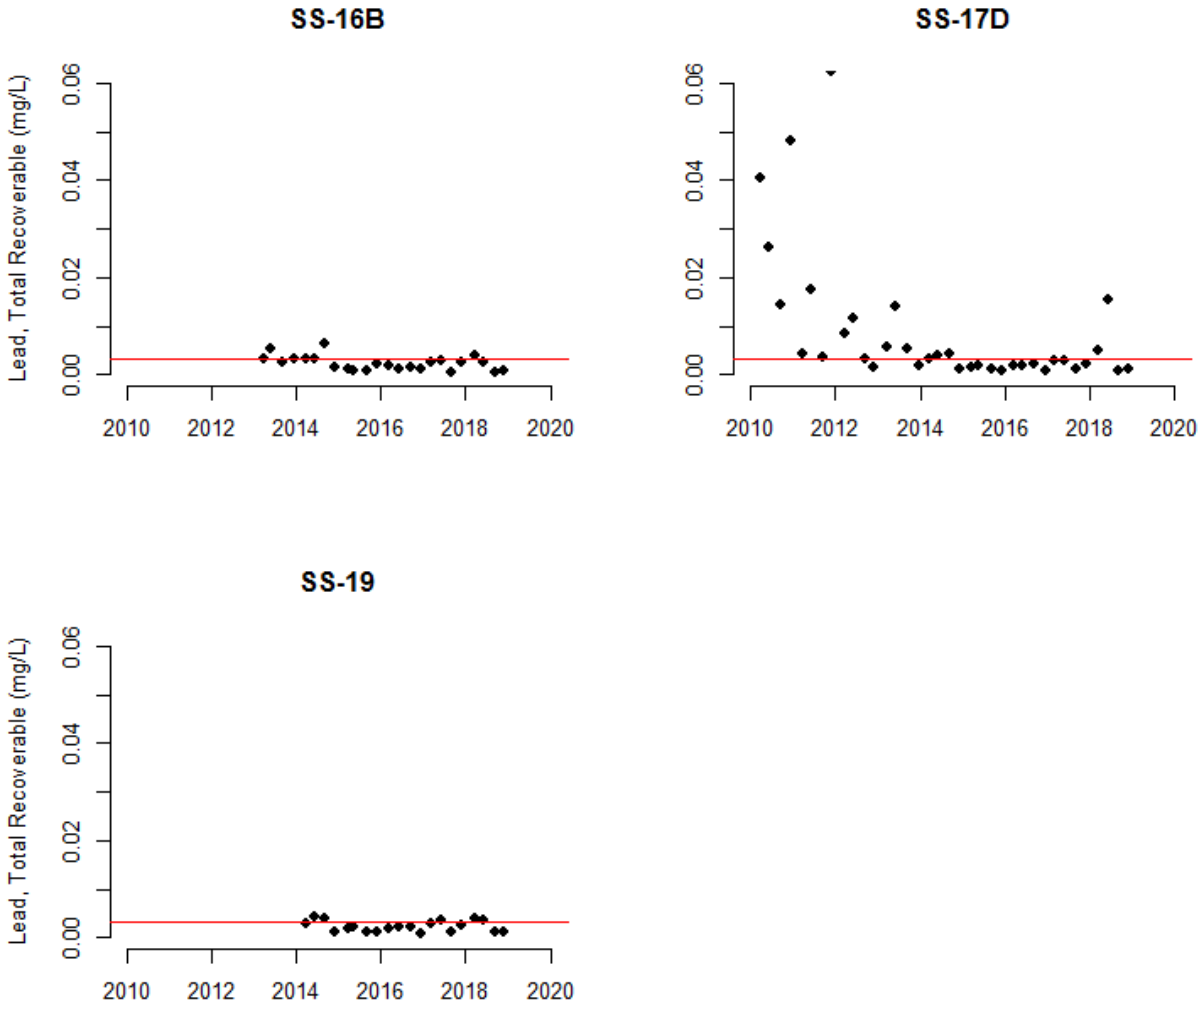

Figure 1-53. Total recoverable lead concentrations (mg/L) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [DEQ, 2017].

1.4.6.5 Mercury

In 2018, total recoverable mercury concentrations in the SSTOU ranged from <0.001-0.037 µg/L (Table 1-15). Twenty-two samples exceeded the 0.012 µg/L chronic aquatic life standard (Table 1-15). Concentrations were generally lowest in Q3 although concentrations were highly variable among sites and monitoring periods, particularly in the Subarea 1 and 2 sites (i.e., Sites SS-07, SS-08, SS-10A, SS-11C, SS-11D, SS-13, and SS-14) (Figure 1-54). Concentrations were highest in the upstream-most sites (reference Sites SS-01 and SS-05A) and in the downstream-most sites (Sites SS-17D and SS-19) during Q1 (Figure 1-54). For comparison with regional streams with well-known mercury contamination, the highest total recoverable mercury concentration observed in the SSTOU in 2018 (0.037 µg/L) was an order of magnitude lower than the highest concentration observed in Flint Creek in 2018 (0.640 µg/L) on May 9, 2018; RESPEC [2018a]). Flint Creek is also a tributary to the Clark Fork River.

Long-term trends (2010-2017) for total recoverable mercury concentrations are difficult to discern at many sites because the reporting limits prior to 2014 were high (at least 0.050 µg/L) which is more than four times higher than the SSTOU performance goal (Table 1-1). Prior to lowering the reporting limits in 2014, the majority of samples in reference sites (Figure 1-55), Subarea 1 sites (Figure 1-56), Subarea 2 sites (Figure 1-57), and Site SS-15B in Subarea 3 (Figure 1-58) had concentrations below the 0.050 µg/L reporting limit which renders those data to be of limited use for identifying temporal trends (particularly downward trends) from 2010-2018. Despite the high mercury reporting limits, for the pre-2014 samples, concentrations at some sites appear to have decreased through time, specifically: Silver Bow Creek in Reach L (Site SS-13) particularly from 2013 to 2017 (Figure 1-57), Silver Bow Creek above German Gulch (Site SS-15A-2) (Figure 1-58), Silver Bow Creek at Fairmont (Site SS-16B) (Figure 1-59), and Silver Bow Creek at Opportunity (Site SS-17D) (Figure 1-59).

Table 1-15. Total recoverable mercury concentrations (µg/L) at Streamside Tailings Operable Unit monitoring stations, 2018.

ND — Not detected at method detection limit.

J — Estimated result either because sample result was below analytical reporting limit or because the associated field sample and duplicate pair had a relative percent difference greater than 25 percent.

Exceeds the chronic aquatic life standard [MDHES, 1994].

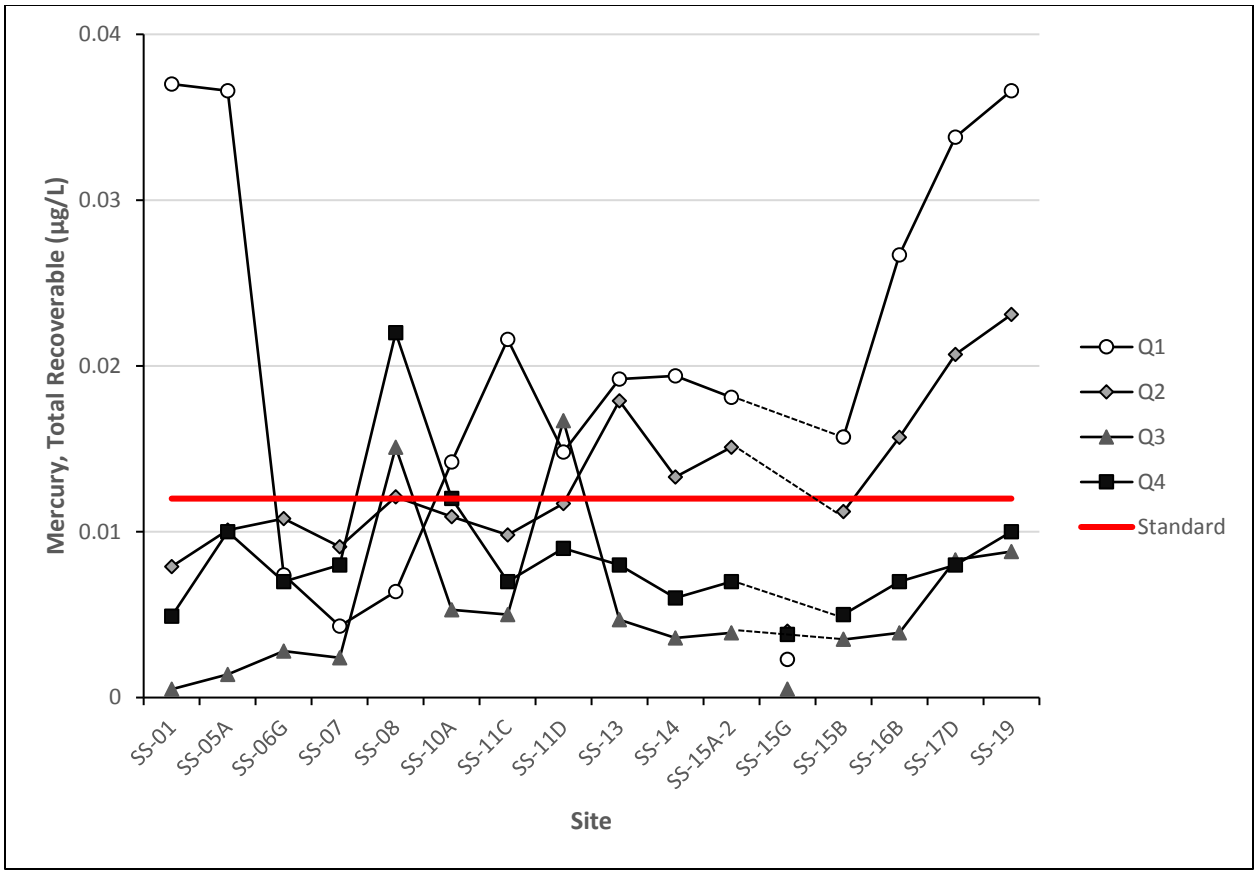

Figure 1-54. Total recoverable mercury concentrations at Streamside Tailings Operable Unit monitoring stations, 2018. Red line represents the chronic aquatic life standard [MDHES, 1994].

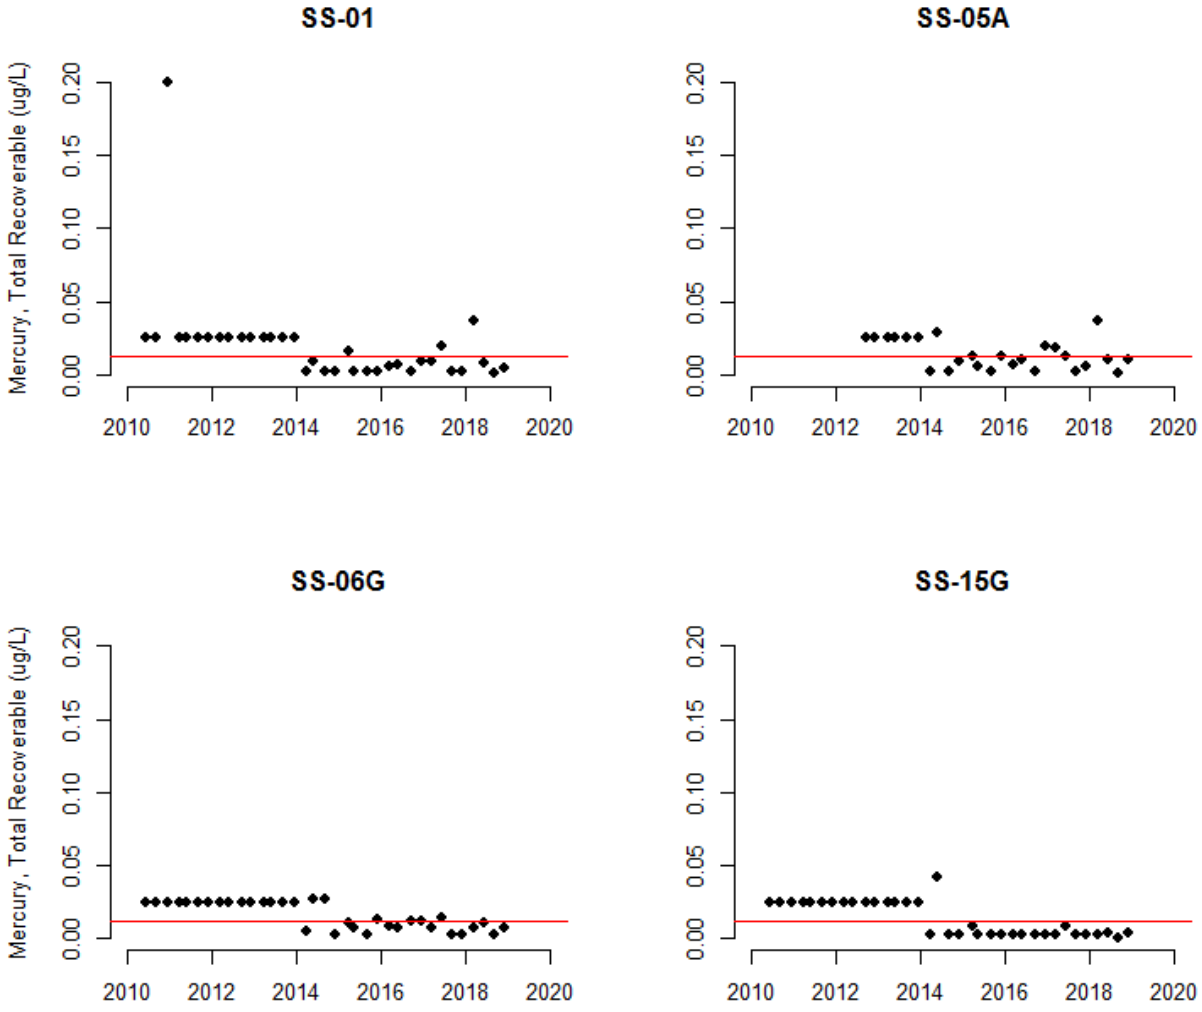

Figure 1-55. Total recoverable mercury concentrations in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Red line represents the chronic aquatic life standard [MDHES, 1994].[26]

[26] Samples collected on March 23, 2010 are not included because the reporting limit was high (1 µg/L).

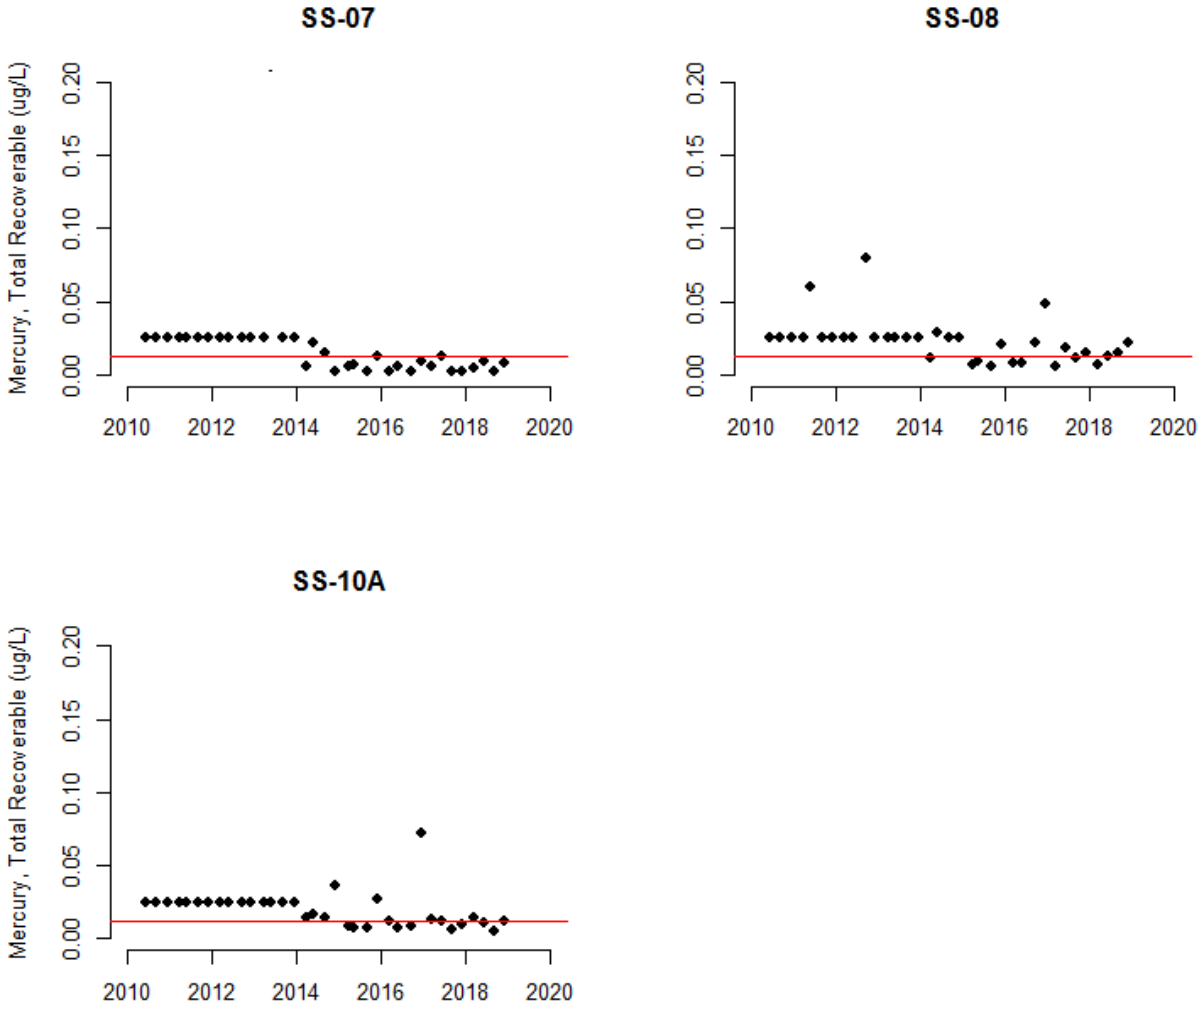

Figure 1-56. Total recoverable mercury concentrations in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Red line represents the chronic aquatic life standard [MDHES, 1994].[27]

[27] Samples collected on March 23, 2010 are not included because the reporting limit was high (1 µg/L).

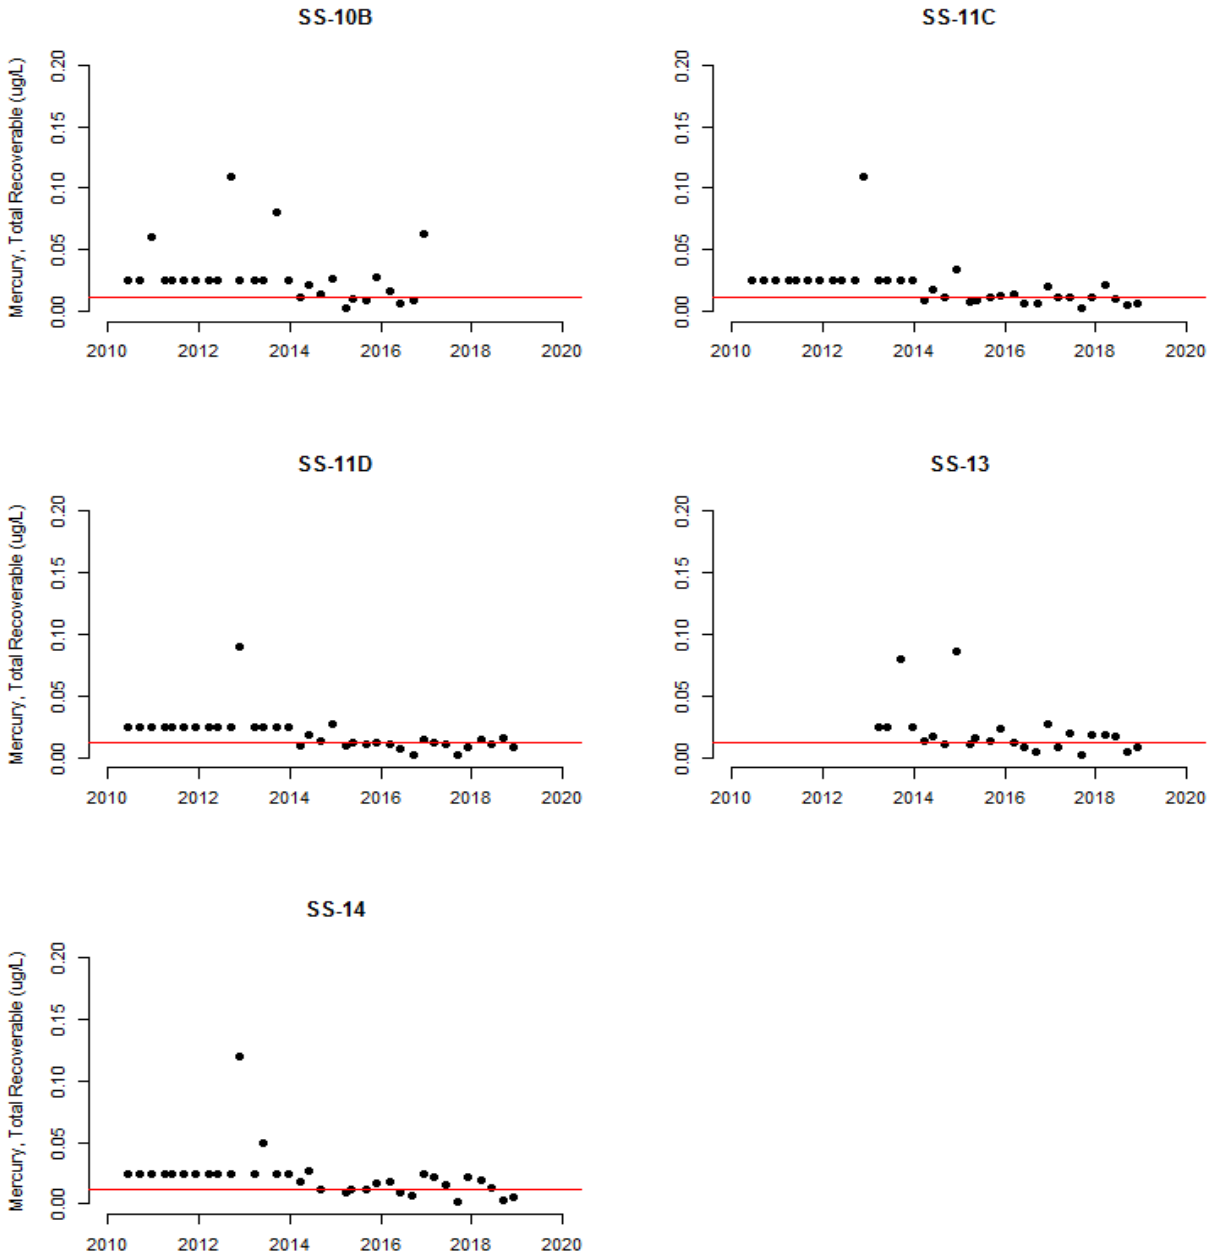

Figure 1-57. Total recoverable mercury concentrations in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Sand Creek (Site SS-10B), Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Red line represents the chronic aquatic life standard [MDHES, 1994].[28] [29]

[28] Samples collected on March 23, 2010 are not included because the reporting limit was high (1 µg/L).

[29] One outlier is not depicted: 0.36 µg/L at Site SS-14 on December 3, 2014.

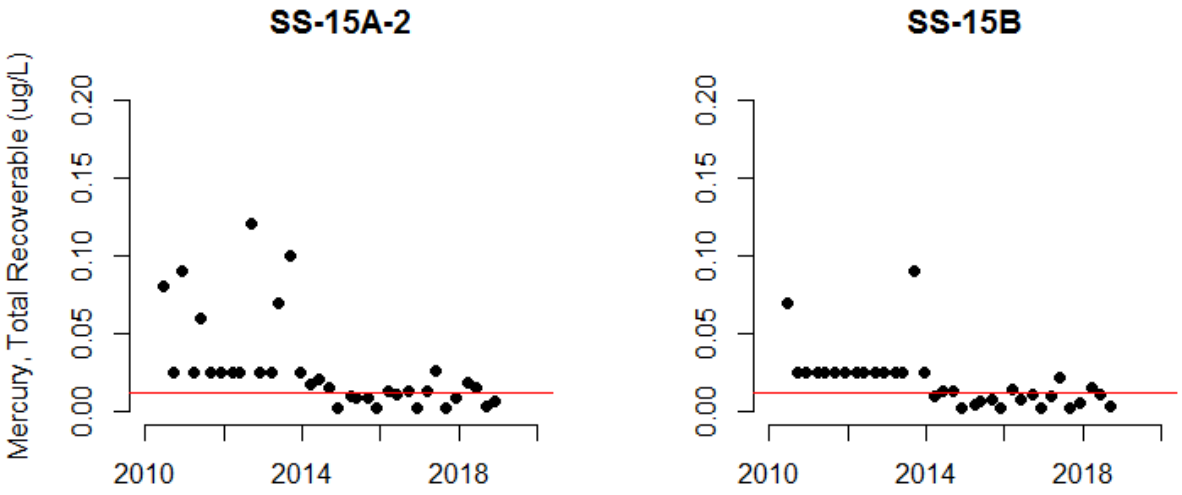

Figure 1-58. Total recoverable mercury concentrations in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-15A-2) and below (Site SS-15B) German Gulch. Red line represents the chronic aquatic life standard [MDHES, 1994].[30]

[30] The scatterplot representing data at Site SS-15A-2 includes data from Site SS-15A in years prior to 2017. Site SS-15A was relocated approximately 100 m upstream and renamed (Site SS-15A-2) to better represent prevailing conditions in the remediated stream channel in Subarea 3 above German Gulch (see RESPEC [2018a]).

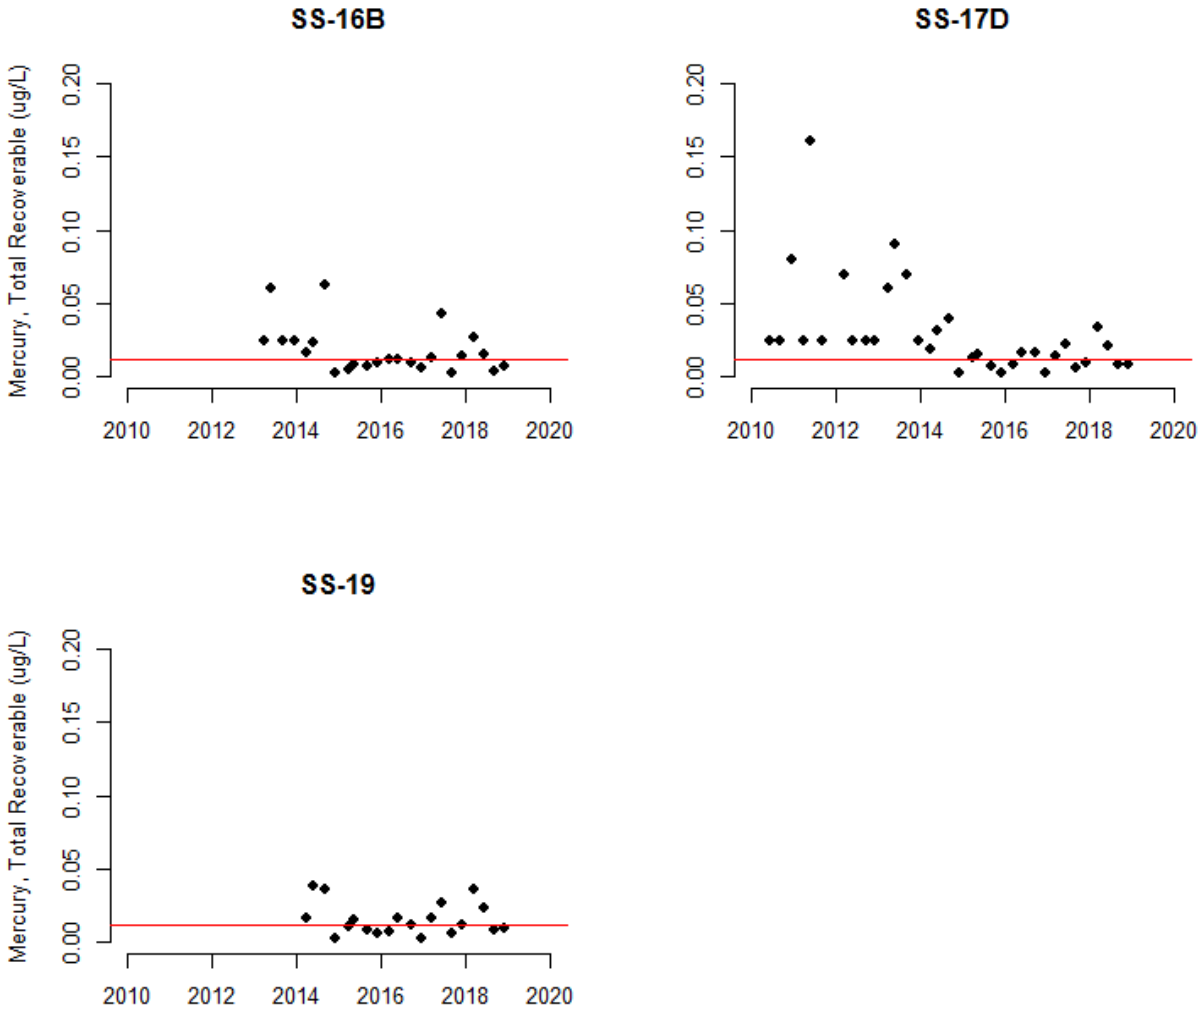

Figure 1-59. Total recoverable mercury concentrations in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Red line represents the chronic aquatic life standard [MDHES, 1994].[31] [32]

[31] Samples collected on March 23, 2010 are not included because the reporting limit was high (1 µg/L).

[32] One outlier is not depicted: 0.34 µg/L at Site SS-17D on November 29, 2011.

1.4.6.6 Zinc

In 2018, total recoverable zinc concentrations in the SSTOU ranged from 0.002-0.176 mg/L (Table 1-16). One sample exceeded the chronic aquatic life standard and another also exceeded the acute standard, both of which were in lower Subarea 4 sites during Q1 (Sites SS-17D and SS-19; Table 1-16; Figure 1-60). Concentrations were generally highest in Q1 or Q4 and lowest in Q2 or Q3 (Figure 1-60).

Compared to prior monitoring years (2010-2017), total recoverable zinc concentrations in 2018 were generally similar in reference sites (Figure 1-61), Subarea 1 sites (Figure 1-62), and Subarea 2 sites (Figure 1-63). In Subarea 3, concentrations appear to be decreasing in both sites since 2011 (Figure 1-64). In Subarea 4, concentrations have been consistent in Silver Bow Creek near Fairmont (SS-16B) and at Frontage Road (SS-19) whereas concentrations at Opportunity (SS-17D) appear to have declined since 2010 (Figure 1-65).

Table 1-16. Total recoverable zinc concentrations (mg/L) at Streamside Tailings Operable Unit monitoring stations, 2018.

Red line represents the chronic aquatic life standard assuming hardness is 100 mg/L [MDHES, 1994].

1.4.7 Other Metals

1.4.7.1 Aluminum

Dissolved aluminum was detected at concentrations above the method detection limit (0.003 mg/L) in 63 percent of the samples (40 of 64) collected in 2018; concentrations ranged from <0.003-0.021 mg/L. No samples had dissolved aluminum concentrations exceeding the DEQ [2017] standards.

Total recoverable aluminum was detected at concentrations above the method detection limit in 100 percent of the samples (64 of 64) in 2018; concentrations ranged from 0.022-2.91 mg/L.

1.4.7.2 Antimony

Dissolved antimony was detected at concentrations above the method detection limit (0.00009 mg/L) in 80 percent of the samples (51 of 64) collected in 2018; concentrations ranged from <0.00009-0.00060 mg/L.

Total recoverable antimony was detected at concentrations above the method detection limit in 78 percent of the samples (50 of 64) in 2018; concentrations ranged from <0.0001-0.0008 mg/L. No samples had total recoverable antimony concentrations exceeding the DEQ [2017] standards.

1.4.7.3 Barium

Dissolved barium was detected at concentrations above the method detection limit (0.00002 mg/L) in 100 percent of the samples (64 of 64) collected in 2018; concentrations ranged from 0.019-0.054 mg/L.

Total recoverable barium was detected at concentrations above the method detection limit in 100 percent of the samples (64 of 64) in 2018; concentrations ranged from 0.020-0.069 mg/L. No samples had total recoverable barium concentrations exceeding the DEQ [2017] standards.

1.4.7.4 Beryllium

Beryllium (dissolved or total recoverable) was not detected above the method detection limit (0.0001 mg/L) in any of the 64 samples collected in 2018.

1.4.7.5 Boron

Dissolved boron was detected above the method detection limit (0.006 mg/L) in 78 percent of the samples (50 of 64) collected in 2018; concentrations ranged from <0.006-0.079 mg/L.

Total recoverable boron was detected above the method detection limit in 77 percent of the samples (49 of 64) in 2018; concentrations ranged from <0.006-0.082 mg/L.

1.4.7.6 Chromium

Dissolved chromium was detected above the method detection limit (0.0002 mg/L) in 27 percent of the samples (17 of 64) collected in 2018; all concentrations were at or below the 0.0002 mg/L limit.

Total recoverable chromium was detected above the method detection limit in 80 percent of the samples (51 of 64) collected in 2018; concentrations ranged from <0.0002-0.0035 mg/L. No samples had total recoverable chromium concentrations exceeding the DEQ [2017] standard.

1.4.7.7 Cobalt

Dissolved cobalt was detected above the method detection limit (0.00009 mg/L) in 59 percent of the samples (38 of 64) collected in 2018; concentrations ranged from <0.00009-0.00120 mg/L limit.

Total recoverable cobalt was detected above the method detection limit in 77 percent of the samples (49 of 64) collected in 2018; concentrations ranged from <0.00009-0.00140 mg/L. No samples had total recoverable chromium concentrations exceeding the DEQ [2017] standard.

1.4.7.8 Iron

Dissolved iron was detected at concentrations above the method detection limit (0.002 mg/L) in 100 percent of the samples (64 of 64) collected in 2018; concentrations ranged from 0.006-0.42 mg/L.

Total recoverable iron was detected at concentrations above the method detection limit in 100 percent of the samples (64 of 64) in 2018; concentrations ranged from 0.03-4.12 mg/L. Six samples had total recoverable iron concentrations exceeding the DEQ [2017] standard (Table 1-17).

Table 1-17. Total recoverable iron concentrations (mg/L) at Streamside Tailings Operable Unit monitoring stations, 2018.

SS-19	Silver Bow Creek at Frontage Road	1.26	0.93	0.19	0.25

Exceeds the chronic aquatic life standard [DEQ, 2017].

1.4.7.9 Manganese

Dissolved manganese was detected above the method detection limit (0.0003 mg/L) in all 64 samples collected in 2018; concentrations ranged from 0.001-0.300 mg/L.

Total recoverable manganese was detected above the method detection limit in all 64 samples in 2018; concentrations ranged from 0.003-0.352 mg/L.

1.4.7.10 Molybdenum

Dissolved molybdenum was detected at concentrations above the method detection limit (0.00002 mg/L) in 84 percent of the samples (54 of 64) collected in 2018; concentrations ranged from <0.00002-0.006 mg/L.

Total recoverable molybdenum was detected at concentrations above the method detection limit in 86 percent of the samples (55 of 64) in 2018; concentrations ranged from <0.00002-0.006 mg/L.

1.4.7.11 Nickel

Dissolved nickel was detected at concentrations above the method detection limit (0.0002 mg/L) in 75 percent of the samples (48 of 64) collected in 2018; concentrations ranged from <0.0002-0.0018 mg/L.

Total recoverable nickel was detected at concentrations above the method detection limit in 56 percent of the samples (36 of 64) in 2018; concentrations ranged from <0.0002-0.003 mg/L and did not exceed the chronic aquatic life standard [DEQ, 2017].

1.4.7.12 Selenium

Dissolved selenium was detected at concentrations above the method detection limit (0.00005 mg/L) in 80 percent of the samples (51 of 64) collected in 2018; concentrations ranged from <0.00002-0.00086 mg/L.

Total recoverable selenium was detected at concentrations above the method detection limit in 80 percent of the samples (51 of 64) in 2018; concentrations ranged from <0.00005-0.00073 mg/L and did not exceed the chronic aquatic life standard [DEQ, 2017].

1.4.7.13 Silver

Dissolved silver was detected at concentrations above the method detection limit (0.000008 mg/L) in 23 percent of the samples (15 of 64) collected in 2018; concentrations ranged from <0.000008-0.0006 mg/L.

Total recoverable silver was detected at concentrations above the method detection limit in 64 percent of the samples (41 of 64) in 2018; concentrations ranged from <0.000008-0.0002 mg/L and did not exceed the chronic aquatic life standard [DEQ, 2017].

1.4.7.14 Uranium

Dissolved uranium was detected above the method detection limit (0.00001 mg/L) in all 64 samples collected in 2018; concentrations ranged from 0.0003-0.0060 mg/L.

Total recoverable uranium was detected above the method detection limit in all 64 samples in 2018; concentrations ranged from 0.0004-0.0062 mg/L. No samples exceeded the 0.03 mg/L human health surface water standard [DEQ, 2017].

1.4.7.15 Vanadium

Dissolved vanadium was detected above the method detection limit (0.00007 mg/L) in 80 percent of the samples (51 of 64) collected in 2018; concentrations ranged from <0.00007-0.0026 mg/L.

Total recoverable vanadium was detected above the method detection limit in 80 percent of the samples (51 of 64) samples in 2018; concentrations ranged from <0.00007-0.0100 mg/L.

1.4.8 Data Validation

Data quality objectives (DQOs) were evaluated for accuracy and precision. These DQOs were largely met in 2018, with a few exceptions. To assess accuracy, analyte concentrations were measured in field blanks to evaluate sampling accuracy and the extent to which the field techniques may have contaminated the samples. Sixty analytes were analyzed in eight separate field blank samples. Of the 60 analyte concentrations in those field blanks, 2.3 percent (11 of 480) had concentrations equal to or greater than the respective analytical reporting limit. Barium was detected in 25 percent (2 of 8) of the dissolved field blank samples with concentrations of 0.005 mg/L and 0.008 mg/L (RL = 0.003 mg/L). Hardness was detected in 25 percent (2 of 8) of the field blank samples with concentrations of 2 mg/L in each (RL = 1 mg/L). Zinc was detected in 88 percent (7 of 8) of the dissolved field blank samples; detectable dissolved zinc concentrations in field blanks ranged from 0.009-0.030 mg/L (field blank mean = 0.015 mg/L; RL = 0.008 mg/L).

Paired field sample and field duplicate concentrations were compared to evaluate sampling precision. In each pair, sixty analytes were compared in eight separate field sample and field duplicate pairs. In total, there were 480 sample and duplicate pairs and of those 52 percent (248) had concentrations which were at least 500 percent of the analytical reporting limit (RL). Relative percent difference (RPD) comparisons were made between each of those 248 pairs. One pair had an RPD greater than the data quality objective specified for sampling precision (25 percent): the dissolved cadmium sample and duplicate pair collected on March 21, 2018 had an RPD of 30.5 percent.

1.5 DISCUSSION

The SSTOU remedy is intended to remove threats to human health and the environment posed by mining related contaminants within the floodplain of Silver Bow Creek. As of December 2018, major remedial measures have been completed throughout the SSTOU and minor actions were in progress in Subarea 2 to remove residual contaminants. This monitoring report represents a continuing assessment of post-remediation conditions in the SSTOU and at reference sample sites immediately outside the SSTOU.

1.5.1 Streamflows

Streamflows in Silver Bow Creek in 2018 were extremely high throughout the year due to a strong snowpack in the mountains and cool spring weather. High streamflows during the spring and early summer were sustained through the late summer, fall, and early winter of 2018. Streamflows appear to be closely related to some constituent concentrations in the SSTOU, particularly common ion concentrations [RESPEC, 2017a]. However, streamflows have not been a particularly reliable predictor of total recoverable copper concentrations since 2011 [RESPEC, 2017a].

Constituents which appear to be strongly influenced by streamflows include common ions and, to a lesser extent, nutrients. In 2018, hardness, conductivity, and common ion concentrations (alkalinity, bicarbonate alkalinity, calcium, magnesium, sodium, chloride, and sulfate) tended to be lowest during the spring runoff period (Q2) and highest during the late summer sample period (Q3) suggesting that these ion concentrations are strongly influenced by dilution from spring snowmelt. Nutrient concentrations were also generally lowest when streamflows were highest (Q2) indicating that dilution is an important factor controlling nutrient concentrations. However, nutrient concentrations also appeared to be strongly influenced by wastewater management practices and presumably by stream metabolism. Elevated nutrient concentrations during the late fall of 2018 may have been caused by several factors including concentrated nutrients (due to low streamflows), low stream metabolism as rates of biological uptake of nutrients decreased in relation to decreased sunlight and water temperatures, and decomposition of aquatic plants and algae.

Based on a cursory analysis of data collected in the SSTOU from 2011-2016, streamflows were not closely related to total suspended sediment concentrations or total recoverable copper concentrations [RESPEC, 2017a]. Those results suggest that variation in suspended sediment concentration is caused primarily by factors other than streamflow in the SSTOU. A more careful examination of COC concentrations in relation to streamflow and sediment concentrations on a site-by-site basis may be warranted.

1.5.2 Field Parameters

1.5.2.1 Water Temperature

Differences in water temperature among sample quarters reflected seasonal temperature fluctuations in the SSTOU in 2018. Temperatures were lowest in the late fall (Q4) and highest during the spring runoff (Q2). Within sample quarters, variation in water temperature among sites probably did not represent actual temperature variation because comparisons were confounded by the time of day samples were collected and diel variation in water temperatures was likely very strong during some sample periods (particularly Q2 and Q3). During warm periods, diel fluctuations in water temperature were likely primary factors responsible for the variation in temperatures among sites.

This sampling program does not represent mid-summer conditions. Although the temperatures observed in this program during the 2018 sampling periods do not suggest stressful conditions for salmonids and other cold-water organisms, hourly temperature monitoring in Silver Bow Creek by Montana Fish, Wildlife & Parks [RESPEC, 2015] indicate that water temperatures in Silver Bow Creek during the summer commonly exceed 20 C and occasionally exceed 25 C. Therefore, it is important to recognize the limitations of the data included in this report in describing spatial temperature trends.

1.5.2.2 pH

All pH measurements in the SSTOU in 2018 were within the 6.5–9.5 goal range for I-classification streams. Variability in pH between sites during the same sample period were likely the result of diel biogeochemical cycles [Nimmick et al., 2011] and therefore it is difficult to discern spatial pH trends from the data contained in this report.

1.5.2.3 Conductivity

Elevated conductivity may indicate excessive concentrations of dissolved solids which may limit some beneficial uses of water (e.g., irrigation or drinking water). Low conductivity is typically related to watershed geology and may indicate low productivity of associated biological systems. Conductivity tends to be inversely related to streamflow due to dilution.

Conductivity was generally highest at each site in Q3 presumably due to low streamflows at that time. The lowest conductivities were observed in Q2 when streamflows were highest. The greatest increases in conductivity between Silver Bow Creek sites occurred from above the Butte Reduction Works (SS-05A) to above the Butte WWTP (SS-06G) in Q1 and Q3.

1.5.2.4 Dissolved Oxygen

All dissolved oxygen concentrations were above the 1-day minimum standard for an I-classification stream without juvenile salmonids (3 mg/L; DEQ [2017]). Recent studies have

demonstrated that Silver Bow Creek, prior to the Butte WWTP upgrades, had stream reaches with severe hypoxia (dissolved oxygen less than 2 mg/L) during summer nights [Plumb, 2009; Gammons et al., 2011; Naughton, 2013] caused by ammonia-rich effluent from the Butte WWTP [Gammons et al., 2011]. Following the WWTP upgrades, ammonia concentrations are sharply reduced from prior levels although Q1 2018 ammonia levels were elevated.

1.5.2.5 Turbidity and Suspended Sediment

Metals in the SSTOU are complexed with sediments and therefore measurement of sediment concentrations are closely related to total recoverable metal concentrations including COCs. Direct measurement of COC concentrations requires expensive laboratory analysis. Turbidity measurements may provide a simple, cost effective method of estimating suspended sediment and total recoverable COC concentrations by proxy.

1.5.3 Common Ions

Common ions describe the basic water chemistry of the subject water bodies, and certain ions (e.g., sulfate) may be used as indicators for the presence of mine related contaminants. Calcium and magnesium ions contribute to water hardness, which helps to buffer the toxic effects of some heavy metals. Aquatic life toxicity standards for cadmium, copper, lead, zinc and other metals vary as a function of water hardness to account for the mediating effect of hardness on toxicity. Hardness mitigates metal toxicity by preventing aquatic organisms from absorbing metals. Carbonate and bicarbonate alkalinity also contribute to the buffering system of surface waters by resisting changes in pH. Levels of water hardness and alkalinity also influence the productivity of aquatic systems. Western freshwater fisheries typically have alkalinity values of 100–200 mg/L.

In 2018, most ion concentrations increased in stream sections near Butte, specifically between Blacktail Creek (Site SS-01) and Silver Bow Creek above Butte WWTP (Site SS-06G) and downstream of Site SS-06G the rate of increase in common ion concentrations between sites tended to decline. Ion concentrations also tended to be inversely related to streamflow with concentrations generally lowest in Q2 and highest in Q3 or Q4.

1.5.4 Nutrients

The 2016 monitoring year was important for evaluation of nutrient concentrations because upgrades to the Butte WWTP plant became effective during that year. Data from 2018 generally continues to support the conclusion that the 2016 WWTP upgrades have drastically reduced certain nutrient concentrations (particularly ammonia). However, during Q1 2018 ammonia concentrations were elevated suggesting that treatment methods were at least temporarily disrupted.

After the WWTP upgrades, which appear to have become effective between Q1 2016 and Q2 2016, certain nitrogen constituent concentrations have decreased markedly (particularly

ammonia) but other nitrogen constituents (i.e., total nitrogen and nitrate plus nitrite) have decreased, but less dramatically compared to ammonia. Phosphorus concentrations have also decreased since Q1 2016 downstream from the WWTP.

Since the upgrades to the WWTP, ammonia concentrations in Silver Bow Creek below the WWTP (SS-07) have decreased by approximately two orders of magnitude to less than 0.05 mg/L throughout Silver Bow Creek. However, ammonia concentrations in Q1 2018 were high (0.45-1.68 mg/L) at all Silver Bow Creek sites downstream from the WWTP suggesting some disruption or change in treatment processes at the plant during that monitoring period. Total nitrogen and nitrate plus nitrite concentrations in 2018 increased sharply at the WWTP but returned to levels that were similar to, or even lower than, background concentrations. Total nitrogen and nitrate plus nitrite concentrations remain elevated in Silver Bow Creek since the upgrades but concentrations for these nitrogen constituents were relatively low in 2017 and 2018 compared to prior monitoring years. Total phosphorus concentrations were also low in 2017 and 2018 relative to prior monitoring years. However, despite the upgrades, total nitrogen and total phosphorus concentrations remained well above the DEQ standards. For these nutrients, further reductions will likely require non-point source actions above Site SS-01 because concentrations at Site SS-01 for each constituent were well above the DEQ standards. Unlike the nitrogen constituents, total phosphorus concentrations did not increase sharply at the Butte WWTP in 2018 as had occurred during nearly all monitoring periods prior to 2018. These results suggest the WWTP may have improved their ability to control phosphorus loading.

1.5.5 Contaminants of Concern

The SSTOU remedy is intended to remove threats to human health and the environment posed by the presence of metals-rich tailings within the floodplain of Silver Bow Creek. Therefore, most of the results summaries in this report have been allocated to metal COCs.

Performance goals were exceeded for five COCs in 2018 at one or more SSTOU sites: arsenic, copper, lead, mercury, and zinc. Exceedances occurred at three non-SSTOU sites: Blacktail Creek (Site SS-01; arsenic, copper, lead, and mercury), Silver Bow Creek above Butte Reduction Works (Site SS-05A; arsenic, copper, lead, and mercury) and Silver Bow Creek above Butte WWTP (Site SS-06G; arsenic, and copper). At SSTOU sites, 48 samples were collected and the performance goals were exceeded for arsenic in 19 (40 percent) samples, for copper in 33 (69 percent) samples, for lead in 2 (4 percent) samples, for mercury in 20 (42 percent) samples, and for zinc in 2 (4 percent) samples. Cadmium did not exceed the performance goal at any SSTOU site.

Suspended sediment concentrations and total recoverable COC concentrations appear to be strongly linked in the SSTOU [RESPEC, 2017a]. In 2016 and 2017, suspended sediment concentrations tended to be highest during the winter (Q4) in the SSTOU and total recoverable COC concentrations were also elevated during those periods. However, in 2018, suspended sediment concentrations were highest at Site SS-01 in Q1 and at most sites in Q1 and Q2. During those quarters of 2018, total recoverable COC concentrations also were elevated accordingly.

Major remediation was completed in Subarea 1 in 2003, in Subarea 2 in 2010, in Subarea 3 in 2015, and in Subarea 4 in 2014. Therefore, it is most likely that changes in COC concentrations over time would be most apparent in recent data (since 2010) in the Subarea 3 and 4 sites. From 2010-2018, COC concentrations appear to have stabilized in Subarea 1 and 2 making trends difficult to discern without applying statistical analyses. However, Subarea 3 sites above (SS-15A-2) and below (SS-15B) German Gulch appear to have declined in most COC concentrations through time. In Subarea 4, Opportunity (SS-17D) has demonstrated a sharp decline in COC concentrations since 2010. Additional cleanup actions in Subareas 1 and 2, which were recently completed in Subarea 1 and in progress in Subarea 2, may result in some punctuated decreases in COC concentrations.

1.5.6 Other Metals

No surface water samples exceeded DEQ [2017] standards for any non-COC metals with the exception of iron. Iron concentrations exceeded the standard in 6 of 64 samples. As with the COCs, elevated iron concentrations appeared to correspond to elevated turbidity and suspended sediment concentrations.

1.5.7 Data Validation

All data derived from laboratory analysis of surface water were validated through field and laboratory quality control procedures. A quality assurance and quality control checklist, field duplicate and blank results, and assessments of data quality objectives are included in Appendix A.

Few detections of any analytes in field blanks suggest the field techniques generally introduced little contamination into the samples. However, one exception was dissolved zinc which was detected in 88 percent of the field blank samples, although at low concentrations (not more than 0.030 mg/L) relative to the performance goal (0.120 mg/L at water hardness of 100 mg/L). The consistency with which the field blanks were contaminated by dissolved zinc suggests the sample processing technique introduces zinc into the dissolved samples resulting in a positive bias to dissolved samples (i.e., actual dissolved zinc concentrations in the stream were probably slightly lower than the concentrations reported in the field blank samples). We suspect the disposable membrane discs used to filter the samples were likely responsible for the zinc contamination despite rinsing each filter with one syringe volume (60 mL) of deionized water and one volume of sample water prior to filtration of each sample. Although contamination of dissolved zinc is a concern, the performance goal for zinc is based on total recoverable (i.e., unfiltered) concentrations and therefore contamination of the total recoverable samples by the filter membranes would not have occurred. No field blanks had total recoverable zinc concentrations above the reporting limit suggesting contamination of those samples was minimal.

The exceedance rate of the project data quality objective for sampling precision (i.e., paired sample and duplicate RPDs were less than 25 percent) was less than one percent in 2018 suggesting sampling precision for the data collected was high.

2.0 SEDIMENT

2.1 INTRODUCTION

The Streamside Tailings Operable Unit (SSTOU) Record of Decision (ROD) did not specify numeric remediation standards for concentrations of contaminants of concern in instream sediment, stating "No metals concentration cleanup goal is established by this action" [DEQ and USEPA, 1995]. The 1998 Explanation of Significant Differences (ESD) [DEQ and USEPA, 1998] modified the sediment goals to recognize that the realignment and reconstruction of the stream channel in many areas provided for the streambed to be reconstructed with clean materials. In those areas where the existing channel was to be maintained, the sediments would be excavated to a minimum depth of one foot and the new channel bed reconstructed with clean fill material. Thus, the contaminated sediments were replaced with clean material throughout the operable unit.

2.2 REFERENCE VALUES

Contaminant of concern concentrations in instream sediments are compared to ecological reference values to evaluate the influence of remediation and extent of recontamination from upstream on sediment. These reference values are the "threshold effect concentration" (TEC) and the "probable effect concentration" (PEC) which are consensus-based sediment quality guidelines for benthic organisms [MacDonald et al., 2000]. At metal COC concentrations above the TEC, benthic organisms may be affected. At metal COC concentrations above the PEC, benthic organisms are likely to be affected (Table 2-1).

Table 2-1. Reference values for contaminant of concern concentrations (dry weight [DW]) of instream sediments in the Streamside Tailings Operable Unit. The threshold effect concentration (TEC) and probable effect concentration (PEC) were described in MacDonald et al. [2000].

Contaminant of Concern	Threshold Effect Concentration (mg/kg-DW)	Probable Effect Concentration (mg/kg-DW)
Arsenic	9.79	33
Cadmium	0.99	4.98
Copper	31.6	149
Lead	35.8	128
Mercury	0.18	1.06
Zinc	121	459

2.3 METHODS

The purpose of the instream sediment monitoring program is to collect data describing the temporal and spatial variation of COC concentrations in the SSTOU. These data provide a long-term record of environmental conditions in the SSTOU. This long-term record provides a dataset to evaluate the effect of remediation on environmental conditions in the SSTOU over time. Changes to the sediment monitoring program have occurred over time and a record of these changes is provided in the project sampling and analysis plan [RESPEC, 2018b]. The program attempts to fully adhere to monitoring requirements specified in the SSTOU ROD (Table 2-2).

Table 2-2. Minimum post-remedy instream sediment monitoring requirements specified in the Record of Decision for the Streamside Tailings Operable Unit [DEQ and USEPA, 1995].

Locations/Physical	Analytical Parameters	Analytes
Surface water locations and at each depositional area.	Metals (total) in three size fractions: <0.063 mm, 0.065-1 mm, >1 mm and greater	Arsenic, cadmium, copper, lead, mercury, zinc

2.3.1 Monitoring Locations

In 2018, major remedial actions were completed throughout the SSTOU. Monitoring was conducted at 16 long-term monitoring sites and three additional sites which were monitored to investigate specific questions (Figure 2-1). The three additional sites (Sites SS-04, SLAG-01, and SS-15A-2) are not intended to be long-term sites.

Of the long-term sites, 12 were located within the SSTOU (Table 2-3; Figure 2-1). Locations of some sampling sites were selected based on SSTOU ROD requirements (Table 2-2). Long-term monitoring sites located outside the SSTOU were sampled to describe instream sediment conditions in portions of Silver Bow Creek and Blacktail Creek immediately upstream from the SSTOU (Sites SS-01, SS-05A, and SS-06G), and in a major tributary (German Gulch) entering Silver Bow Creek within the SSTOU (Site SS-15G) (Figure 2-1). Site SS-05A is located within Lower Area One of the Butte Priority Soils Operable Unit and historically was heavily contaminated by mining and smelting waste. Therefore, Site SS-05A is not representative of background conditions. Blacktail Creek at Father Sheehan Park (Site SS-01) and German Gulch (Site SS-15G) probably best represent "background" conditions outside the direct influence of mining contamination from Butte area operations.

Three short-term sites were monitored starting in 2016: an alternate Silver Bow Creek above German Gulch (Site SS-15A-2), Silver Bow Creek in Slag Canyon (SLAG-01), and Blacktail Creek at Metro Storm Drain confluence (Site SS-04). Site SS-15A-2 was sampled to investigate if COC concentrations at Site SS-15A, where the streambed was not remediated, differed substantially from a site approximately 200 m upstream where the streambed was remediated (Figure 2-2). Short-term Sites SLAG-01 and Site SS-04, both located upstream from the SSTOU, were added to the sediment monitoring network in 2016 at the request of the Natural Resource Damage

Program to provide additional data for Silver Bow Creek and Blacktail Creek in the vicinity of the Slag Canyon and Metro Storm Drain (Figure 2-3).

Table 2-3. Instream sediment sampling locations in the Streamside Tailings Operable Unit.

Site ID	Site Location	Within SSTOU	Long-term Site	Location (GPS coordinates, NAD 83)	
				Latitude	Longitude
SS-01	Blacktail Creek at Father Sheehan Park		x	45.98532	-112.50772
SS-04[35]	Blacktail Creek at Metro Storm Drain Confluence			45.99460	-112.53592
SLAG-01	Silver Bow Creek in Slag Canyon			45.99675	-112.54143
SS-05A	Silver Bow Creek above Butte Reduction Works		x	45.99653	-112.54343
SS-06G	Silver Bow Creek above Butte WWTP	x	x	45.99648	-112.56316

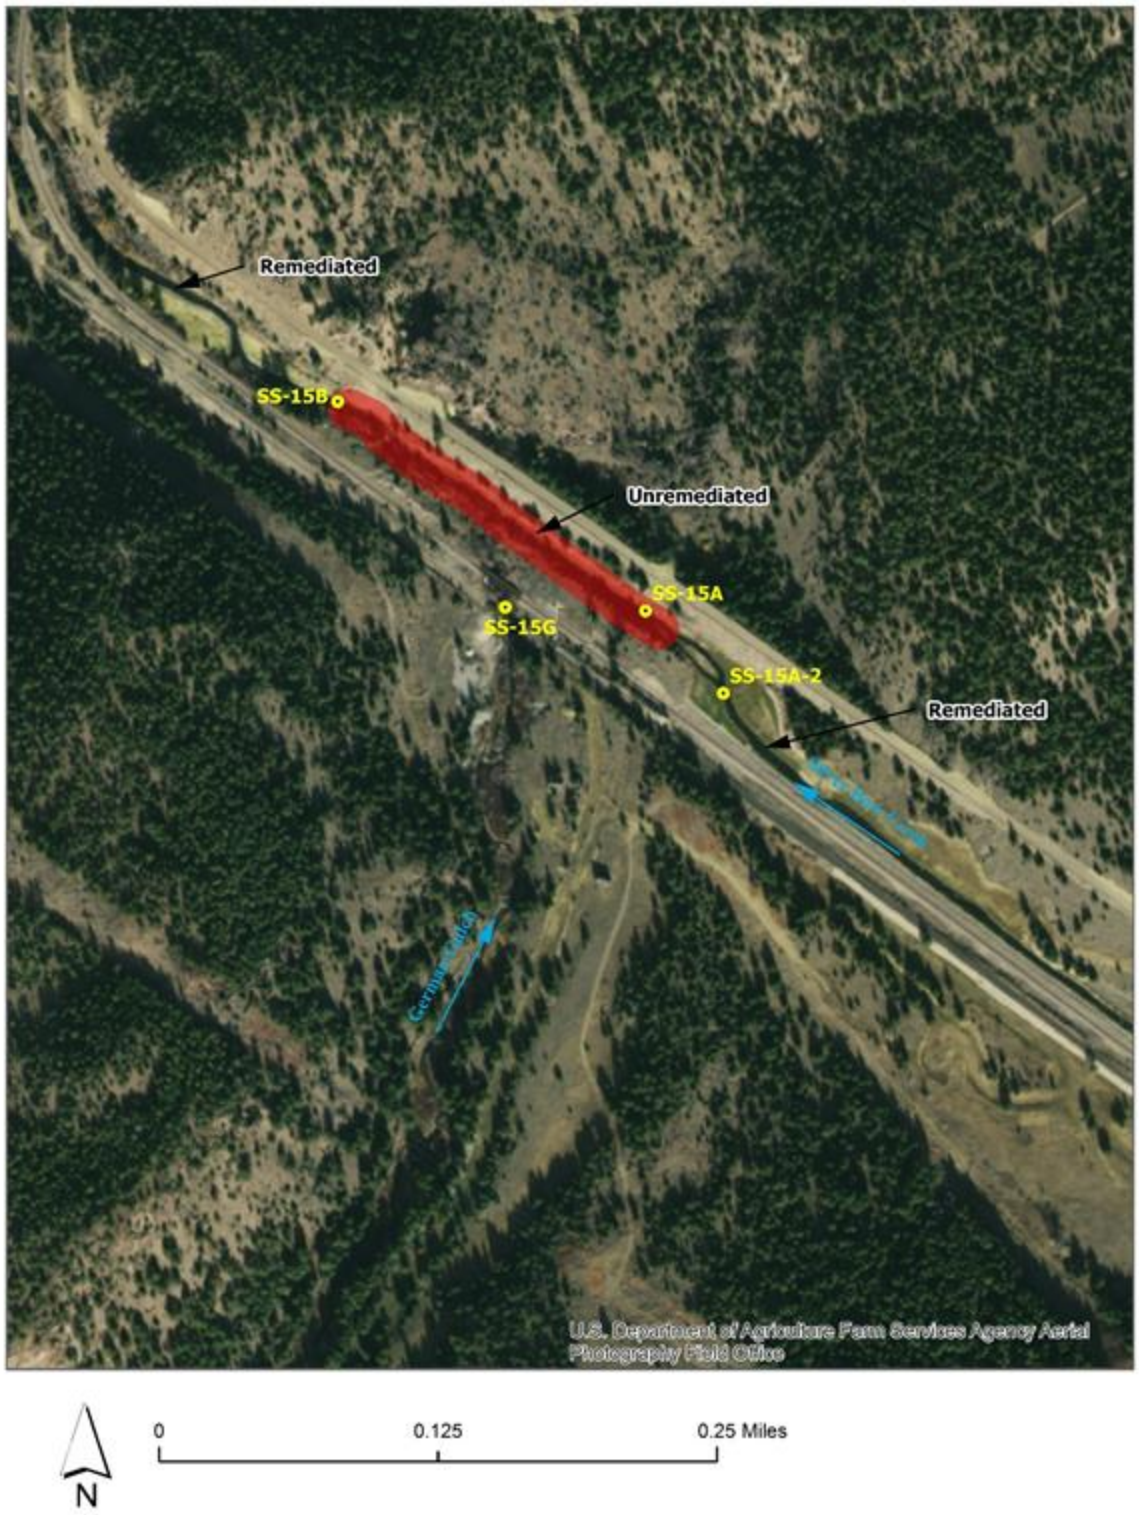

Figure 2-2. Instream sediment sampling locations in the vicinity of the German Gulch confluence in the Streamside Tailings Operable Unit. The reach of the Silver Bow Creek stream channel highlighted in red was not remediated due to limited access and the relatively low estimated tailings volume.

Figure 2-3. Silver Bow Creek and Blacktail Creek instream sediment sampling locations in the vicinity of the Slag Canyon (highlighted in yellow) and the Metro Storm Drain (i.e., Silver Bow Creek) and Blacktail Creek confluence in Butte, Montana.

2.3.2 Monitoring Schedule

Monitoring events were scheduled to describe seasonal variation in sediment chemistry within the SSTOU. One monitoring event occurred during each calendar quarter. Quarterly monitoring events occurred near the end of each quarter. First quarter (Q1) monitoring occurred from March 21-22 prior to spring snowmelt runoff. Second quarter (Q2) monitoring occurred from June 6-7 approximately at the peak of the spring snowmelt runoff period. Third quarter (Q3) monitoring occurred from September 12-13 during low streamflow conditions. Fourth quarter (Q4) monitoring occurred from November 28-29 during late fall.

Monitoring at Site SS-10B (Silver Bow Creek below Sand Creek) was discontinued in 2017. Site SS-10B was paired with Site SS-10A (Silver Bow Creek above Sand Creek) to elicit sediment chemistry contributions from Sand Creek. After several years of data collection, Site SS-10B showed no significant differences from Site SS-10A and therefore continued monitoring provided little insight.

2.3.3 Monitoring Parameters

Instream sediment samples were analyzed for total extractable dry weight concentrations of COCs (arsenic, cadmium, copper, lead, mercury, and zinc) and other metals (aluminum, antimony, barium, beryllium, boron, chromium, cobalt, iron, manganese, molybdenum, nickel, selenium, silver, uranium, and vanadium). Each sample was sieved in the laboratory into three size fractions (<0.063 mm, 0.063–1 mm, and 1–2 mm) and metal concentrations were determined independently for each size fraction.

2.3.4 Sample Collection and Analysis

Sample collection and analysis procedures are described in the project sampling and analysis plan (SAP) [RESPEC, 2018b] and quality assurance and quality control procedures are described in the program quality assurance project plan (QAPP) [RESPEC, 2014]. Sample collection methods generally followed standard operating procedures (SOPs) developed for the Clark Fork River [AR, 1992]. Composite sediment samples were collected from at least five depositional areas in the stream according to Montana Department of Environmental Quality (DEQ) standard operating procedures (SOPs) [DEQ, 2012a]. Each composite sample was wet sieved in the laboratory into three sediment size fractions: <0.063 mm, 0.063–1 mm, and 1–2 mm. Samples were analyzed by size fraction at Energy Laboratories (Helena, Montana). Laboratory analysis procedures included SW6010B, SW6020, SW7471A, or SW7471B (Table 2-4). Samples collected from Sites SS-04 and SLAG-01 were not analyzed for the entire suite of analytes listed in Table 2-4. At those sites, samples were analyzed for arsenic, cadmium, copper, lead, and zinc in the <0.063 mm size fraction following the same analytical procedures.

Table 2-4. Analytes and analytical methods for instream sediment monitoring in the Streamside Tailings Operable Unit, 2018.

Parameter	Category	Analytical Method
Arsenic	Contaminants of concern	SW6010B
Cadmium		SW6020
Copper		SW6010B
Lead		SW6010B
Zinc		SW6010B
Mercury		SW7471B
Aluminum	Other metals	SW6010B
Antimony		SW60120
Barium		SW6010B
Beryllium		SW6010B
Boron		SW6010B
Chromium		SW6010B
Cobalt		SW6010B
Iron		SW6010B
Manganese		SW6010B
Molybdenum		SW6020
Nickel		SW6010B
Selenium		SW6020
Silver		SW6020
Uranium		SW6020
Vanadium		SW6010B

2.3.5 Data Analysis

Data analysis includes description of spatial trends (among sample sites during the same sample period) and temporal (quarterly and annual) trends in constituent concentrations. For COC, longer-term (since 2014) results are included to provide context for the 2018 results and to evaluate concentrations through time.

Analyte concentrations for each sample were compared to reference values identified for the SSTOU (Table 2-1). The weighted mean concentration of the three sediment size fractions (<0.063 mm, 0.065-1 mm, 1-2 mm) was used for comparison to the identified reference values. The weighted mean concentrations were computed for each COC metal on the basis of sample fraction weight among the three size fractions. In addition, all samples collected at each site were grouped and the median concentration of each COC in the finest size fraction (<0.063 mm) were compared using boxplots to evaluate general spatial trends.

2.3.6 Data Validation

Data quality objectives (DQOs) were established in the SSTOU QAPP for "data representativeness", "comparability", "completeness", "sensitivity", "precision", "bias", and "accuracy" [RESPEC, 2014]. Methods for field and laboratory QA/QC procedures are also described in detail in the project QAPP. A completed QA/QC checklist, summary tables of field

duplicate and field blank results, and assessments of data quality objectives are included in Appendix A. Results from the analytical laboratory are included in Appendix B.

Variability in sediment metals concentrations among samples was assessed by comparing field duplicate samples to field samples. Field duplicate samples were collected at the same location and at the same time as field samples and were processed and analyzed by the same methods. The relative percent difference (RPD) between the concentration in the field duplicate and field sample pair was determined for each metal. Two field duplicate samples were collected during each sampling event and RPD statistics were calculated for each field duplicate and field sample pair.

2.4 RESULTS

2.4.1 Sample Size Fraction

The proportion of sediment by size fraction in each sample is displayed in Table 2-5.

Table 2-5. Proportion of each sediment sample in three size fractions in the Streamside Tailings Operable Unit, 2018.

Site	Site Location	Sample Quarter (%)			
		Q1	Q2	Q3	Q4
Fine fraction (<0.063 mm)					
SS-01	Blacktail Creek at Father Sheehan Park	4.5	5.1	2.5	1.6

--- Not sampled.

2.4.2 Contaminants of Concern

2.4.2.1 Arsenic

Among all samples collected in 2018, sediment arsenic concentrations ranged from 25-413 mg/kg-DW in the <0.063 mm size fraction, from 4.1-113 mg/kg-DW in the 0.063-1 mm size fraction, and from <0.2-154 mg/kg-DW in the 1-2 mm size fraction (Table 2-6). Weighted mean arsenic concentrations ranged from 2-80 mg/kg-DW among samples with arsenic concentrations above the reporting limit in all three size fractions (Table 2-7). Based on the weighted mean concentrations, exceedances of the arsenic TEC occurred in 51 samples and the PEC was exceeded in 6 samples; weighted mean concentrations were not determined for three samples because one or more size fractions for that sample had arsenic concentration below the analytical reporting limit and therefore weighted mean concentrations could not be determined (Table 2-7).

Spatially, fine fraction (<0.063 mm) median arsenic concentrations generally increased between each site from Blacktail Creek at Father Sheehan Park (Site SS-01) downstream to Silver Bow Creek above the Butte Reduction Works (Site SS-05A) then decreased downstream to Silver Bow Creek above Sand Creek (Site SS-10A) (Figure 2-4). Downstream from Site SS-10A, median concentrations were generally similar at each site with the exception of Silver Bow Creek below German Gulch (Site SS-15B) (Figure 2-4). Median concentration in Silver Bow Creek below German Gulch (Site SS-15B) were similar to the median concentration at Site SS-08 (Figure 2-4). The median concentration at Site SS-05A was higher than at any other site (Figure 2-4).

In "background" sites (i.e., Sites SS-01 and SS-15G), fine fraction (<0.063 mm) median arsenic concentrations were above the PEC in both sites (Figure 2-4). In Subarea 1 and 2, median concentrations were well above background concentrations in Silver Bow Creek sites below the Butte WWTP (Site SS-07) and at Rocker (Site SS-08) but similar to background in all other Subarea 1 and 2 sites (Sites SS-10A, SS-11C, SS-11D, SS-13, and SS-14) (Figure 2-4). In Subarea 3, the median concentration at Site SS-15A-2 was similar to the background sites but below German Gulch (Site SS-15B) median concentrations were higher than background (Figure 2-4). Subarea 4 sites (Sites SS-16B, SS-17D, and SS-19) had median concentrations approximately 1-1.5 times higher than background (Figure 2-4).

Since 2014, arsenic concentrations were relatively constant and were generally at or slightly above the PEC at background sites in Blacktail Creek (Site SS-01) and German Gulch (Site SS-15G) (Figure 2-5). None of the reference sites (Sites SS-04, SLAG-01, SS-05A, and SS-06G) demonstrated clear directional (i.e., monotonic) trends although some sites appear to demonstrate slight increasing trends (Figure 2-5). In Subarea 1, concentrations in Silver Bow Creek below the Butte WWTP (Site SS-07) appears to demonstrate a slight increasing trend, particularly since 2017, but no clear trends are apparent in other Subarea 1 sites (Figure 2-6). In Subareas 2 and 3, concentrations appear generally stable through time and no positive or negative trends are apparent (Figure 2-7; Figure 2-8). Concentrations in Silver Bow Creek below German Gulch (Site SS-15B) have been highly variable compared to other Subarea 2 and 3 sites (Figure 2-7; Figure 2-8). In Subarea 4, concentrations at the Silver Bow Creek sites at Fairmont (Site SS-16B) and

Opportunity (Site SS-17D) appear to be decreasing slightly through time (Figure 2-9). No temporal trend is apparent at the Frontage Road site (Site SS-19), primarily due to the high degree of variability in the results (Figure 2-9).

Exceeds the threshold effect concentration [MacDonald et al., 2000].

Exceeds the probable effect concentration [MacDonald et al., 2000].

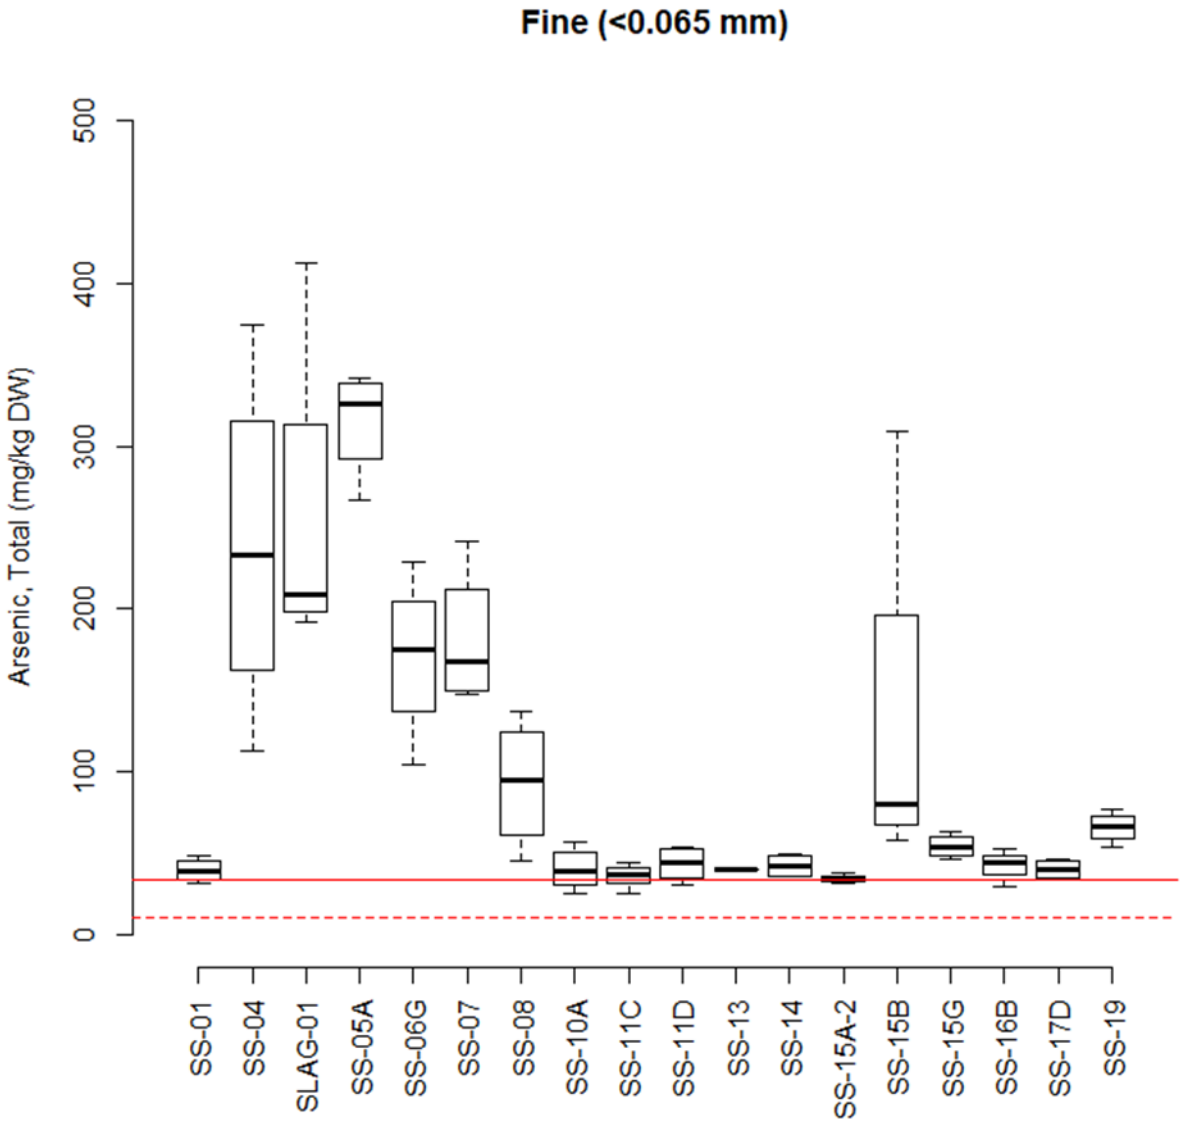

Figure 2-4. Total arsenic concentrations in instream sediment (<0.063 mm) samples collected at Streamside Tailings Operable Unit monitoring stations, 2018. Solid red line is the 33 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 9.79 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

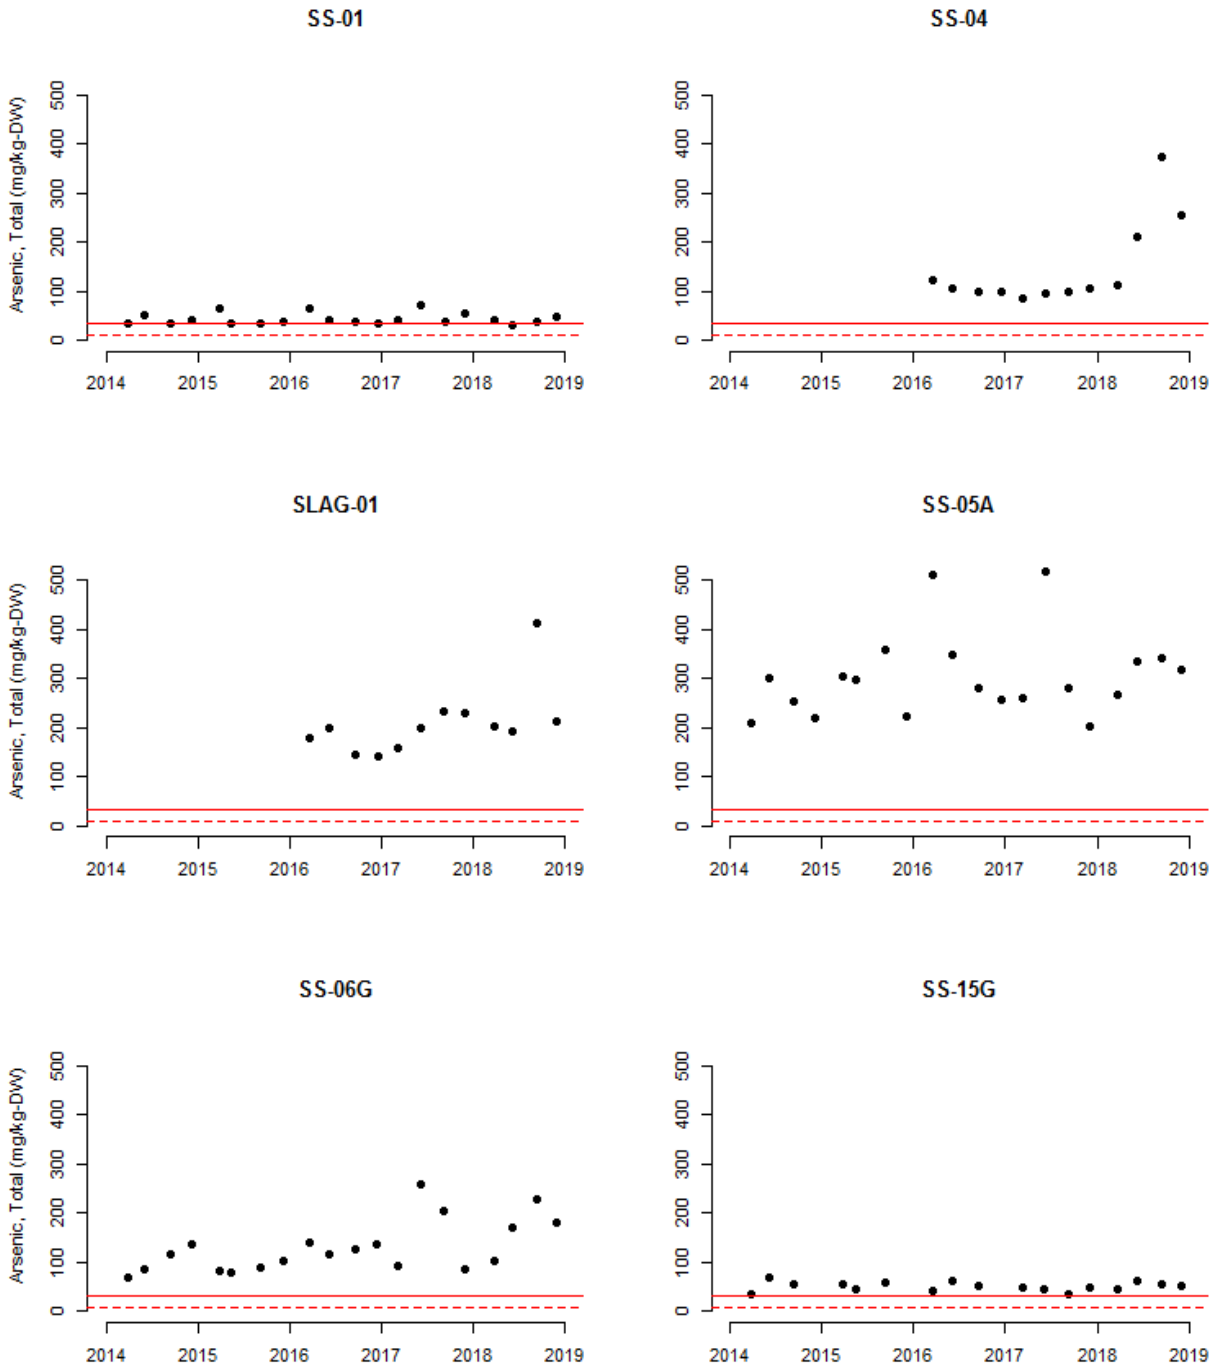

Figure 2-5. Fine fraction (<0.063 mm) total dry-weight arsenic concentrations (mg/kg-DW) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Blacktail Creek at Metro Storm Drain Confluence (Site SS-04), Silver Bow Creek in Slag Canyon (SLAG-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Solid red line is the 33 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 9.79 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

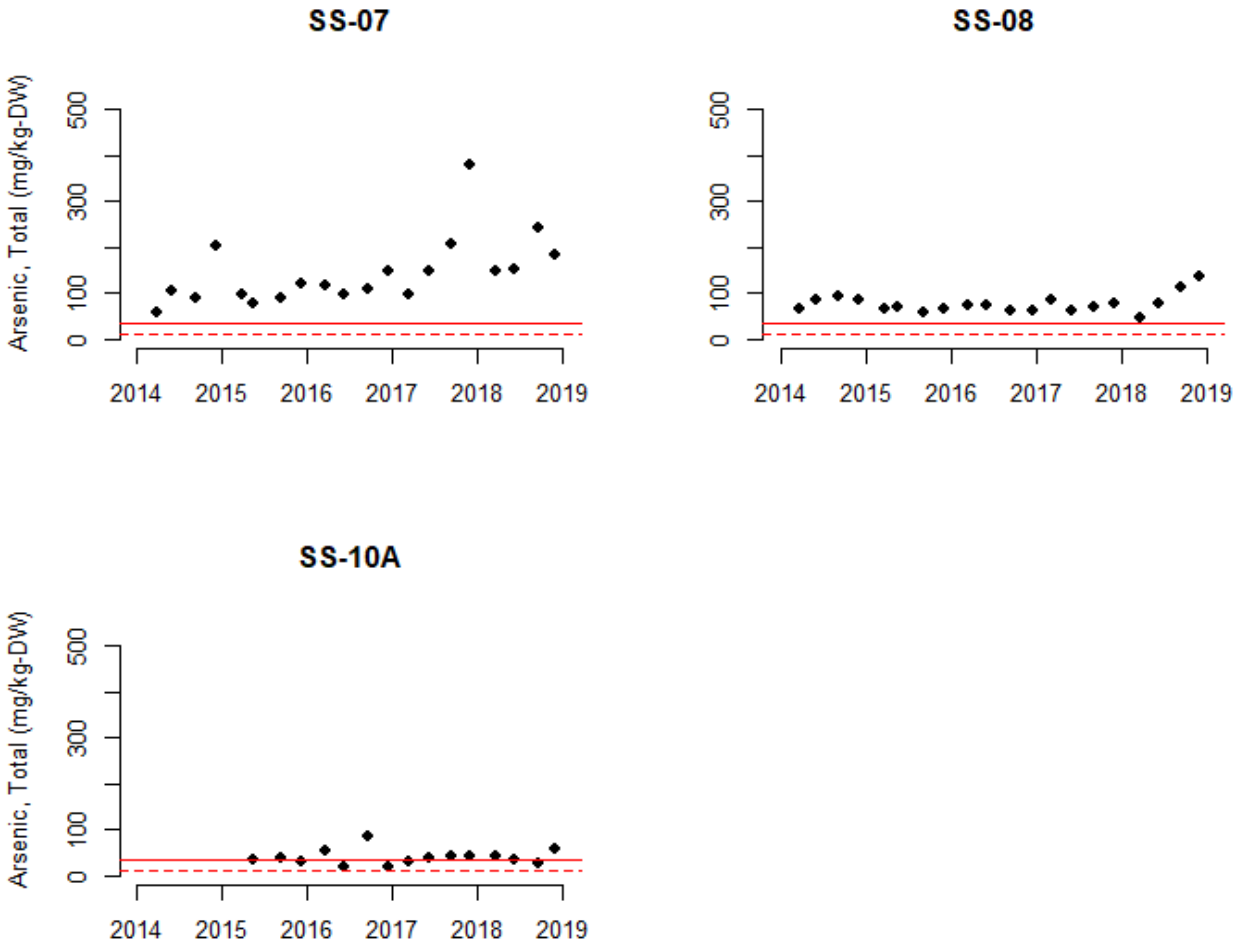

Figure 2-6. Fine fraction (<0.063 mm) total dry-weight arsenic concentrations (mg/kg-DW) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Solid red line is the 33 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 9.79 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

Figure 2-7. Fine fraction (<0.063 mm) total dry-weight arsenic concentrations (mg/kg-DW) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Solid red line is the 33 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 9.79 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

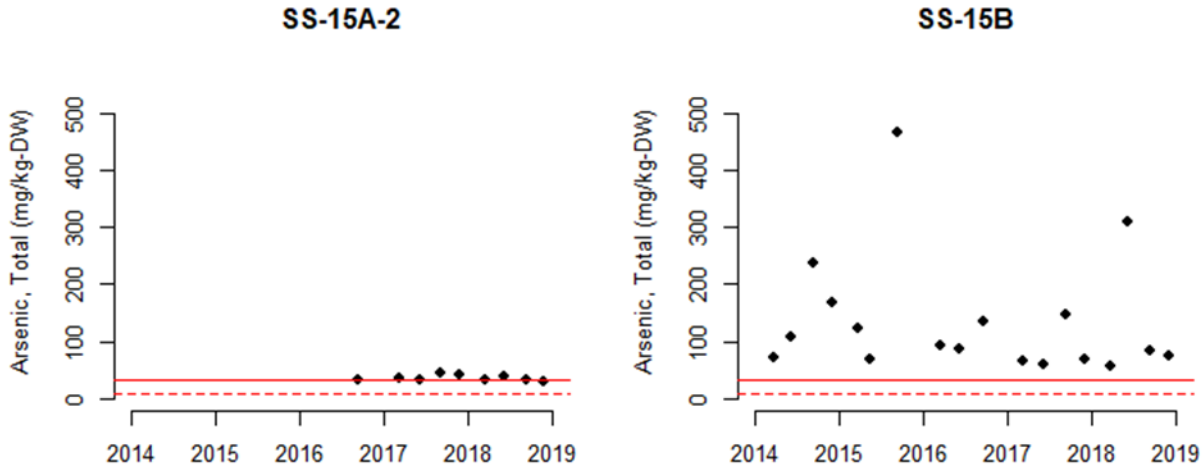

Figure 2-8. Fine fraction (<0.063 mm) total dry-weight arsenic concentrations (mg/kg-DW) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above German Gulch (Alternate Site, Site SS-15A-2), Silver Bow Creek above (Site SS-15A) and below (Site SS-15B) German Gulch. Solid red line is the 33 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 9.79 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

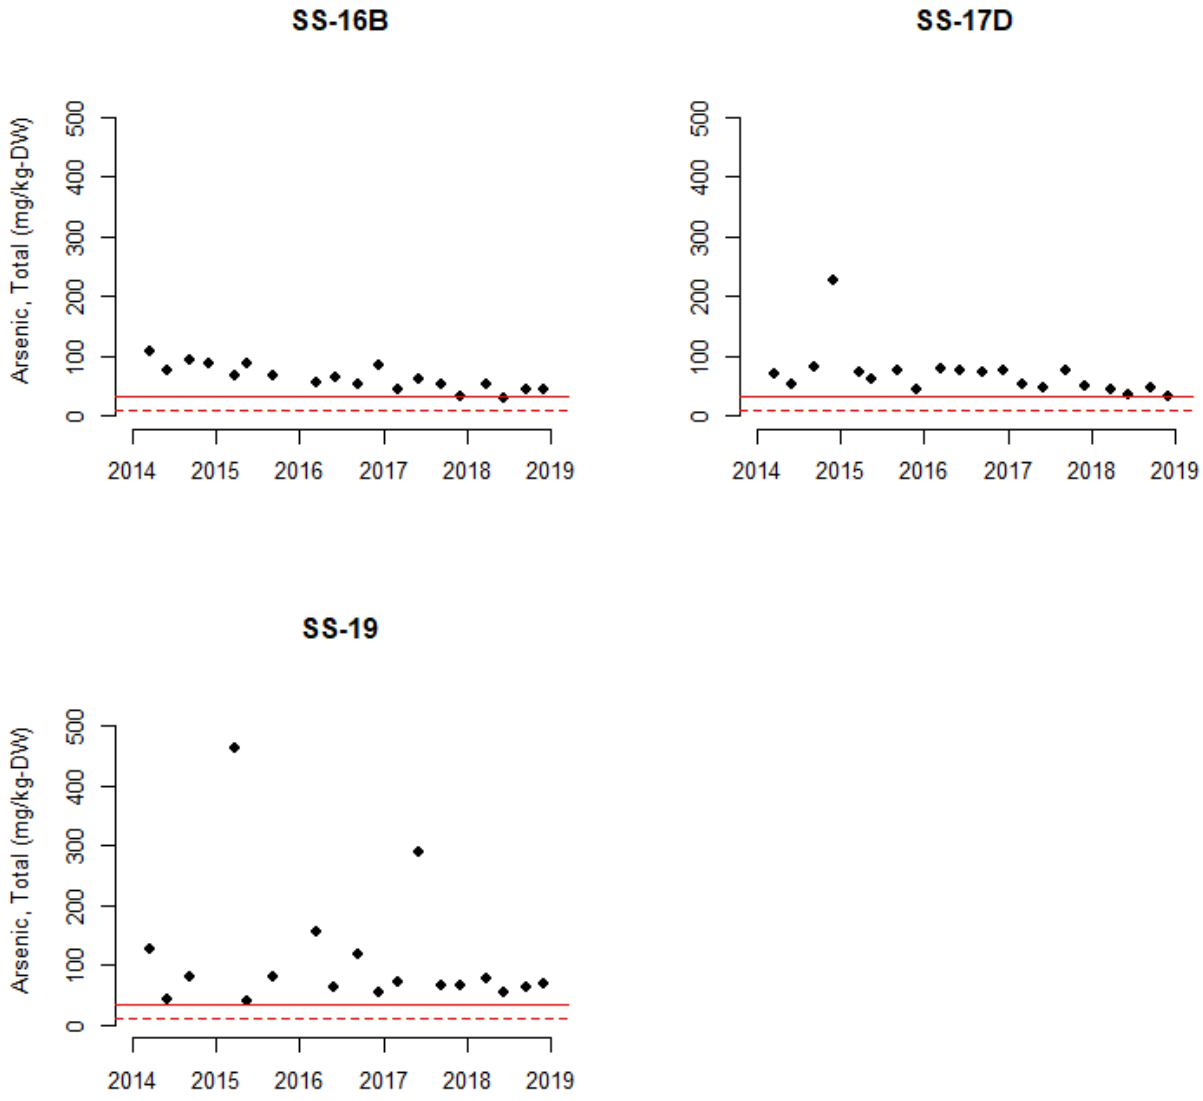

Figure 2-9. Fine fraction (<0.063 mm) total dry-weight arsenic concentrations (mg/kg-DW) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Solid red line is the 33 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 9.79 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

2.4.2.2 Cadmium

Among all samples collected in 2018, sediment cadmium concentrations ranged from 0.9-70.2 mg/kg-DW in the <0.063 mm size fraction, from <0.1-6.2 mg/kg-DW in the 0.065-1 mm size fraction, and from <0.1-2.7 mg/kg-DW in the 1-2 mm size fraction (Table 2-8). Weighted mean concentrations ranged from 0.15-4.43 mg/kg-DW among samples with concentrations above the reporting limit in all three size fractions (Table 2-9). Based on the weighted mean concentrations, exceedances of the TEC occurred in 24 samples and the PEC was exceeded in 0 sample; weighted mean concentrations were not determined for 15 samples because one or more size fractions for that sample had a concentration below the analytical reporting limit and therefore weighted mean concentrations could not be determined (Table 2-9).

Spatially, fine fraction (<0.063 mm) median cadmium concentrations generally increased between each site from Blacktail Creek at Father Sheehan Park (Site SS-01) downstream to Silver Bow Creek in Slag Canyon (SLAG-01) and then generally decreased downstream throughout the SSTOU with some local deviations (Figure 2-10). Silver Bow Creek at Frontage Road (Site SS-19) had a median concentration slightly higher than expected given the prevailing trend (Figure 2-10) and also had a Q3 concentration that was well above any other sample concentrations in 2018 (70.2 mg/kg) (Table 2-8).

In "background" sites (i.e., Sites SS-01 and SS-15G), fine fraction (<0.063 mm) median cadmium concentrations were similar and were between the TEC and PEC (Figure 2-10). Median concentrations in all SSTOU sites were well above background and were generally above the PEC (Fiugre 2-10).

Since 2014, cadmium concentrations were relatively constant and were generally at or slightly above the TEC at background sites in Blacktail Creek (Site SS-01) and German Gulch (Site SS-15G) (Figure 2-11). Some reference sites (Sites SS-04, SLAG-01, and SS-06G) appear to demonstrate slight increasing trends through time (Figure 2-11). In Subareas 1 and 2, concentrations appear generally stable through time and no positive or negative trends are apparent (Figure 2-12; Figure 2-13). In Subarea 3, concentrations appear generally stable through time although the limited data set at the relocated site above German Gulch (Site SS-15A-2) suggests a decreasing trend through time (Figure 2-14). In Subarea 4, no clear temporal trends were apparent, primarily due to the high degree of variability at these sites (Figure 2-15).

Table 2-8. Total cadmium concentrations (mg/kg dry weight) by size fraction in quarterly instream sediment samples from Streamside Tailings Operable Unit monitoring stations, 2018.

DNA Does not apply because one or more sample fractions had ND concentration.

Exceeds the threshold effect concentration [MacDonald et al., 2000].

Exceeds the probable effect concentration [MacDonald et al., 2000].

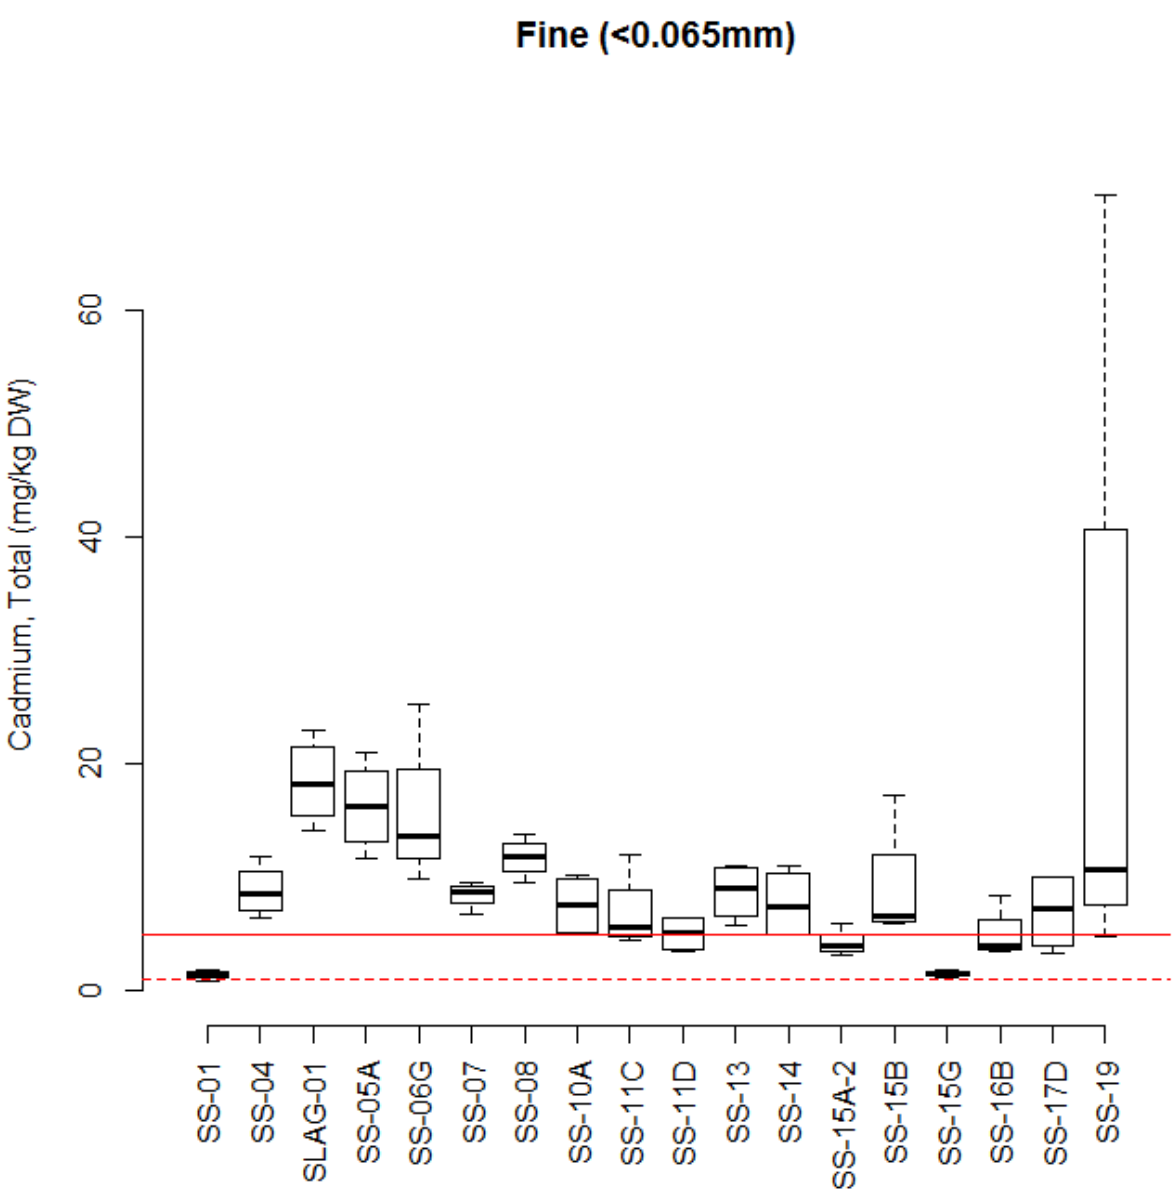

Figure 2-10. Total cadmium concentrations in instream sediment (<0.063 mm) samples collected at Streamside Tailings Operable Unit monitoring stations, 2018. Solid red line is the 4.98 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.99 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

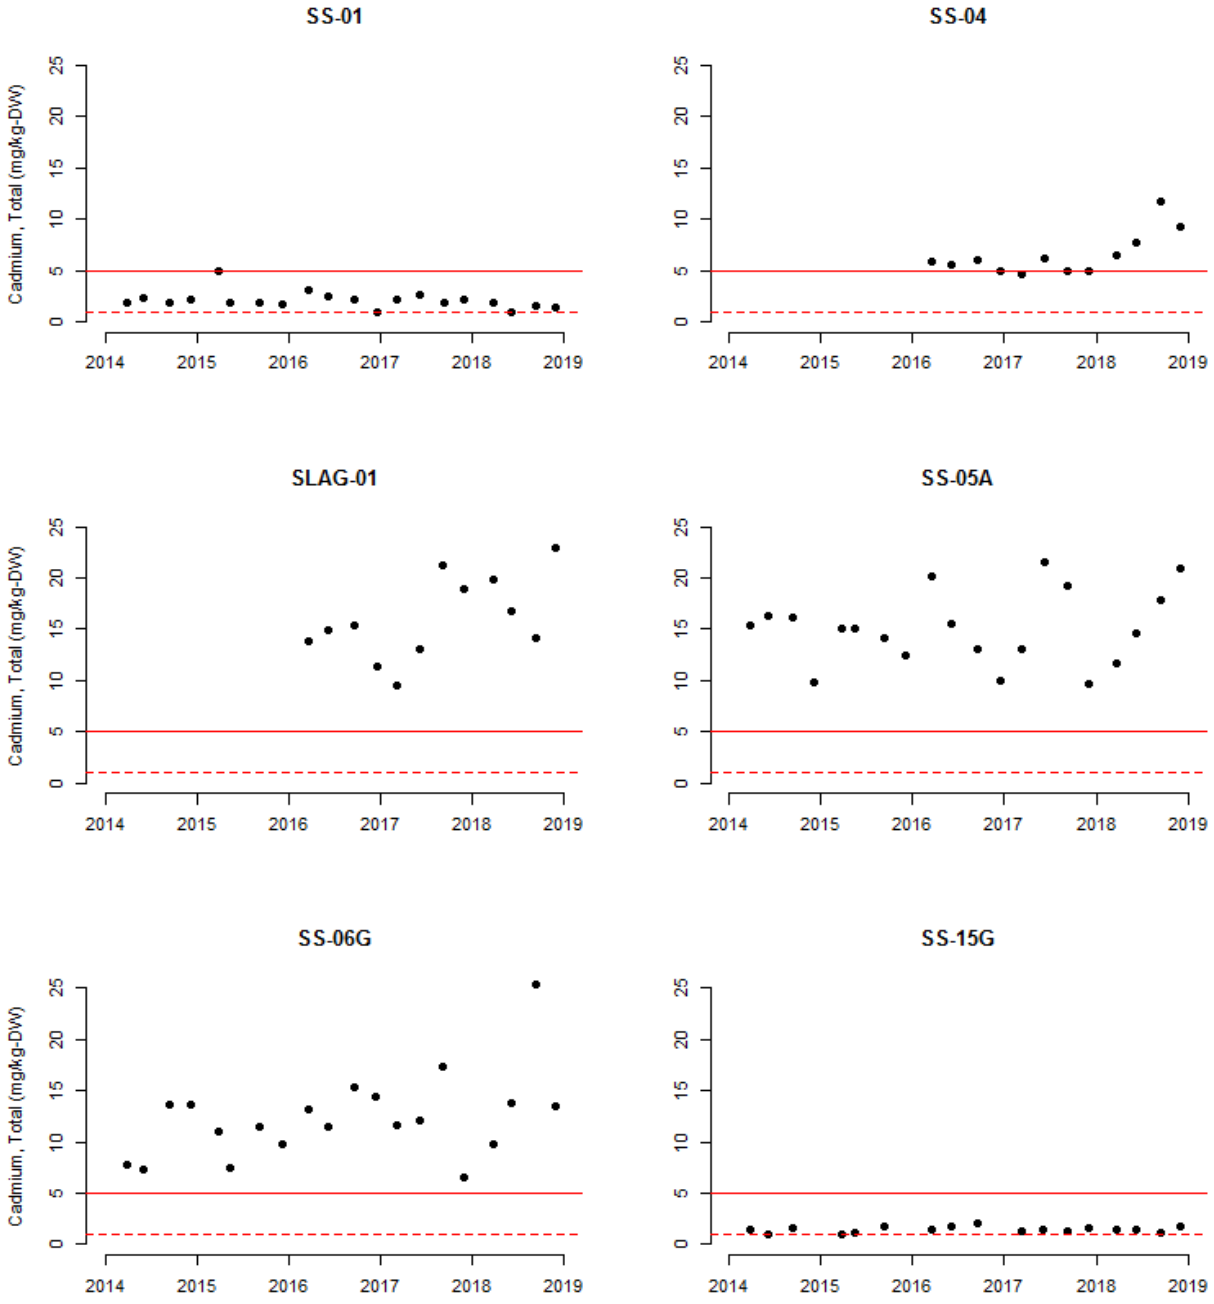

Figure 2-11. Fine fraction (<0.063 mm) total dry-weight cadmium concentrations (mg/kg-DW) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Blacktail Creek at Metro Storm Drain Confluence (Site SS-04), Silver Bow Creek in Slag Canyon (SLAG-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Solid red line is the 4.98 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.99 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000]. Samples with concentrations below the analytical reporting limit (RL) are represented with concentrations at half the RL.

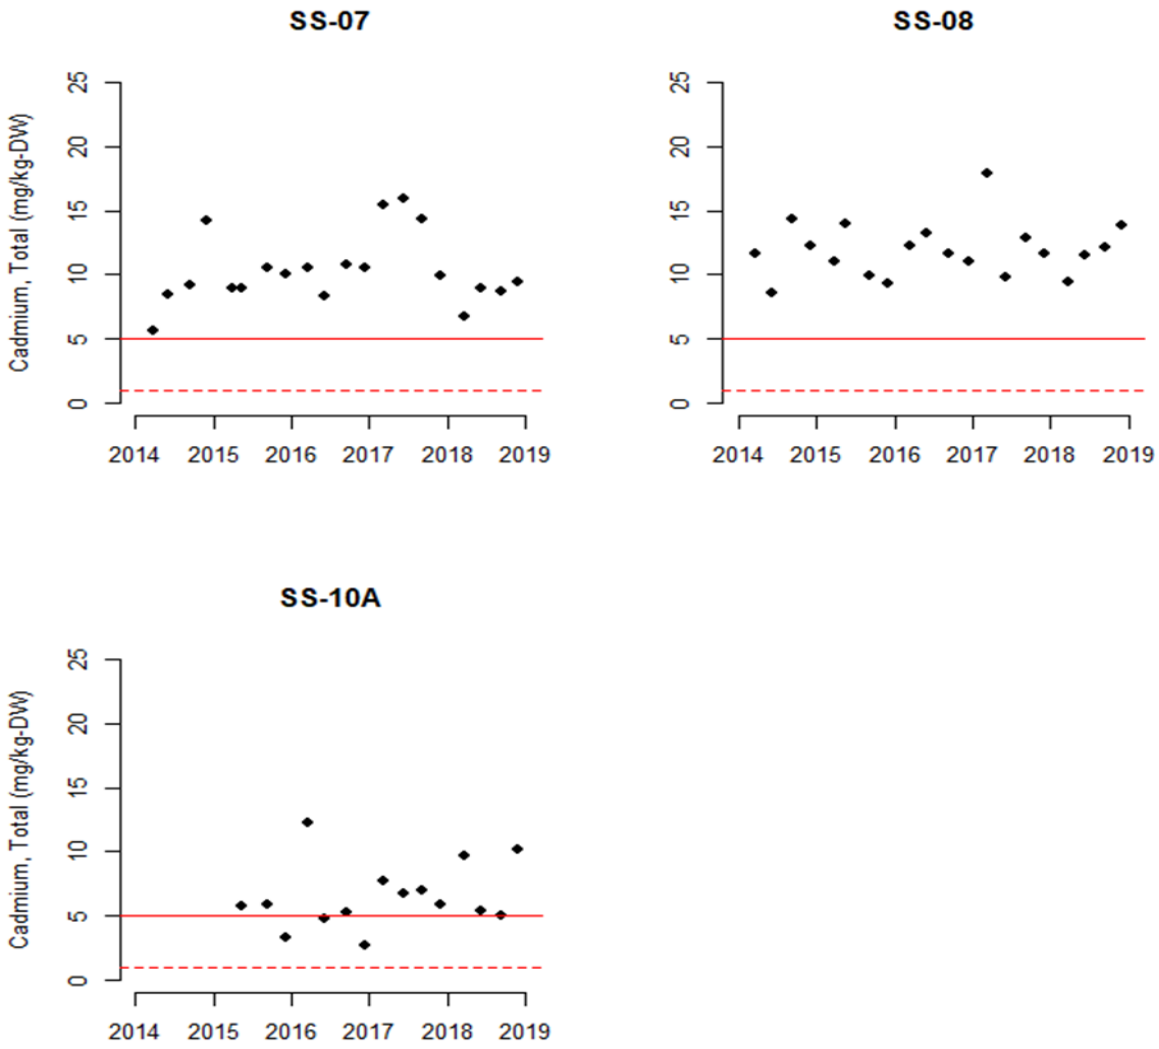

Figure 2-12. Fine fraction (<0.063 mm) total dry-weight cadmium concentrations (mg/kg-DW) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Solid red line is the 4.98 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.99 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

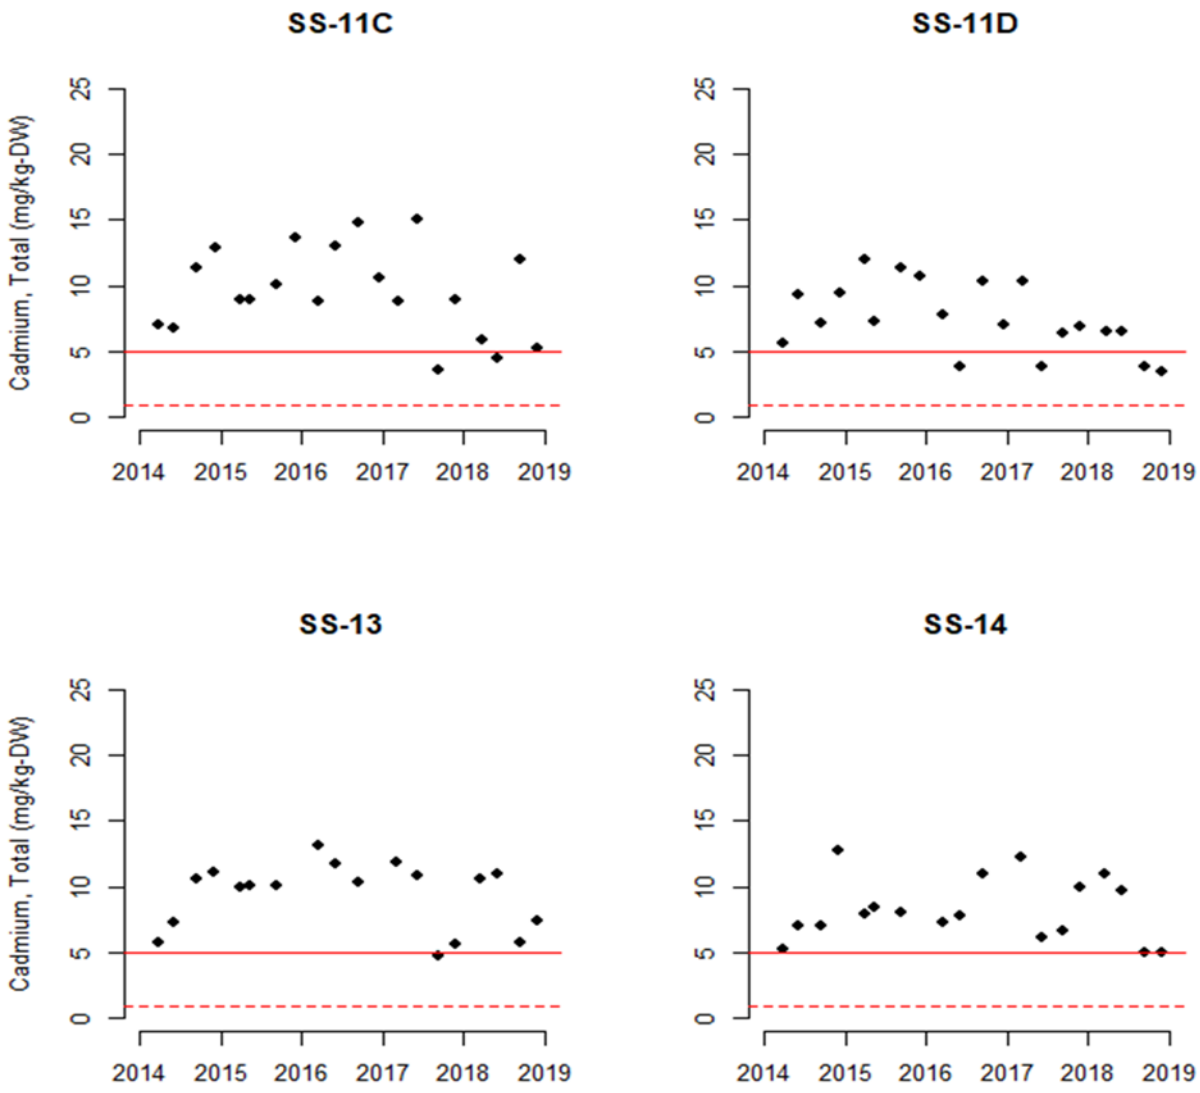

Figure 2-13. Fine fraction (<0.063 mm) total dry-weight cadmium concentrations (mg/kg-DW) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Solid red line is the 4.98 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.99 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

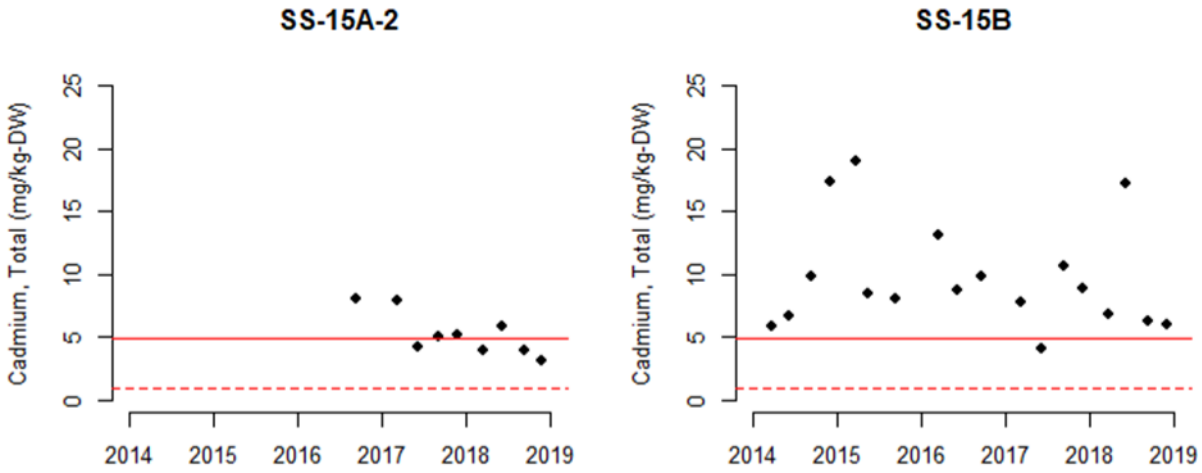

Figure 2-14. Fine fraction (<0.063 mm) total dry-weight cadmium concentrations (mg/kg-DW) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above German Gulch (Alternate Site, Site SS-15A-2), Silver Bow Creek above (Site SS-15A) and below (Site SS-15B) German Gulch. Solid red line is the 4.98 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.99 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

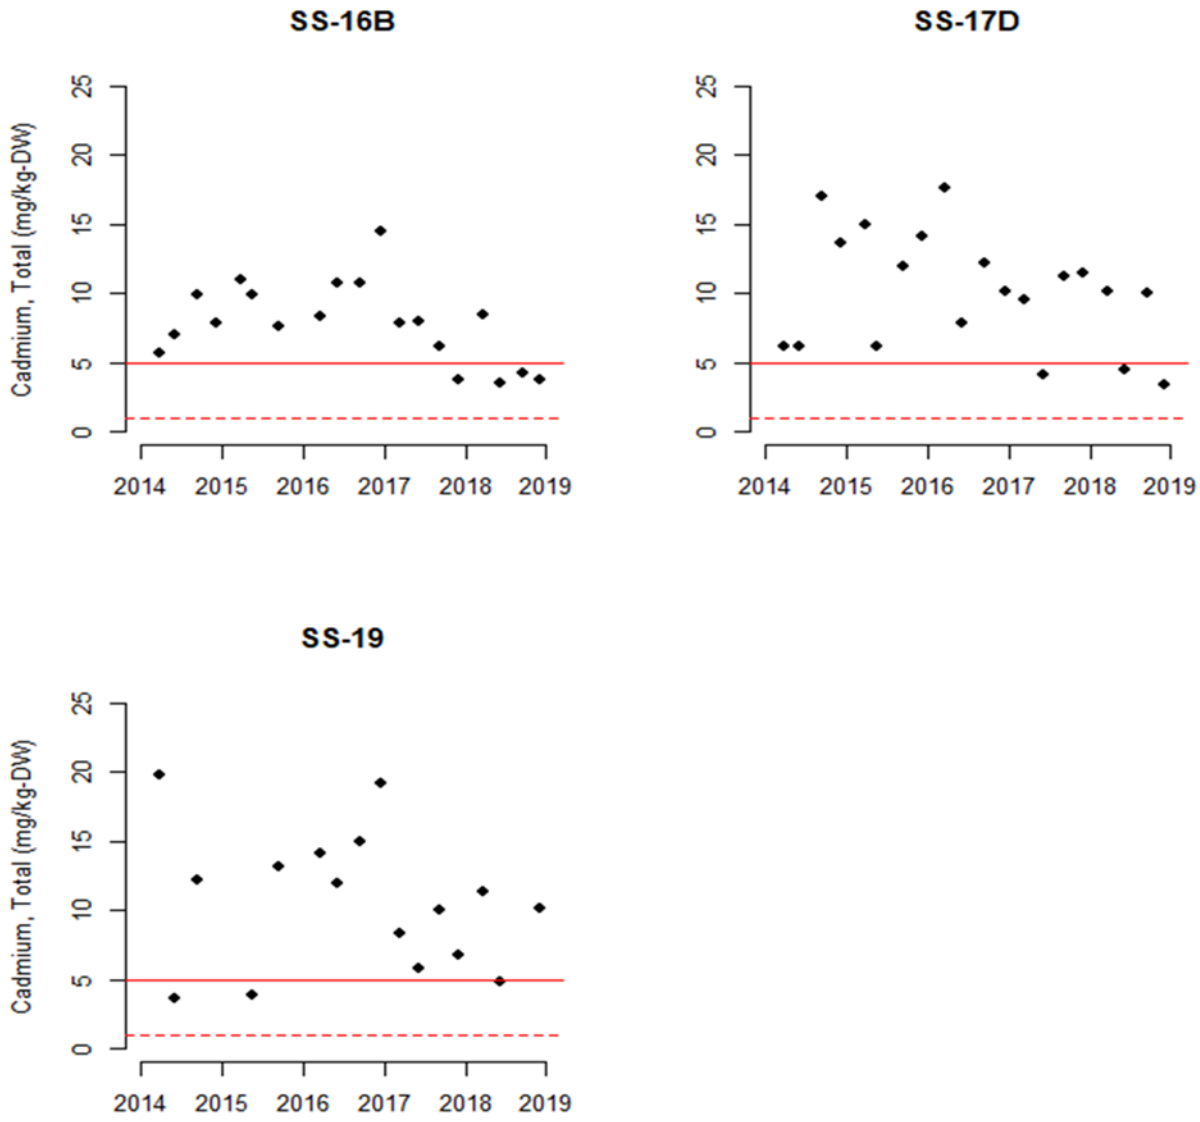

Figure 2-15. Fine fraction (<0.063 mm) total dry-weight cadmium concentrations (mg/kg-DW) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19) [38]. Solid red line is the 4.98 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.99 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

[38] One sample result at Site SS-19 is not depicted (97 mg/kg-DW on March 26, 2015).

2.4.2.3 Copper

Among all samples collected in 2018, sediment copper concentrations ranged from 78-6,970 mg/kg-DW in the <0.063 mm size fraction, from 14-993 mg/kg-DW in the 0.065-1 mm size fraction, and from 8-835 mg/kg-DW in the 1-2 mm size fraction (Table 2-10). Weighted mean concentrations ranged from 18-602 mg/kg-DW among samples with concentrations above the reporting limit in all three size fractions (Table 2-11). Based on the weighted mean concentrations, exceedances of the TEC occurred in 48 samples and the PEC was exceeded in 11 samples; weighted mean concentrations were not determined for samples from Sites SS-04 or SLAG-01 because only the fine fraction (<0.063 mm) concentrations were analyzed (Table 2-11).

Spatially, fine fraction (<0.063 mm) median copper concentrations increased between each site from Blacktail Creek at Father Sheehan Park (Site SS-01) downstream to Silver Bow Creek above the Butte Reduction Works (Site SS-05A), decreased sharply between Site SS-05A and downstream to Silver Bow Creek above Butte WWTP (Site SS-06G), then decreased gradually downstream to sites near Browns Gulch (Sites SS-11C and SS-11D), and then remained relatively constant downstream through the remainder of the SSTOU (Site SS-19) (Figure 2-16). Median concentrations in Silver Bow Creek below German Gulch (Site SS-15B) were slightly higher than adjacent sites (Figure 2-16) due to an elevated sample in Q2 (3,240 mg/kg)-DW (Table 2-10).

In "background" sites, fine fraction (<0.063 mm) median copper concentrations were approximately two times the PEC in Blacktail Creek at Father Sheehan Park (Site SS-01) and between the TEC and PEC in German Gulch (Site SS-15G) (Figure 2-16). Median concentrations in all SSTOU sites were well above both background sites (Figure 2-16).

Since 2014, copper concentrations were relatively constant through time at the background sites in Blacktail Creek (Site SS-01) and German Gulch (Site SS-15G) (Figure 2-17). In the Blacktail Creek background site (Site SS-01), the concentrations were generally slightly above the PEC whereas in the German Gulch background site (Site SS-15G) were generally slightly lower (Figure 2-17). None of the reference sites (Sites SS-04, SLAG-01, SS-05A, and SS-06G) demonstrated clear directional (i.e., monotonic) trends, although in 2018 concentrations at Site SS-04 were higher than prior years (Figure 2-17). In Subareas 1 and 2 no positive or negative trends were apparent (Figure 2-18; Figure 2-19). In Subarea 3, concentrations appear to be decreasing at each site but the Q2 2018 sample was quite elevated (Figure 2-19). In Subarea 4, concentrations at the Silver Bow Creek sites at Fairmont (Site SS-16B) and Opportunity (Site SS-17D) appear to be decreasing through time (Figure 2-21). No temporal trend is apparent at the Frontage Road site (Site SS-19), primarily due to the high degree of variability in the results (Figure 2-21).

Table 2-10. Total copper concentrations (mg/kg dry weight) by size fraction in quarterly instream sediment samples from Streamside Tailings Operable Unit monitoring stations, 2018.

DNA Does not apply because one or more sample fractions had ND concentration.

Exceeds the threshold effect concentration [MacDonald et al., 2000].

Exceeds the probable effect concentration [MacDonald et al., 2000].

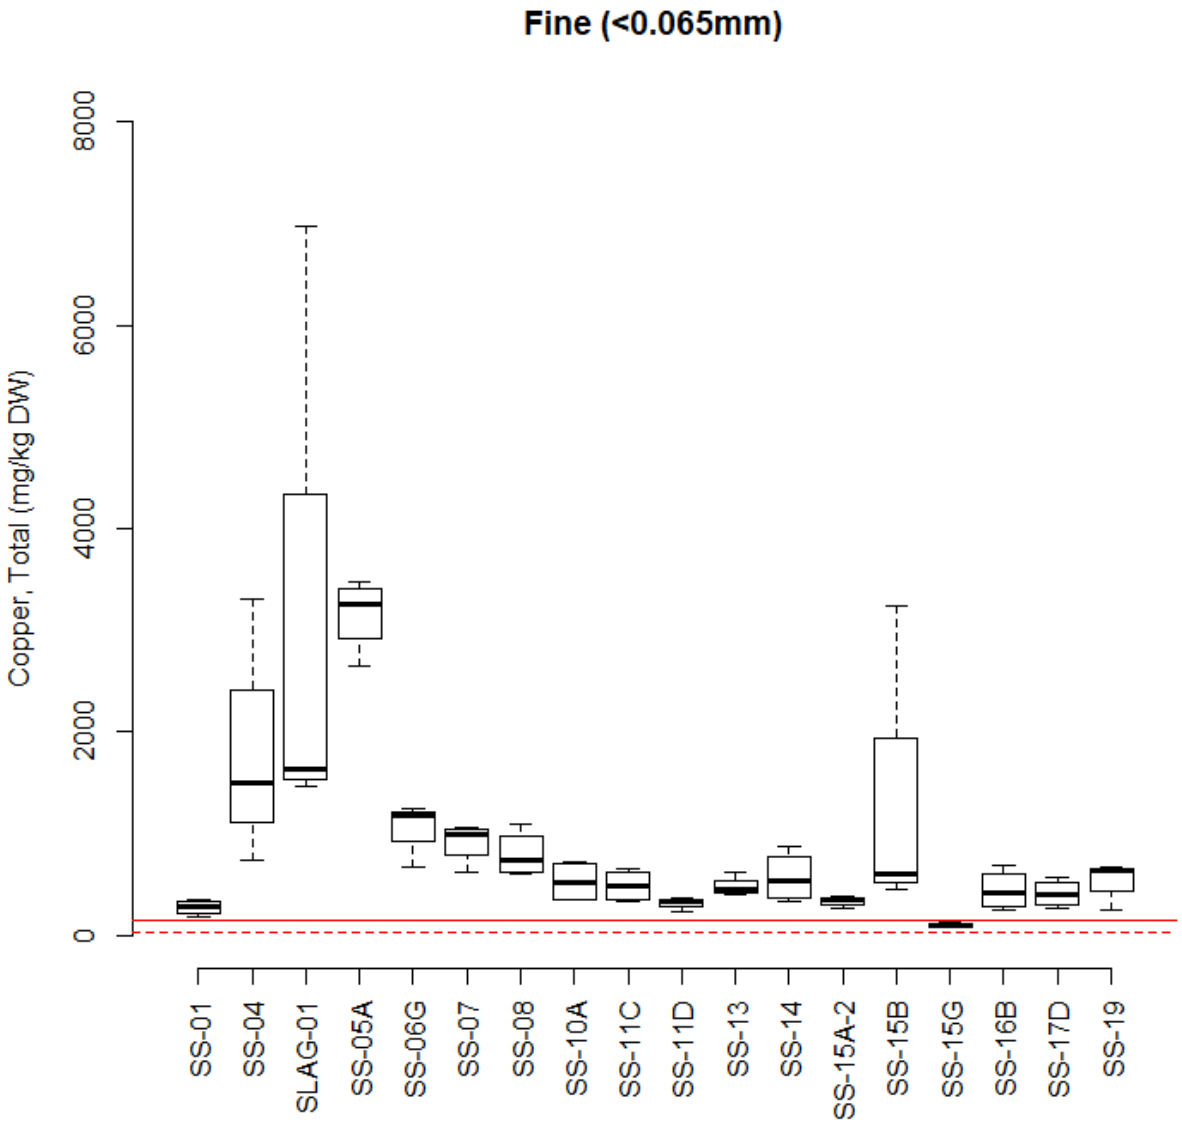

Figure 2-16. Total copper concentrations in instream sediment (<0.063 mm) samples collected at Streamside Tailings Operable Unit monitoring stations, 2018. Solid red line is the 149 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 31.6 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

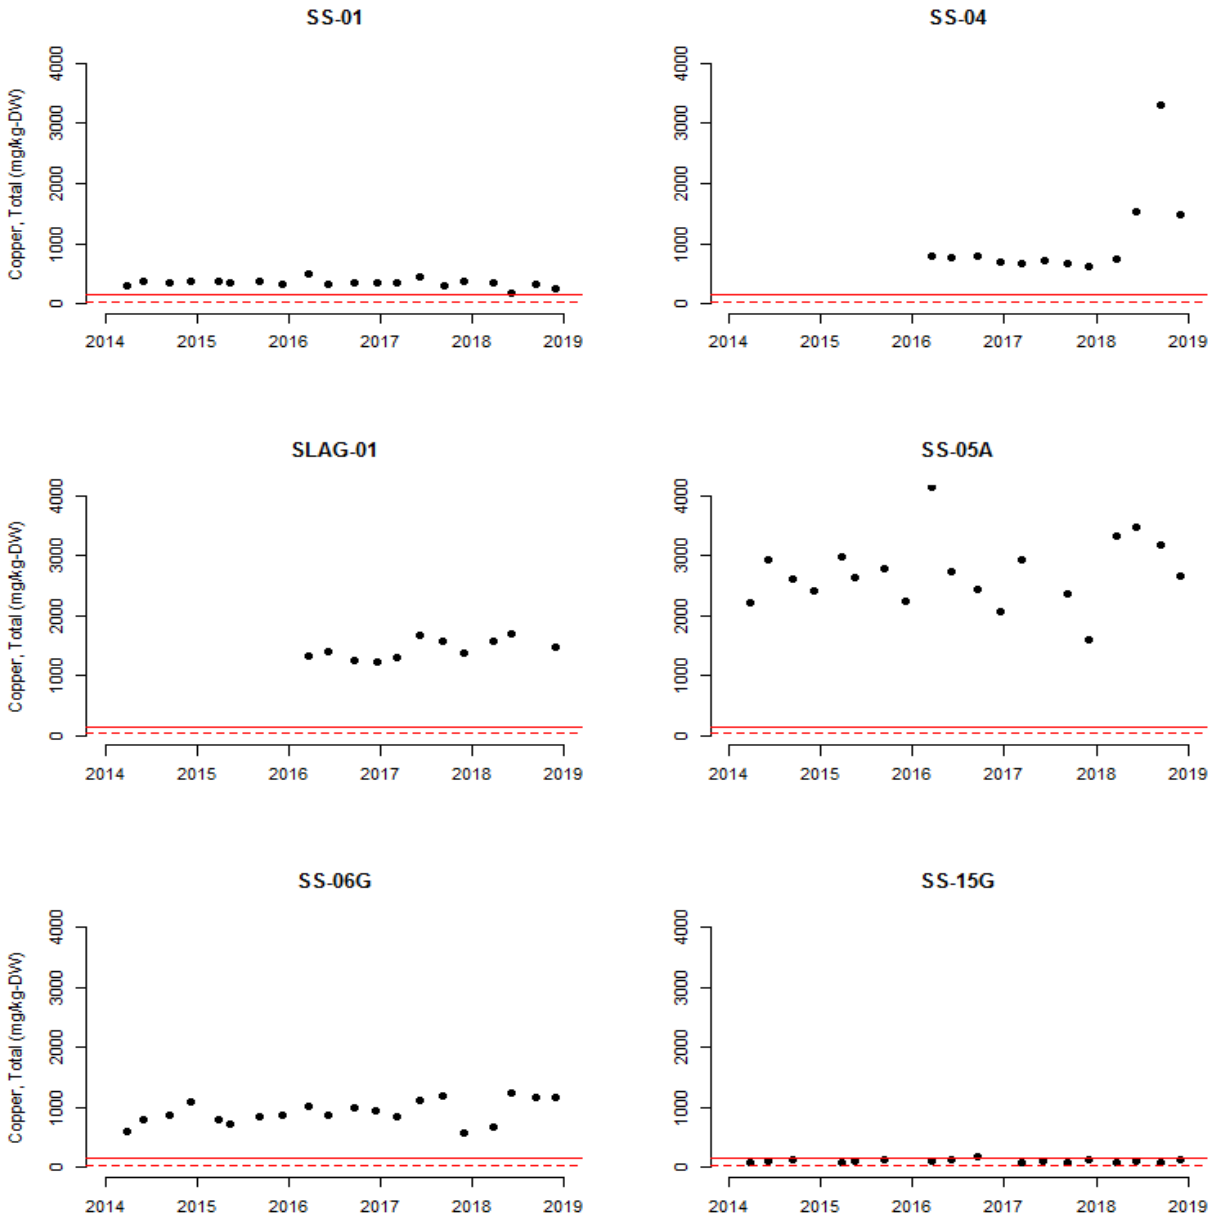

Figure 2-17. Fine fraction (<0.063 mm) total dry-weight copper concentrations (mg/kg-DW) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Blacktail Creek at Metro Storm Drain Confluence (Site SS-04), Silver Bow Creek in Slag Canyon (SLAG-01)[39], Silver Bow Creek above Butte Reduction Works (Site SS-05A)[40], Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Solid red line is the 149 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 31.6 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

[39] One outlier is not shown for Site SLAG-01 (6,970 mg/kg-DW on September 13, 2018).

[40] One outlier is not shown for Site SS-05A (5,610 mg/kg-DW on June 6, 2017).

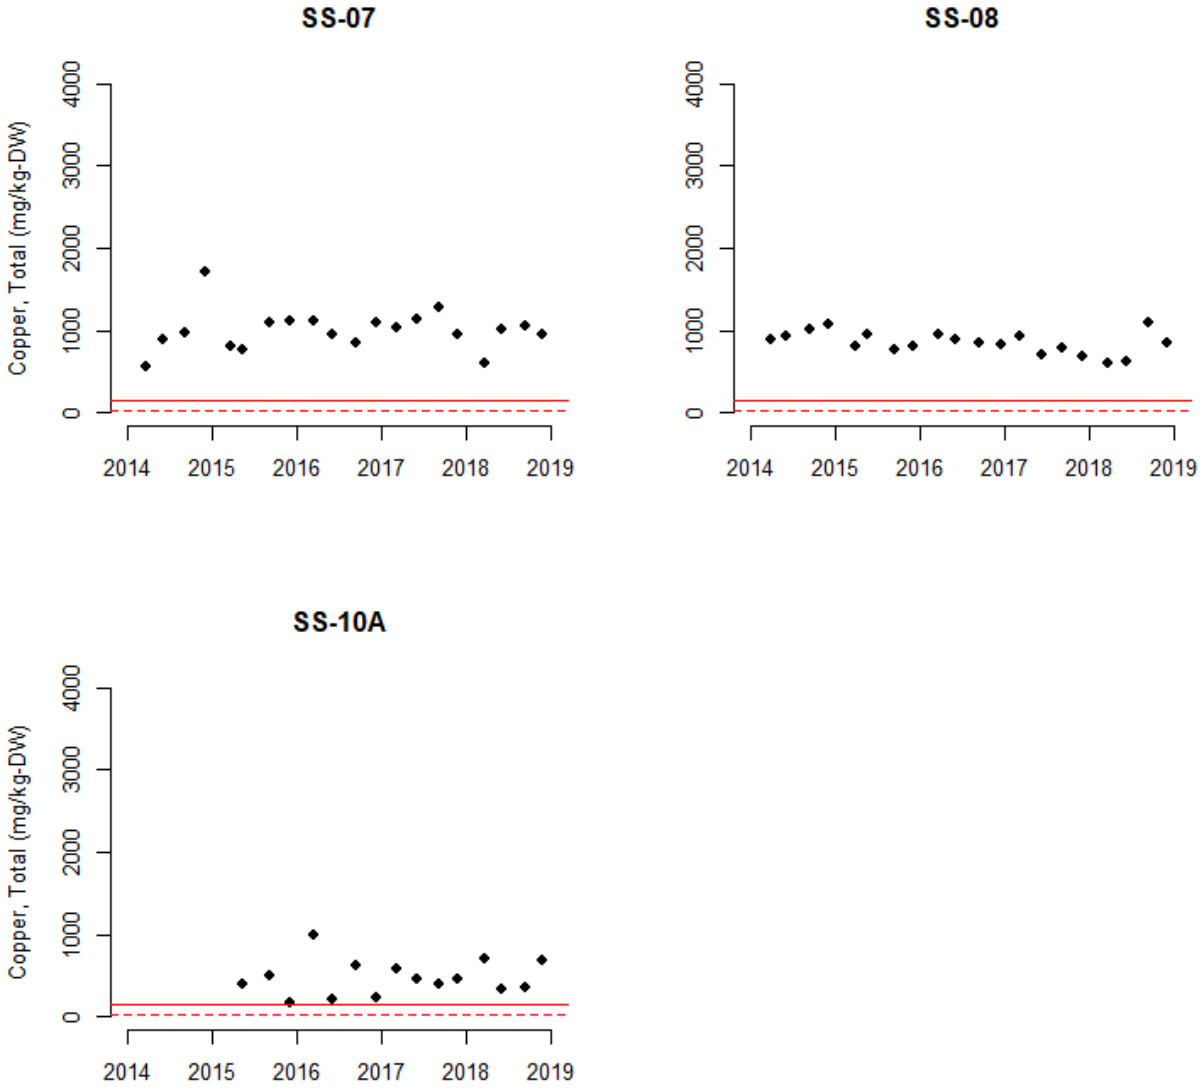

Figure 2-18. Fine fraction (<0.063 mm) total dry-weight copper concentrations (mg/kg-DW) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Solid red line is the 149 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 31.6 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

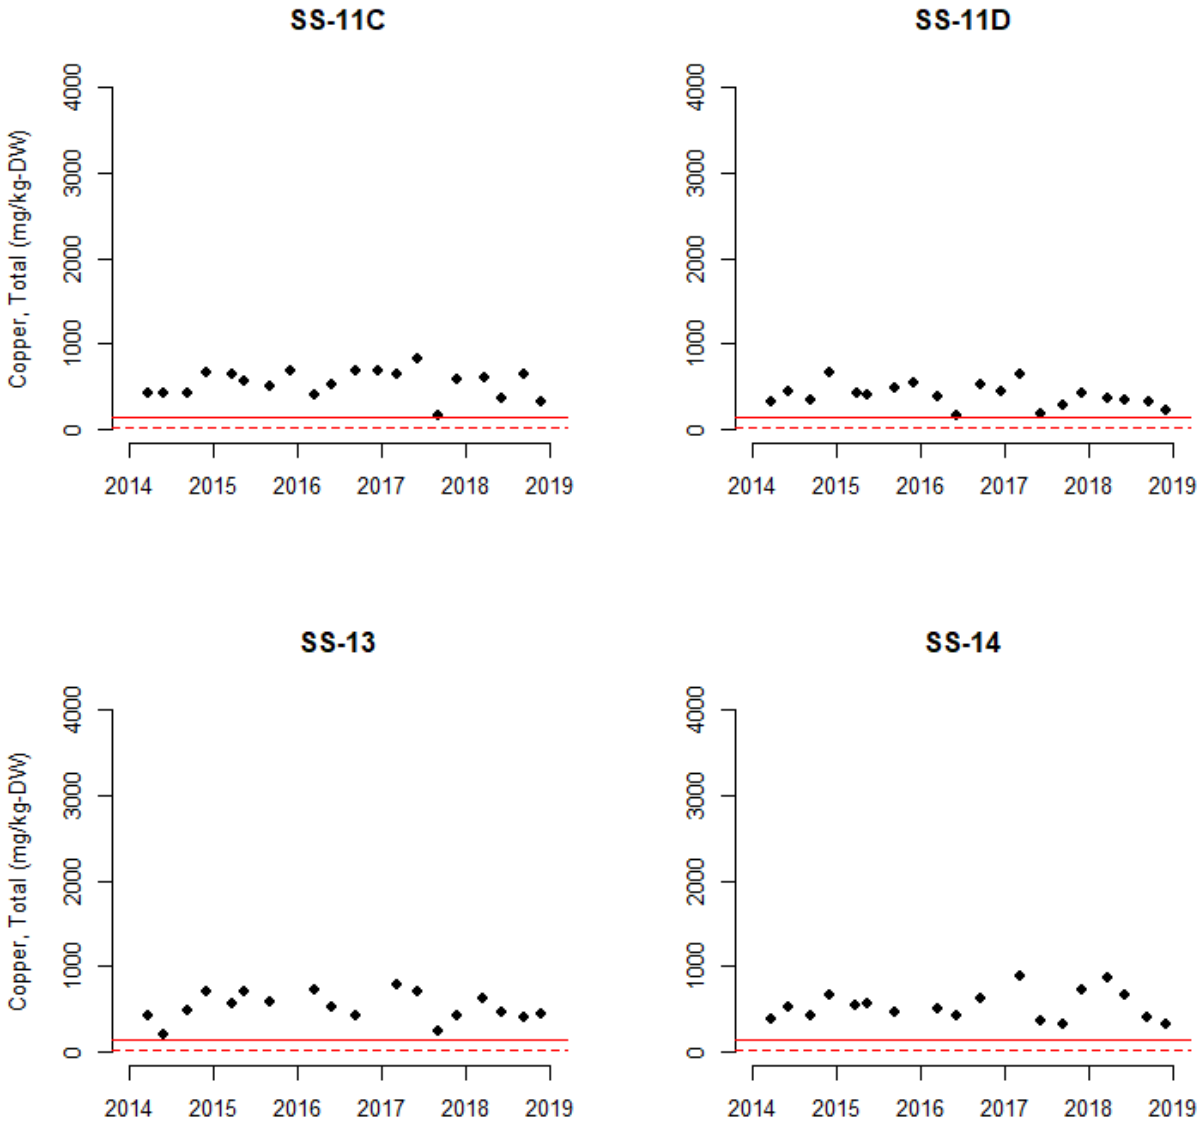

Figure 2-19. Fine fraction (<0.063 mm) total dry-weight copper concentrations (mg/kg-DW) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Solid red line is the 149 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 31.6 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

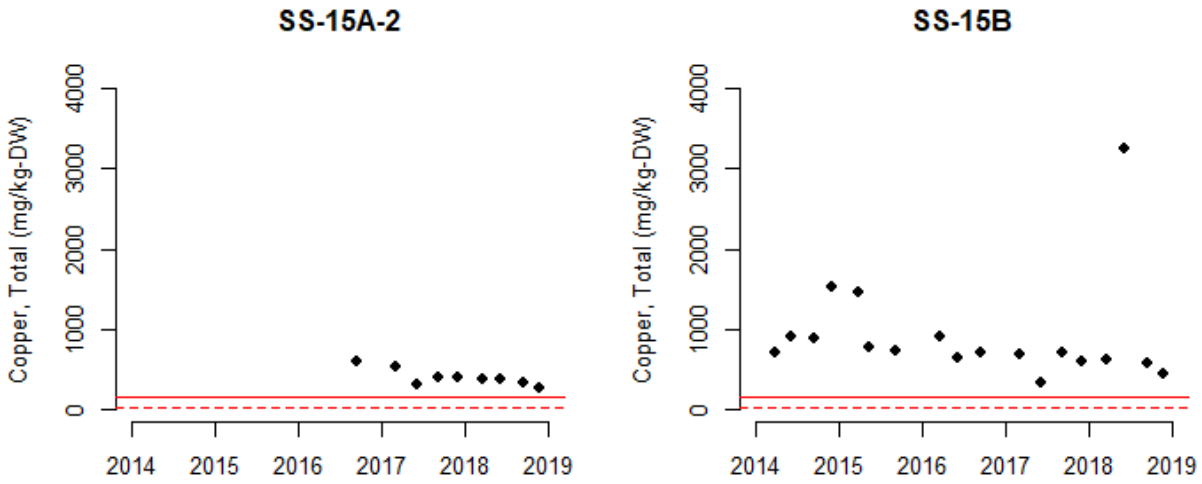

Figure 2-20. Fine fraction (<0.063 mm) total dry-weight copper concentrations (mg/kg-DW) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above German Gulch (Alternate Site, Site SS-15A-2), Silver Bow Creek above (Site SS-15A) and below (Site SS-15B) German Gulch. Solid red line is the 149 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 31.6 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

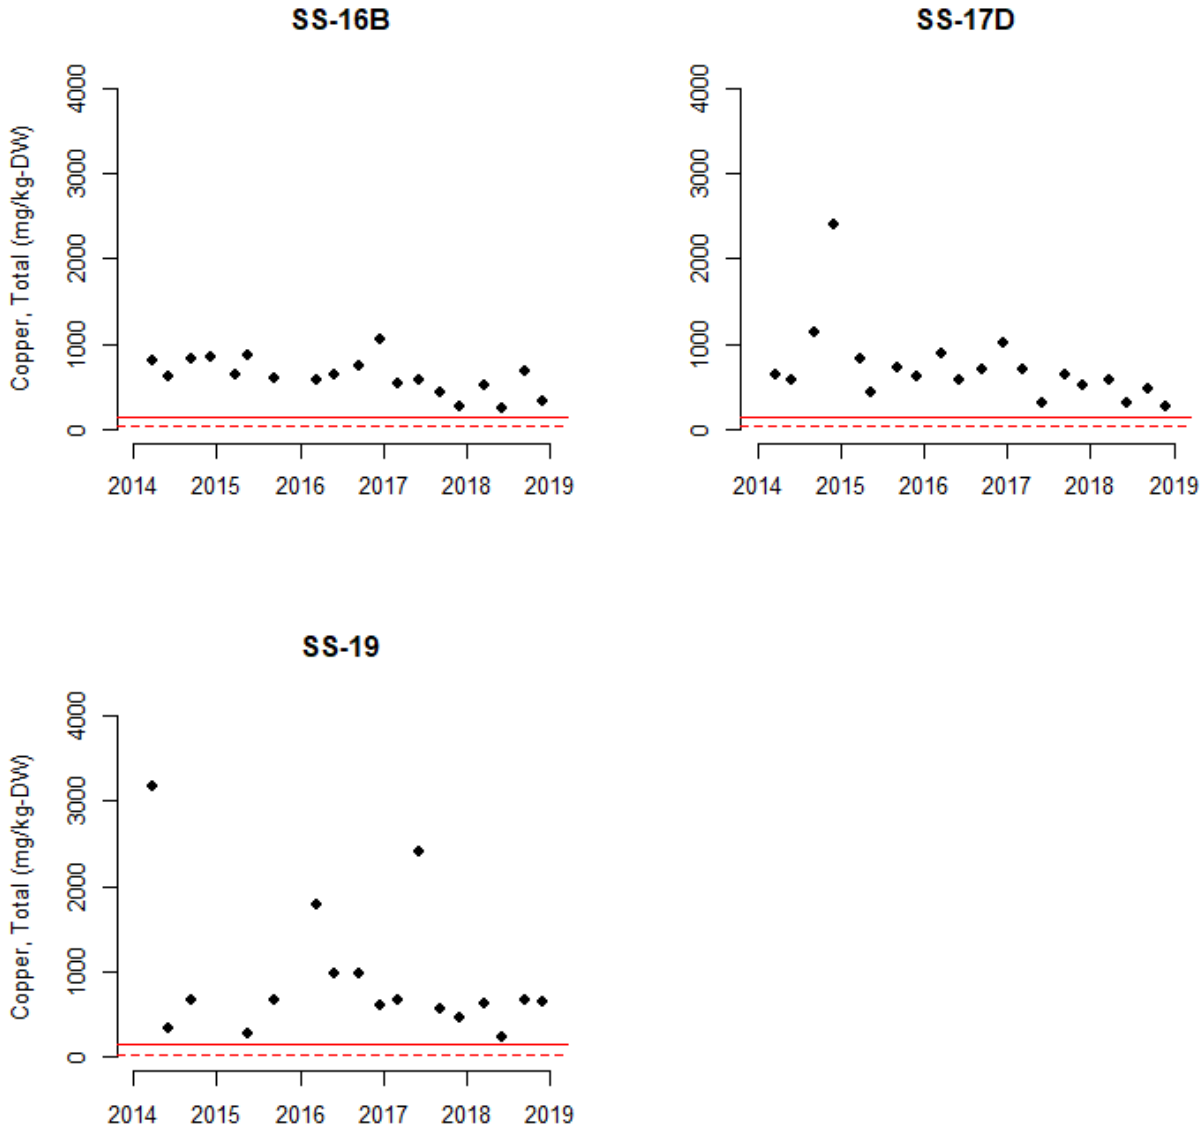

Figure 2-21. Fine fraction (<0.063 mm) total dry-weight copper concentrations (mg/kg-DW) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19) [41]. Solid red line is the 149 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 31.6 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

[41] One outlier is not depicted at Site SS-19 (35,700 mg/kg-DW on March 26, 2015).

2.4.2.4 Lead

Among all samples collected in 2018, sediment lead concentrations ranged from 54-1,230 mg/kg-DW in the <0.063 mm size fraction, from 5-882 mg/kg-DW in the 0.063-1 mm size fraction, and from 4.3-501 mg/kg-DW in the 1-2 mm size fraction (Table 2-12). Weighted mean concentrations ranged from 5.8-356 mg/kg-DW among samples with concentrations above the reporting limit in all three size fractions (Table 2-13). Based on the weighted mean concentrations, exceedances of the TEC occurred in 26 samples and the PEC was exceeded in 4 samples; weighted mean concentrations were not determined for eight samples because one or more size fractions were not sampled (Table 2-13).

Spatially, fine fraction (<0.063 mm) median lead concentrations increased between each site from Blacktail Creek at Father Sheehan Park (Site SS-01) downstream to Silver Bow Creek in Slag Canyon (Site SLAG-01), generally decreased downstream to Silver Bow Creek above Sand Creek (Site SS-10A), and then remained approximately level downstream to Silver Bow Creek at Opportunity (Site SS-17D) (Figure 2-22). In Subarea 3, the Silver Bow Creek below German Gulch site had an elevated median concentration (due to the Q2 sample; Table 2-12) relative to adjacent sites (Figure 2-22). In Subarea 4, Silver Bow Creek at Frontage Road (Site SS-19) also had an elevated median concentration (Figure 2-22).

In "background" sites, fine fraction (<0.063 mm) median lead concentrations were above the PEC in Blacktail Creek at Harrison Avenue (Site SS-01) and between the TEC and PEC in German Gulch (Site SS-15G) (Figure 2-22). In Subarea 1 and 2, median concentrations were well above background concentrations in Silver Bow Creek sites below the Butte WWTP (Site SS-07) and at Rocker (Site SS-08) but similar to background in all other Subarea 1 and 2 sites (Sites SS-10A, SS-11C, SS-11D, SS-13, and SS-14) (Figure 2-22). In Subarea 3, the median concentration at Site SS-15A-2 was similar to the background sites but below German Gulch (Site SS-15B) median concentrations were higher than background (Figure 2-22). Subarea 4 sites (Sites SS-16B, SS-17D, and SS-19) had median concentrations similar to background with the exception of Silver Bow Creek at Frontage Road which was higher than background (Figure 2-22).

Since 2014, lead concentrations were relatively constant and were generally at or slightly above the PEC at background sites in Blacktail Creek (Site SS-01) and German Gulch (Site SS-15G), with concentrations in Blacktail Creek consistently slightly higher than in German Gulch (Figure 2-23). None of the reference sites (Sites SS-04, SLAG-01, SS-05A, and SS-06G) demonstrated clear directional (i.e., monotonic) trends although some sites appear to demonstrate slight increasing trends (Figure 2-23). In Subareas 1, 2, and 3, no clear trends are apparent (Figure 2-24; Figure 2-25; Figure 2-26). In Subarea 4, concentrations at the Silver Bow Creek sites at Fairmont (Site SS-16B) and Opportunity (Site SS-17D) appear to be decreasing through time but no trend is apparent at the Frontage Road site (Site SS-19 (Figure 2-27).

DNA Does not apply because one or more sample fractions had ND concentration.

Exceeds the threshold effect concentration [MacDonald et al., 2000].

Exceeds the probable effect concentration [MacDonald et al., 2000].

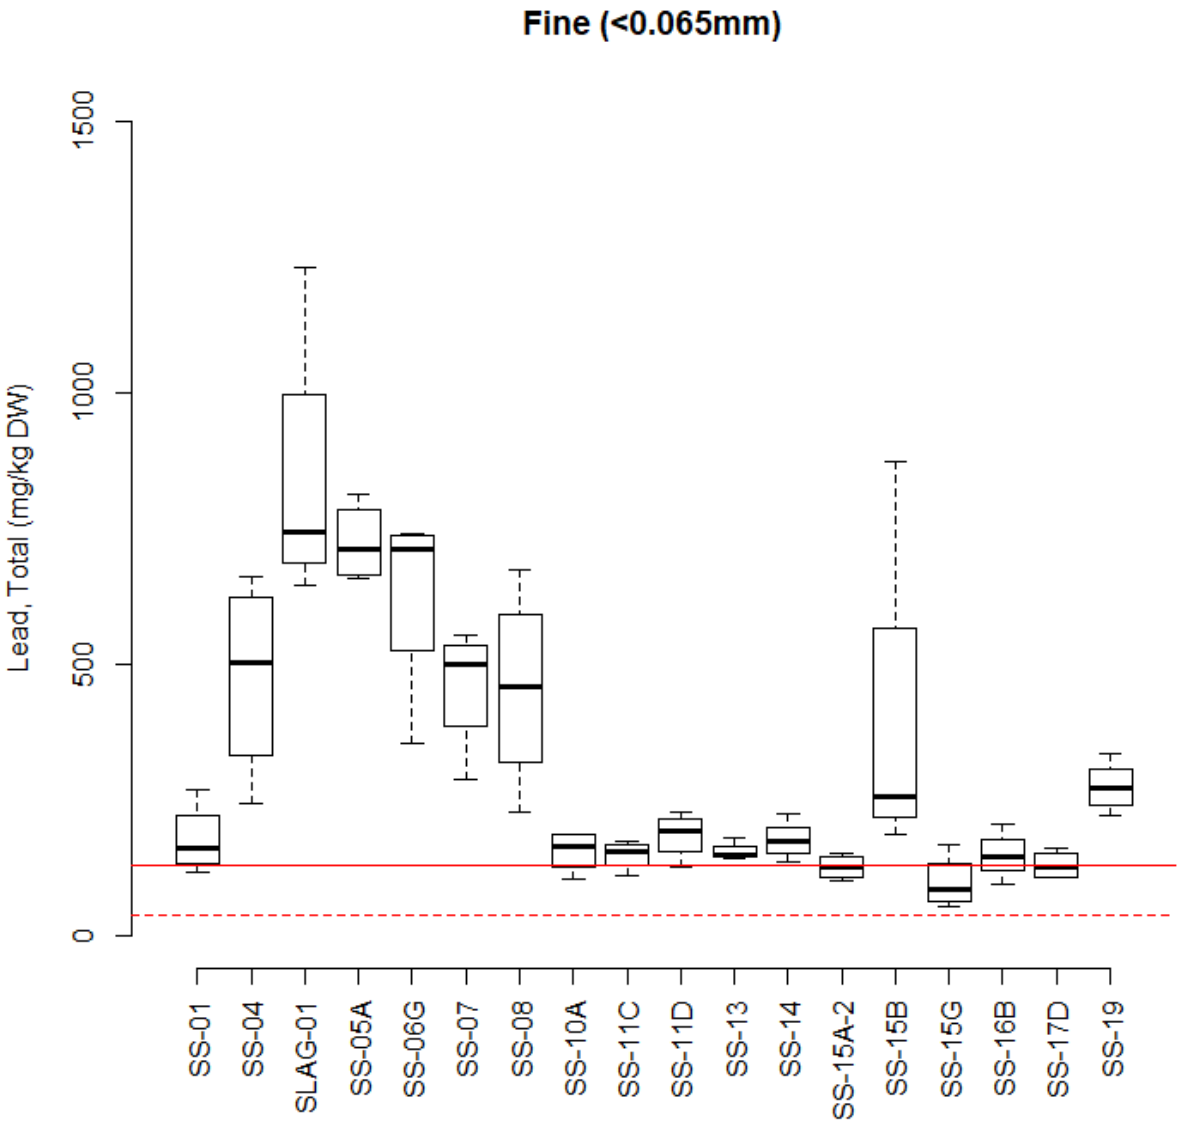

Figure 2-22. Total lead concentrations in instream sediment (<0.065 mm) samples collected at Streamside Tailings Operable Unit monitoring stations, 2018. Solid red line is the 128 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 35.8 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

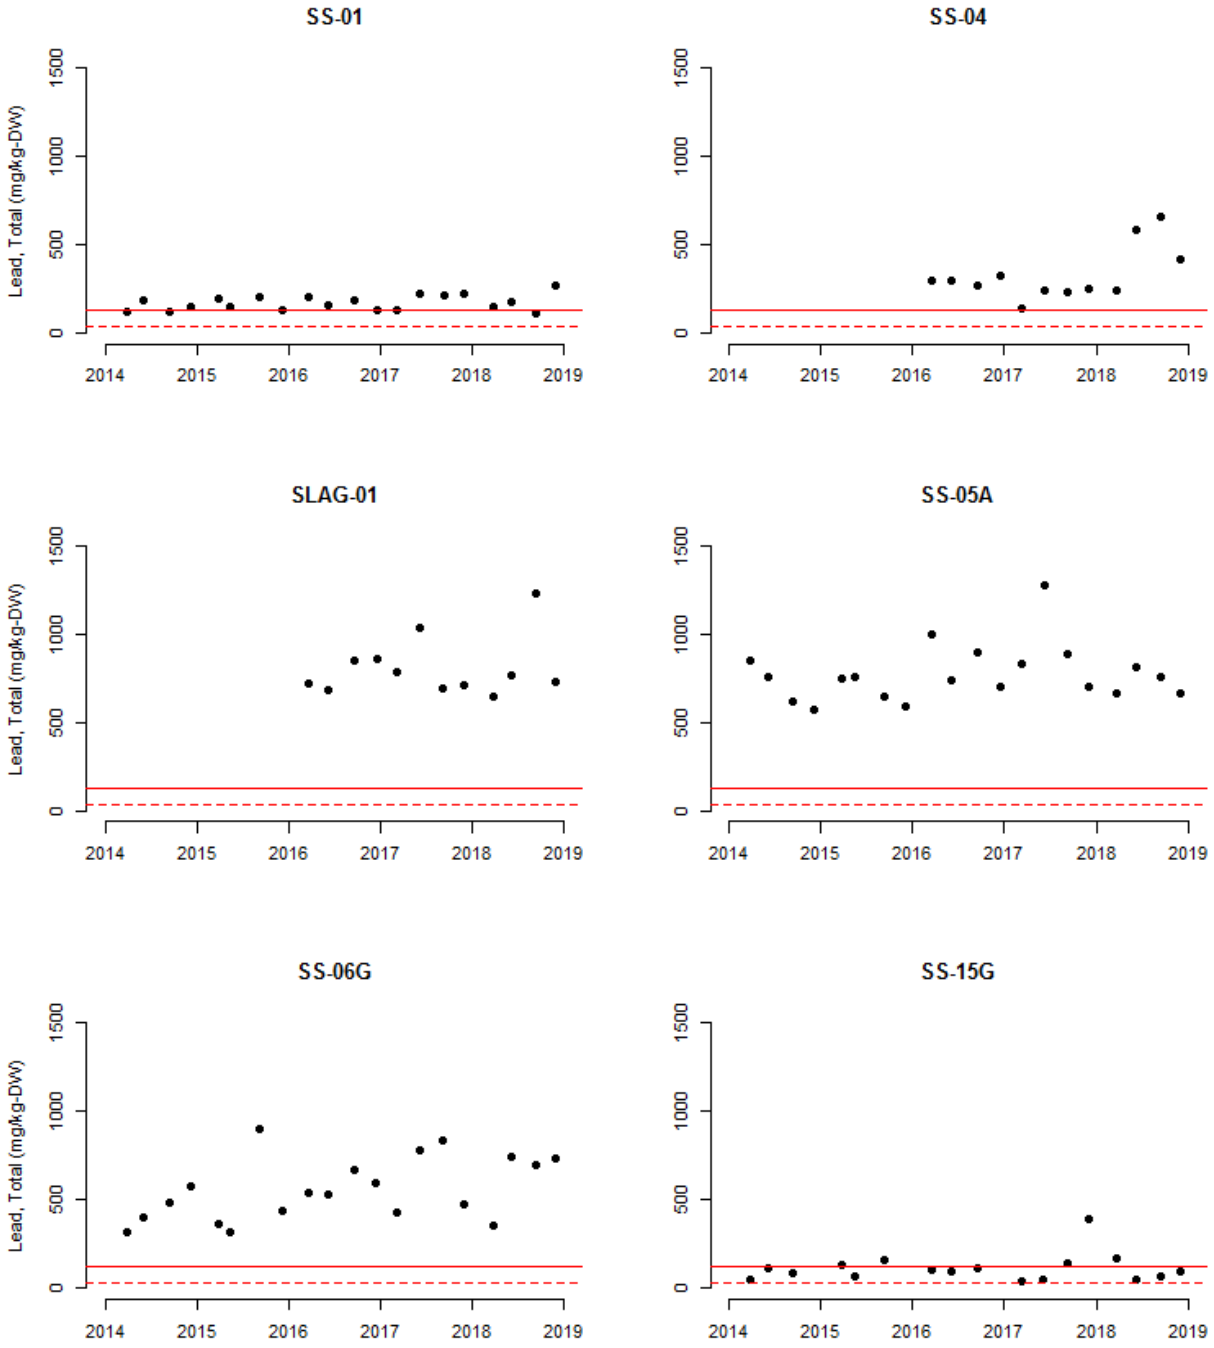

Figure 2-23. Fine fraction (<0.063 mm) total dry-weight lead concentrations (mg/kg-DW) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Blacktail Creek at Metro Storm Drain Confluence (Site SS-04), Silver Bow Creek in Slag Canyon (SLAG-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Solid red line is the 128 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 35.8 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

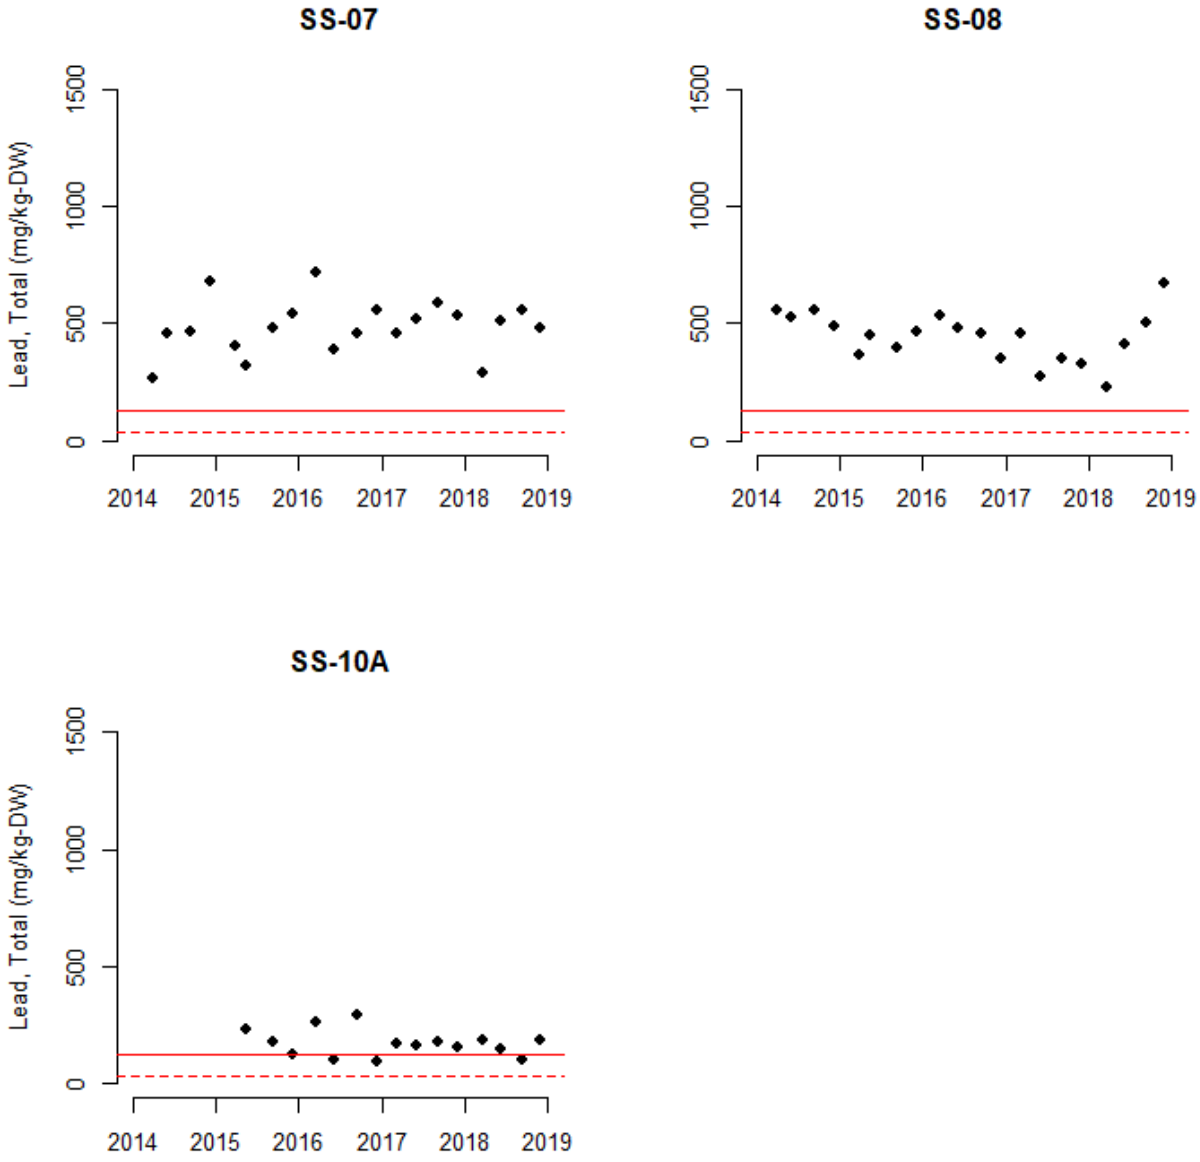

Figure 2-24. Fine fraction (<0.063 mm) total dry-weight lead concentrations (mg/kg-DW) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Solid red line is the 128 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 35.8 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

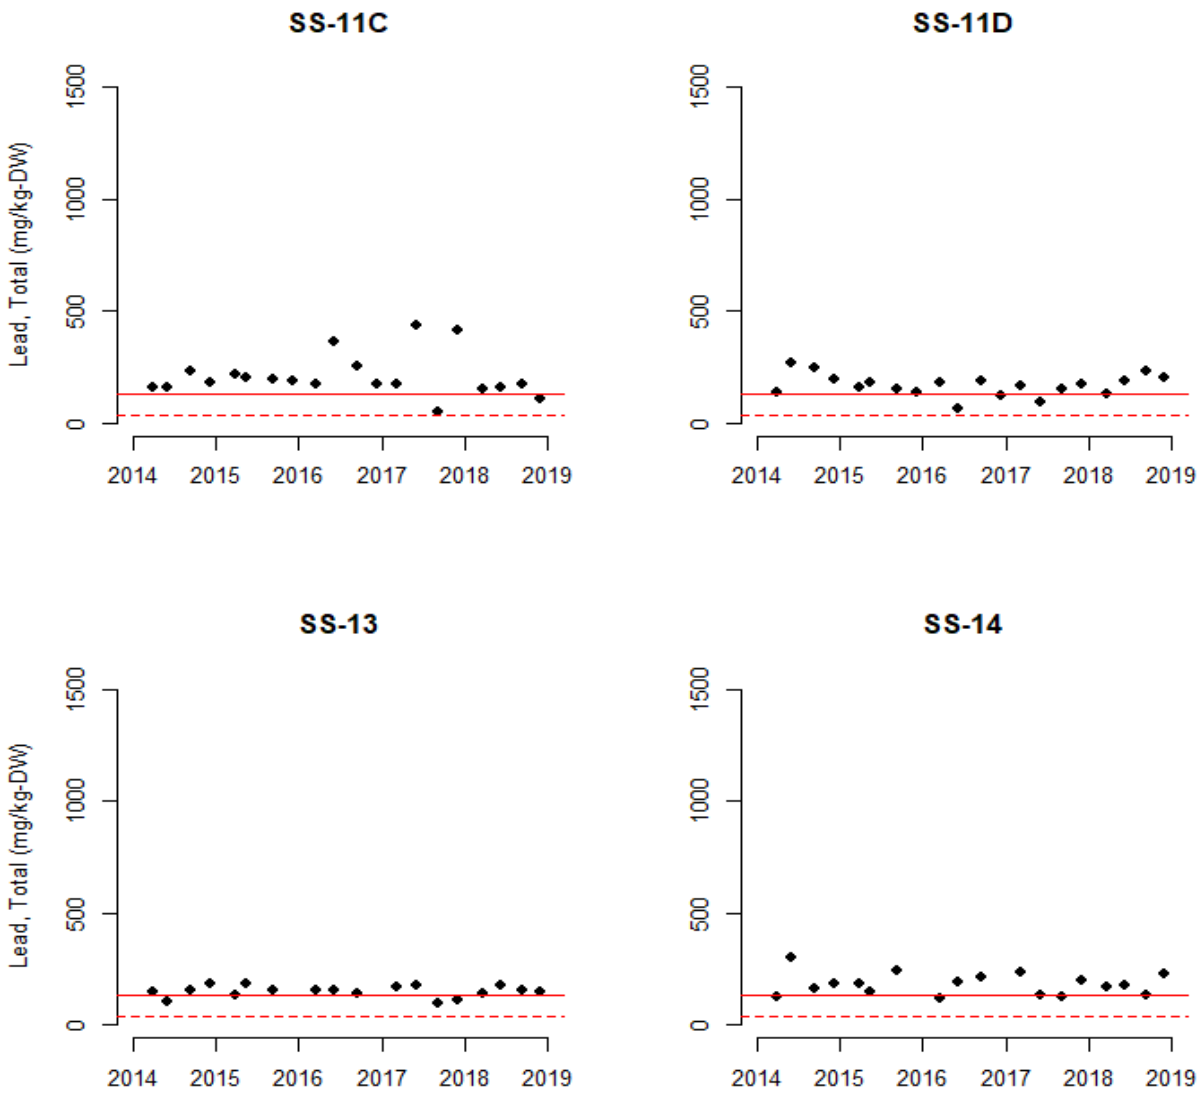

Figure 2-25. Fine fraction (<0.063 mm) total dry-weight lead concentrations (mg/kg-DW) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Solid red line is the 128 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 35.8 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

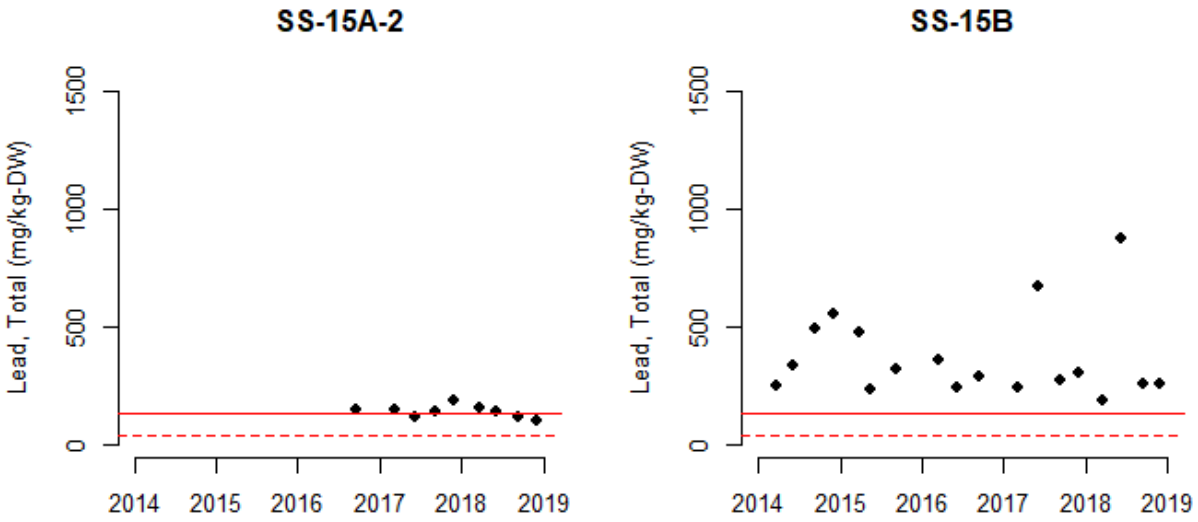

Figure 2-26. Fine fraction (<0.063 mm) total dry-weight lead concentrations (mg/kg-DW) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above German Gulch (Alternate Site, Site SS-15A-2), Silver Bow Creek above (Site SS-15A) and below (Site SS-15B) German Gulch. Solid red line is the 128 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 35.8 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

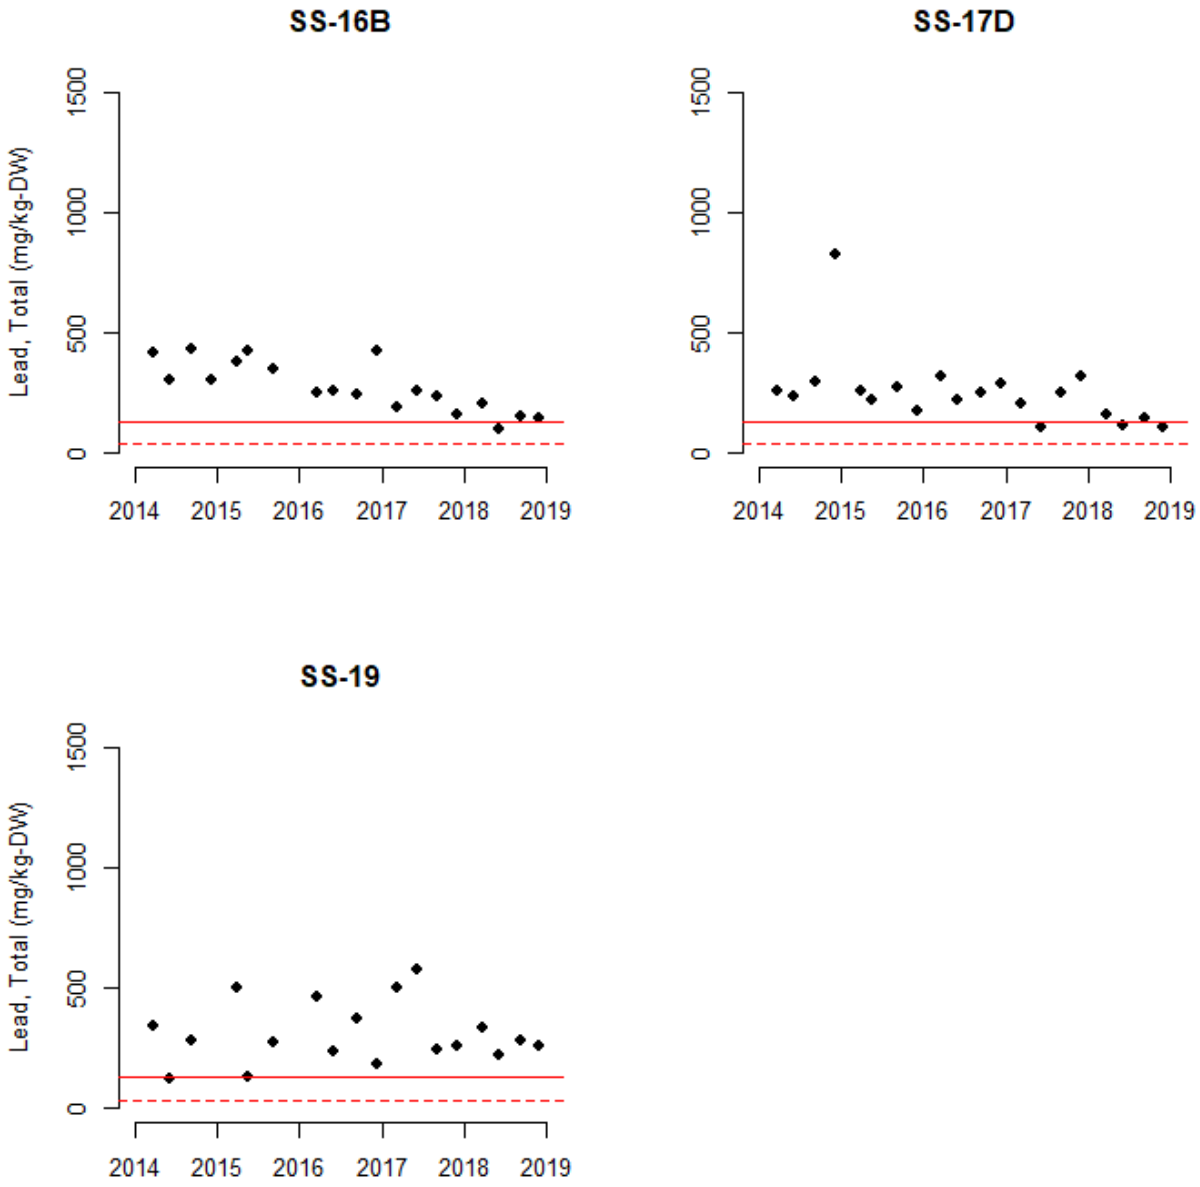

Figure 2-27. Fine fraction (<0.063 mm) total dry-weight lead concentrations (mg/kg-DW) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Solid red line is the 128 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 35.8 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

2.4.2.5 Mercury

Among all samples collected in 2018, sediment mercury concentrations ranged from 0.14-6.3 mg/kg-DW in the <0.063 mm size fraction, from <0.0018-0.43 mg/kg-DW in the 0.065-1 mm size fraction, and from <0.0018-0.93 mg/kg-DW in the 1-2 mm size fraction (Table 2-14). Weighted mean concentrations ranged from 0.01-0.98 mg/kg-DW among samples with concentrations above the reporting limit in all three size fractions (Table 2-15). Based on the weighted mean concentrations, exceedances of the TEC occurred in 10 samples and the PEC was exceeded in 0 samples; weighted mean concentrations were not determined for 21 samples because one or more size fractions for that sample had a concentration below the analytical reporting limit and therefore weighted mean concentrations could not be determined (Table 2-15).

Fine fraction (<0.063 mm) median mercury concentrations were similar among sites with some local deviations (Figure 2-28). Median concentrations were generally higher in Butte and upper Subarea 1 sites (Sites SS-05A, SS-06G, SS-07, and SS-08), particularly at Site SS-08, relative to other sites (Figure 2-28). Median concentrations in Silver Bow Creek below German Gulch (Site SS-15B) were similar to other sites (Figure 2-28) but the concentration at this site in Q2 was substantially higher (6.2 mg/kg-DW) than any other sample from the SSTOU in 2018 (Table 2-14). Sharp increases in median concentrations occurred between Blacktail Creek at Harrison Avenue (Site SS-01) and Silver Bow Creek at the Butte Reduction works (Site SS-05A) and between Silver Bow Creek below Butte WWTP (Site SS-07) and at Rocker (Site SS-08) (Figure 2-28).

In "background" sites (i.e., Sites SS-01 and SS-15G), fine fraction (<0.063 mm) median mercury concentrations were similar and were slightly above the TEC (Figure 2-28). Median concentrations in all SSTOU sites were above background and but only the median concentration at Rocker (Site SS-08) exceeded the PEC (Figure 2-28).

Since 2014, mercury concentrations were relatively constant and were generally at or slightly below the PEC at the Blacktail Creek background site (Site SS-01) and at or slightly below the TEC in the German Gulch background site (Site SS-15G) (Figure 2-29). None of the reference sites (Sites SS-04, SLAG-01, SS-05A, and SS-06G) demonstrated clear directional (i.e., monotonic) trends (Figure 2-29). In Subarea 1 and 2, no clear trends are apparent (Figure 2-30; Figure 2-31). Both Subarea 3 sites appear to have decreasing concentrations through time (Figure 2-32). In Subarea 4, concentrations at Silver Bow Creek at Fairmont (Site SS-16B) appear to be decreasing through time but no other sites demonstrated increasing or decreasing trends (Figure 2-33).

Table 2-14. Total mercury concentrations (mg/kg dry weight) by size fraction in quarterly instream sediment samples from Streamside Tailings Operable Unit monitoring stations, 2018.

---	Not sampled in all three size fractions.
DNA	Does not apply because one or more sample fractions had ND concentration.
	Exceeds the threshold effect concentration [MacDonald et al., 2000].
	Exceeds the probable effect concentration [MacDonald et al., 2000].

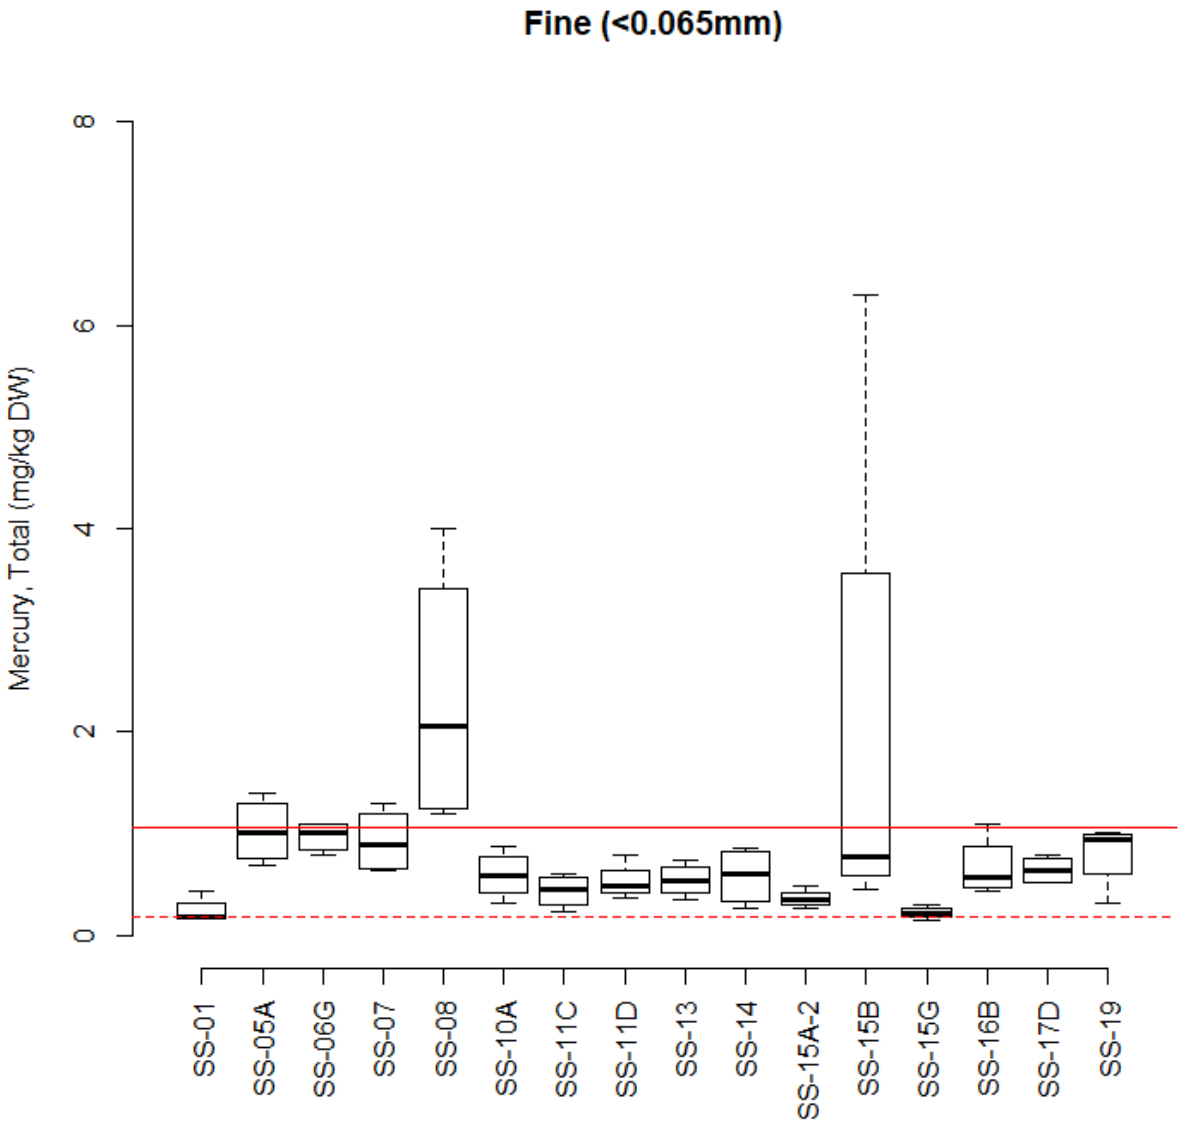

Figure 2-28. Total mercury concentrations in instream sediment (<0.063 mm) samples collected at Streamside Tailings Operable Unit monitoring stations, 2018. The upper whisker of Site SS-15A extends to 17 mg/kg. Solid red line is the 1.06 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.18 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

Figure 2-29. Fine fraction (<0.063 mm) total dry-weight mercury concentrations (mg/kg-DW) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Blacktail Creek at Metro Storm Drain Confluence (Site SS-04), and Silver Bow Creek in Slag Canyon (SLAG-01) were not analyzed for mercury. Solid red line is the 1.06 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.18 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

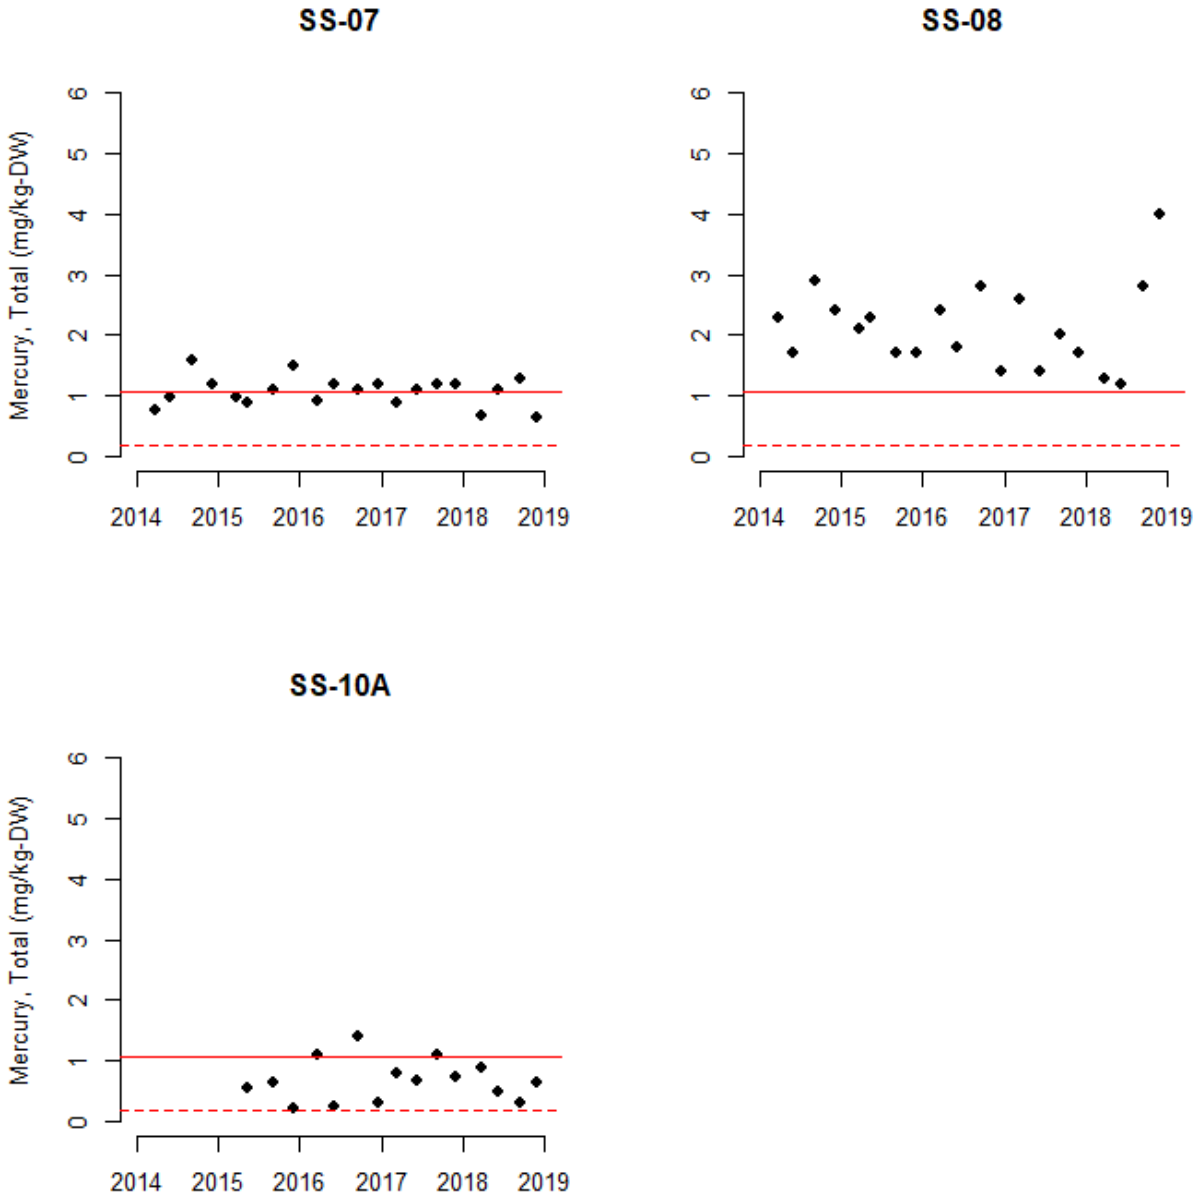

Figure 2-30. Fine fraction (<0.063 mm) total dry-weight mercury concentrations (mg/kg-DW) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Solid red line is the 1.06 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.18 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

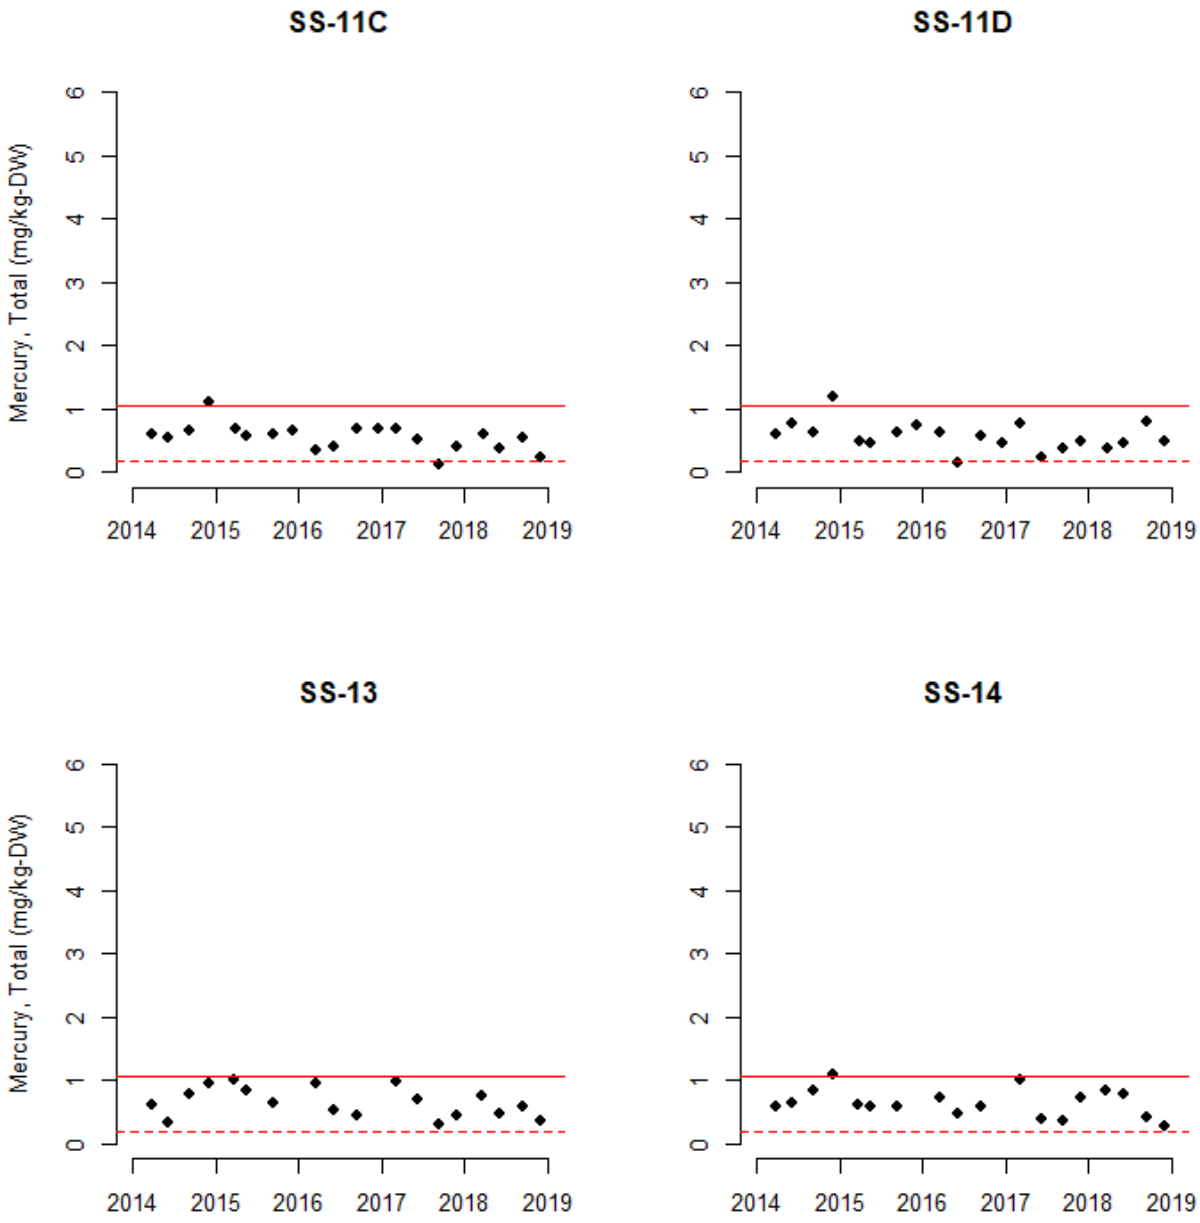

Figure 2-31. Fine fraction (<0.063 mm) total dry-weight mercury concentrations (mg/kg-DW) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Solid red line is the 1.06 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.18 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

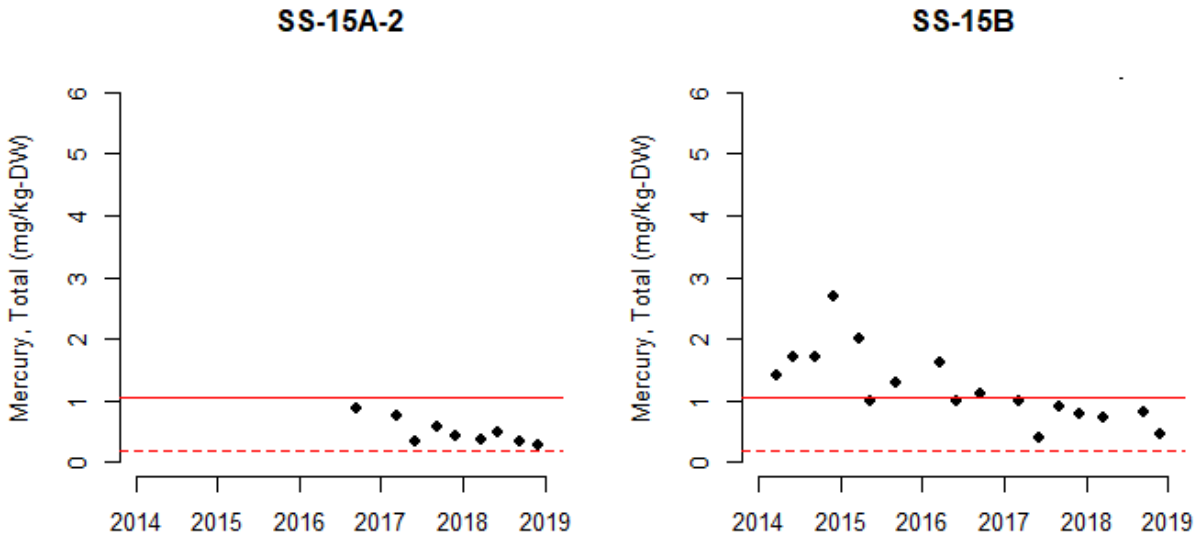

Figure 2-32. Fine fraction (<0.063 mm) total dry-weight mercury concentrations (mg/kg-DW) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above German Gulch (Alternate Site, Site SS-15A-2), Silver Bow Creek above (Site SS-15A) and below (Site SS-15B) Solid red line is the 1.06 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.18 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

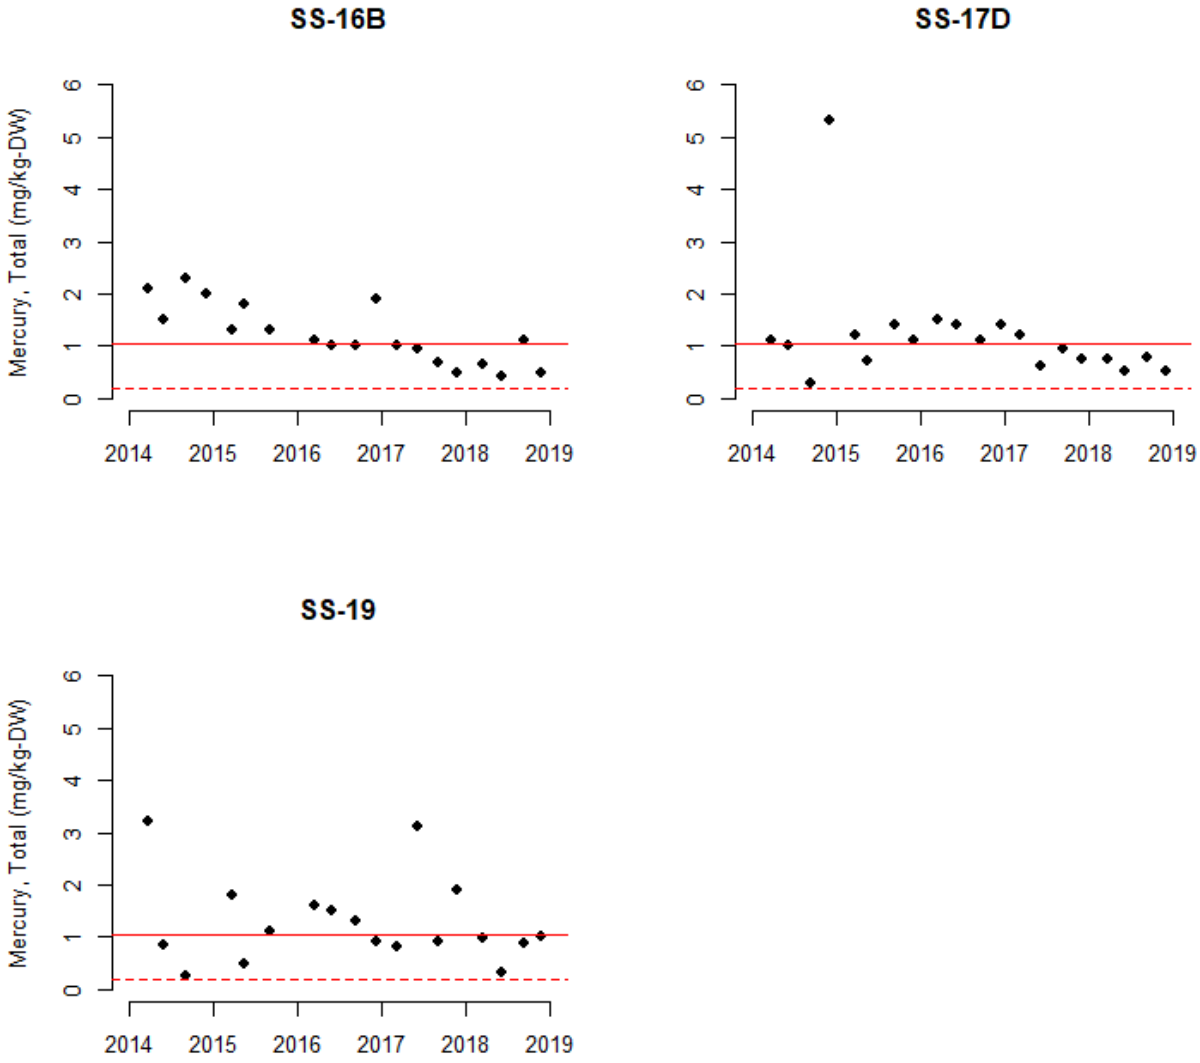

Figure 2-33. Fine fraction (<0.063 mm) total dry-weight mercury concentrations (mg/kg-DW) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19). Solid red line is the 1.06 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 0.18 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

2.4.2.6 Zinc

Among all samples collected in 2018, sediment zinc concentrations ranged from 110-4,660 mg/kg-DW in the <0.063 mm size fraction, from 35-1,720 mg/kg-DW in the 0.065-1 mm size fraction, and from 24-1,730 mg/kg-DW in the 1-2 mm size fraction (Table 2-16). Weighted mean concentrations ranged from 40-1,156 mg/kg-DW among samples with concentrations above the reporting limit in all three size fractions (Table 2-17). Based on the weighted mean concentrations, exceedances of the TEC occurred in 44 samples and the PEC was exceeded in 10 samples; weighted mean concentrations were not determined for the eight samples collected from Sites SS-04 and SLAG-01 because only the fine fraction concentrations were analyzed for those samples (Table 2-17).

Spatially, fine fraction (<0.063 mm) median zinc concentrations increased sharply from the Blacktail Creek site at Harrison Avenue (Site SS-01) to the site above the Metro Storm Drain (Site SS-04), then increased incrementally at each site downstream to Silver Bow Creek above Butte Reduction Works (Site SS-05A), then decreased steadily downstream to the Silver Bow Creek sites near Browns Gulch (Sites SS-11C and SS-11D) (Figure 2-34). Downstream from the Browns Gulch sites, median concentrations increased somewhat and were generally more variable (Figure 2-34).

In "background" sites (i.e., Sites SS-01 and SS-15G), fine fraction (<0.063 mm) median zinc concentrations were similar and were between the TEC and PEC (Figure 2-34). Median concentrations in all SSTOU sites were well above background and were generally above the PEC (Figure 2-34).

Since 2014, zinc concentrations were relatively constant and were generally at or slightly above the PEC at background sites in Blacktail Creek (Site SS-01) and German Gulch (Site SS-15G) (Figure 2-35). None of the reference sites (Sites SS-04, SLAG-01, SS-05A, and SS-06G) demonstrated clear directional (i.e., monotonic) trends although some sites appear to demonstrate slight increasing trends (Figure 2-35). In Subareas 1, 2, and 3, there were no clear increasing or decreasing trends with the possible exception of Siler Bow Creek above German Gulch which may be decreasing (Site SS-15A-2) (Figure 2-36; Figure 2-37; Figure 2-38). In Subarea 4, all sites appear to have decreasing trends, although that trend is less clear at the Frontage Road site (Site SS-19), primarily due to the high degree of variability in the results (Figure 2-39).

Table 2-16. Total zinc concentrations (mg/kg dry weight) by size fraction in quarterly instream sediment samples from Streamside Tailings Operable Unit monitoring stations, 2018.

Exceeds the threshold effect concentration [MacDonald et al., 2000].

Exceeds the probable effect concentration [MacDonald et al., 2000].

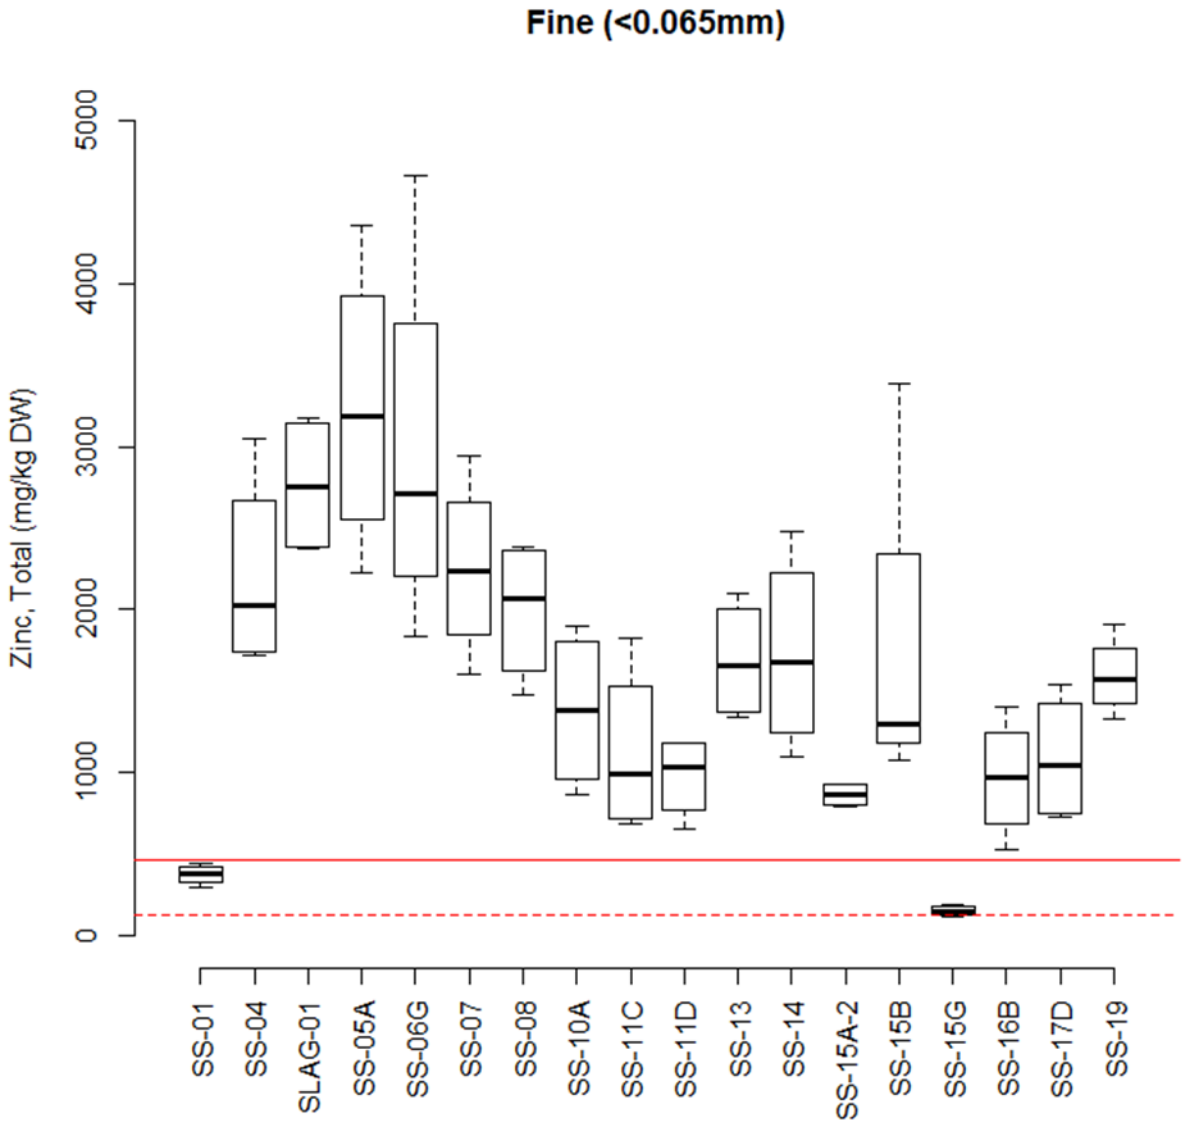

Figure 2-34. Total zinc concentrations in instream sediment (<0.063 mm) samples collected at Streamside Tailings Operable Unit monitoring stations, 2018. Solid red line is the 459 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 121 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

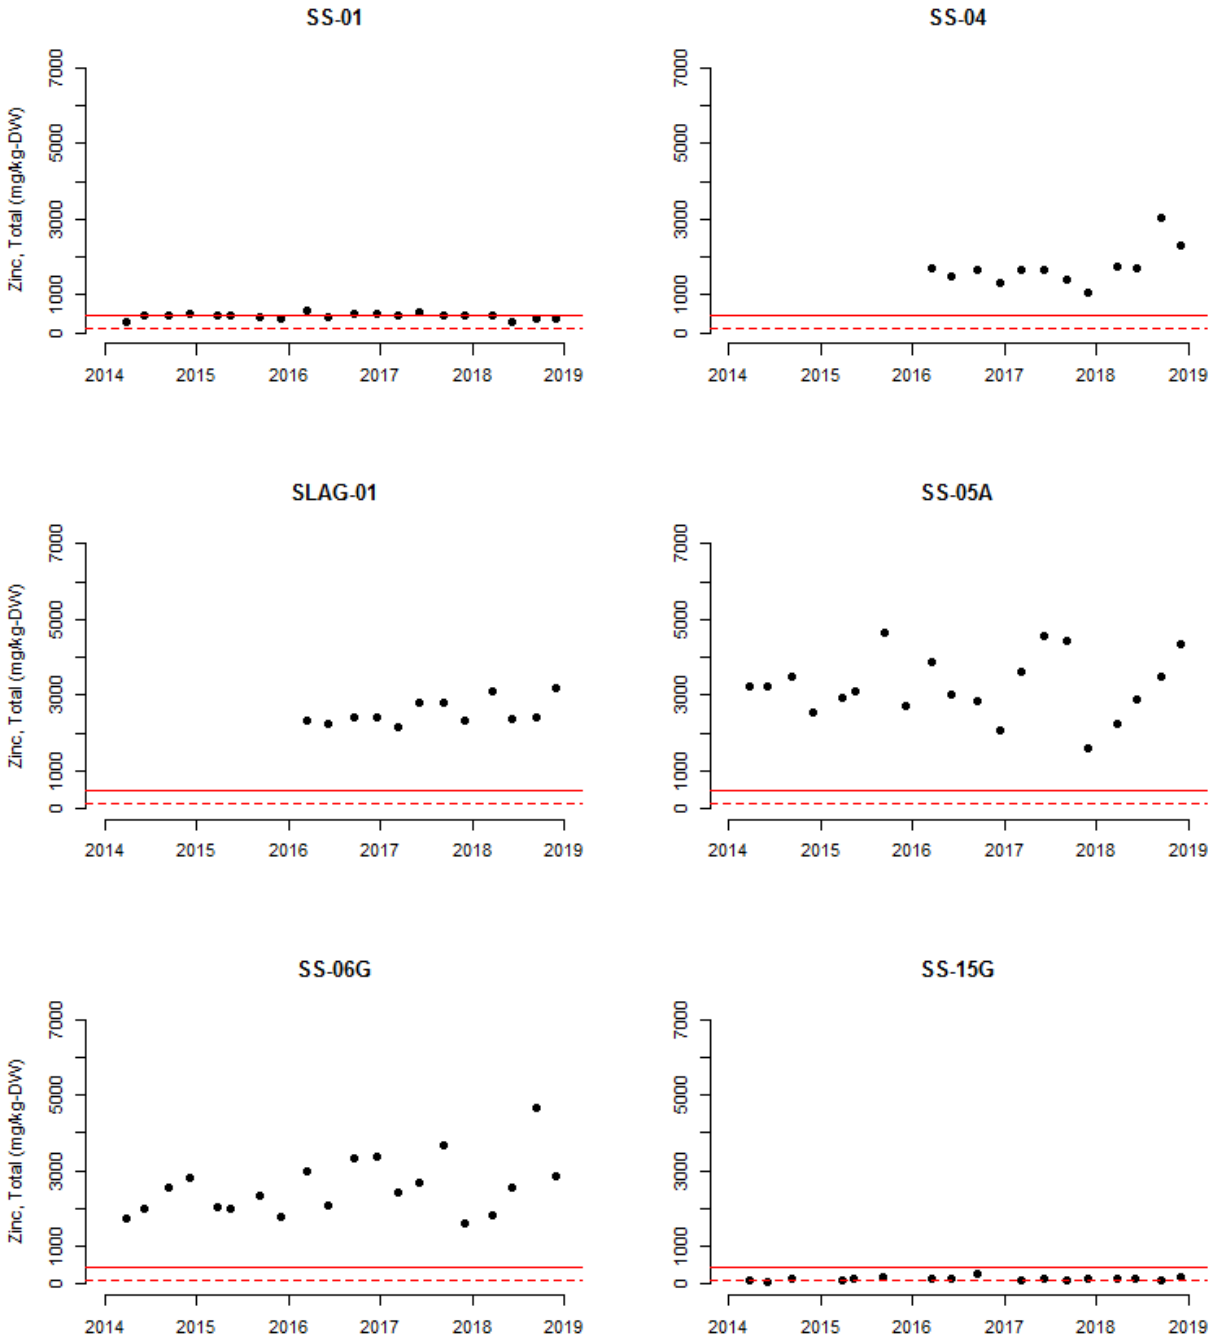

Figure 2-35. Fine fraction (<0.063 mm) total dry-weight zinc concentrations (mg/kg-DW) in Streamside Tailings Operable Unit reference sites: Blacktail Creek at Father Sheehan Park (Site SS-01), Blacktail Creek at Metro Storm Drain Confluence (Site SS-04), Silver Bow Creek in Slag Canyon (SLAG-01), Silver Bow Creek above Butte Reduction Works (Site SS-05A), Silver Bow Creek above Butte WWTP (Site SS-06G), and German Gulch near mouth (Site SS-15G). Solid red line is the 459 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 121 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

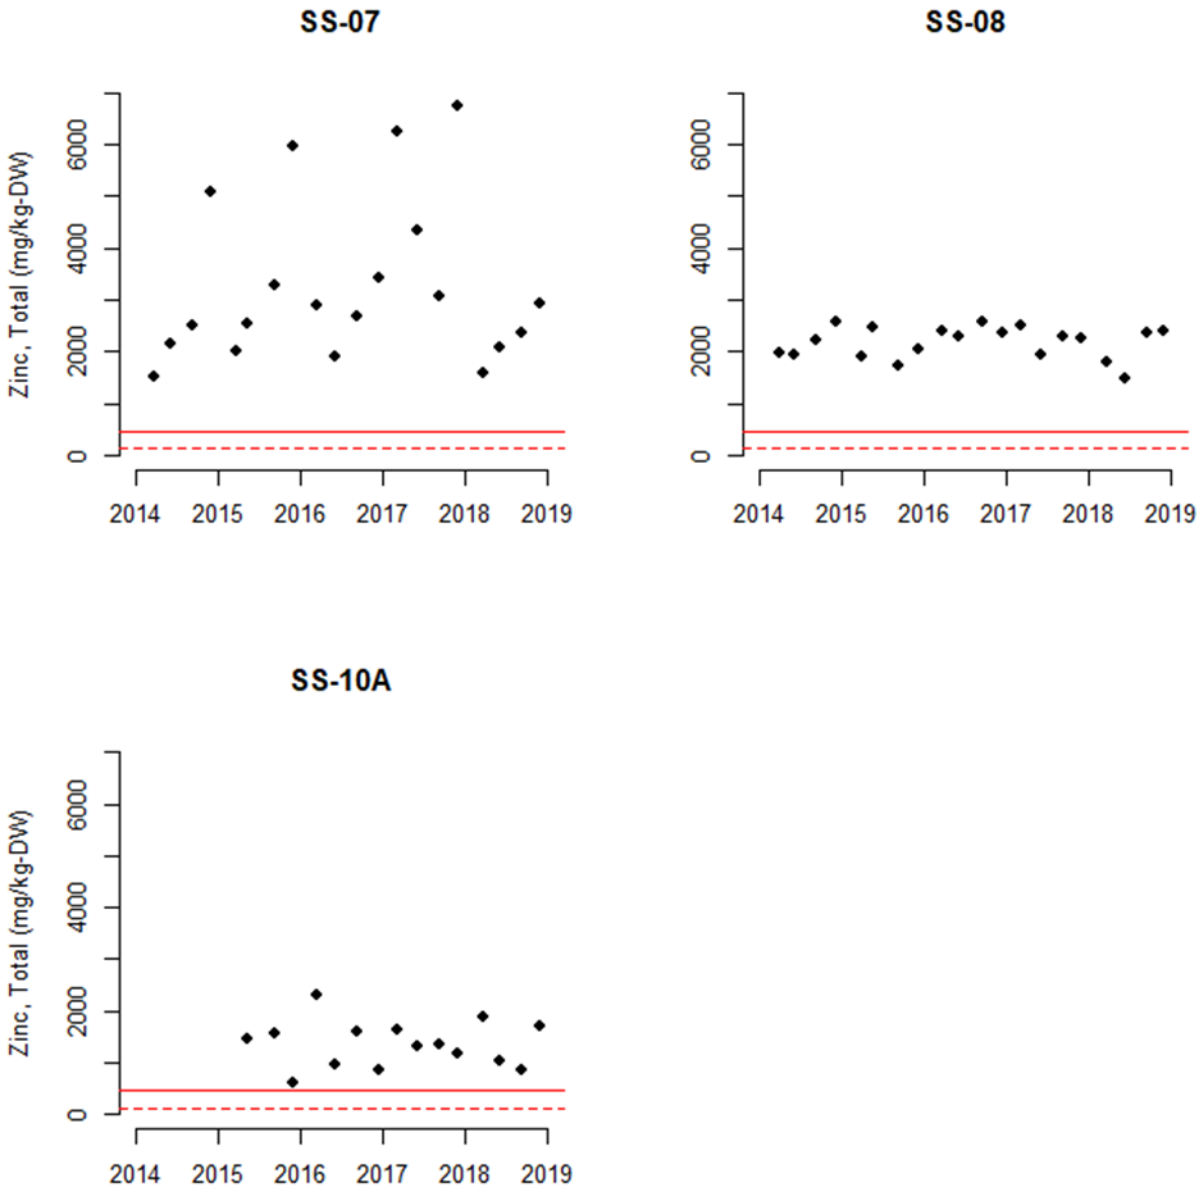

Figure 2-36. Fine fraction (<0.063 mm) total dry-weight zinc concentrations (mg/kg-DW) in Subarea 1 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek below Butte WWTP (Site SS-07), Silver Bow Creek at Rocker (Site SS-08), and Silver Bow Creek above Sand Creek (Site SS-10A). Solid red line is the 459 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 121 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

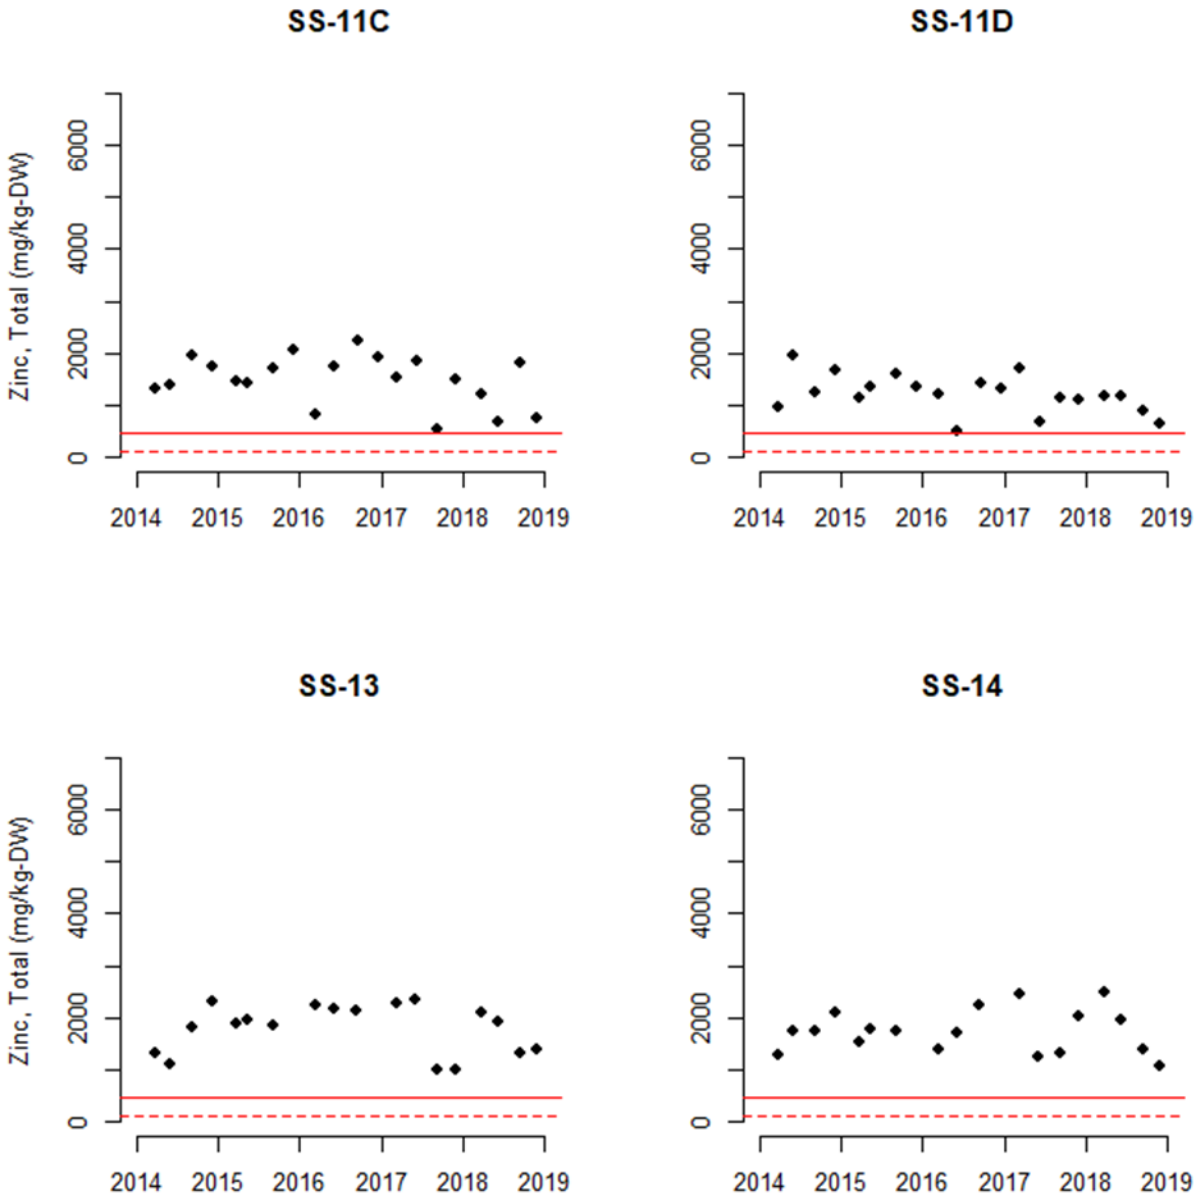

Figure 2-37. Fine fraction (<0.063 mm) total dry-weight zinc concentrations (mg/kg-DW) in Subarea 2 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above (Site SS-11C) and below (Site SS-11D) Browns Gulch, Silver Bow Creek in Reach L (Site SS-13), and Silver Bow Creek at Miles Crossing (Site SS-14). Solid red line is the 459 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 121 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

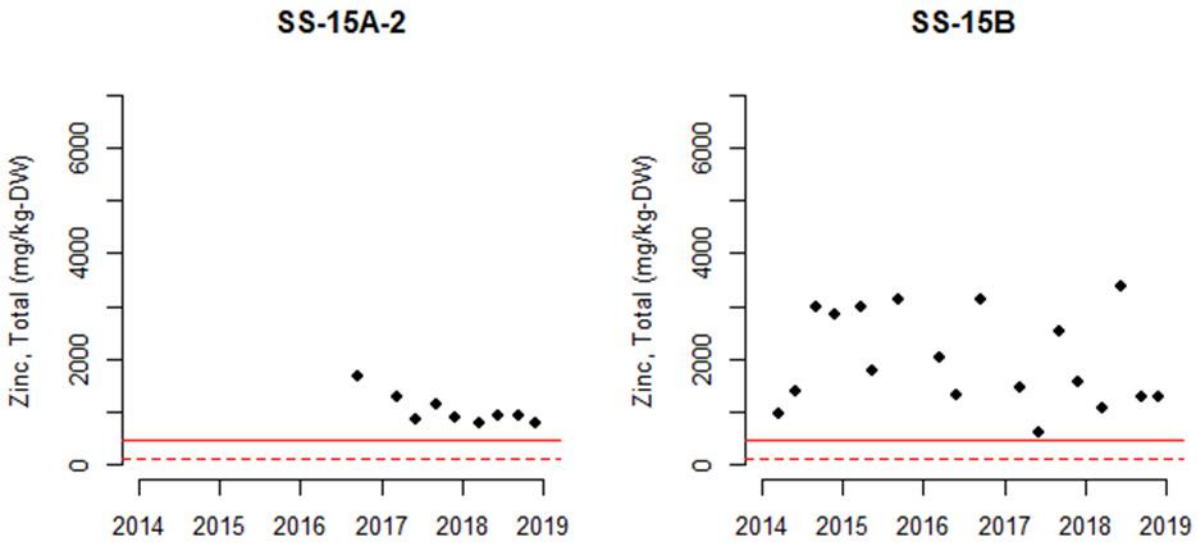

Figure 2-38. Fine fraction (<0.063 mm) total dry-weight zinc concentrations (mg/kg-DW) in Subarea 3 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek above German Gulch (Alternate Site, Site SS-15A-2), Silver Bow Creek above (Site SS-15A) and below (Site SS-15B) German Gulch. Solid red line is the 459 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 121 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

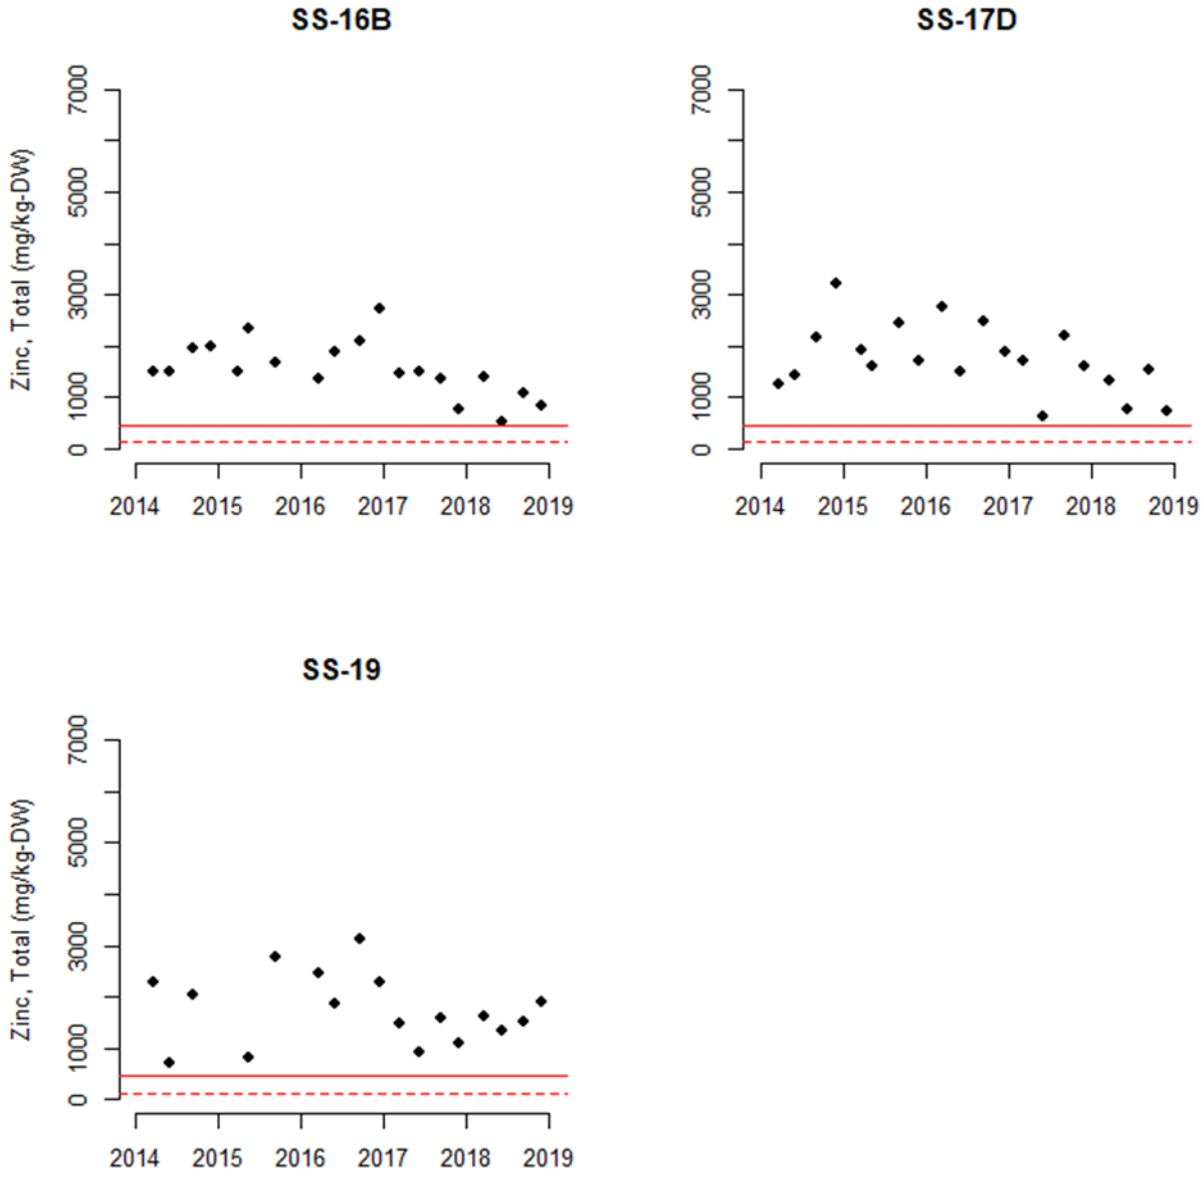

Figure 2-39. Fine fraction (<0.063 mm) total dry-weight zinc concentrations (mg/kg-DW) in Subarea 4 of the Streamside Tailings Operable Unit. Sites include: Silver Bow Creek near Fairmont (Site SS-16B), Silver Bow Creek at Opportunity (Site SS-17D), and Silver Bow Creek at Frontage Road (Site SS-19) [42]. Solid red line is the 459 mg/kg-DW "probable effect concentration" (PEC) and the dashed red line is the 121 mg/kg-DW "threshold effect concentration" (TEC) [MacDonald et al., 2000].

[42] An outlier for Site SS-19 is not shown (15,000 mg/kg during on March 26, 2015).

2.4.3 Other Metals

Summary statistics for non-COC sediment concentrations are presented by sediment size fraction in Table 2-18. Actual sample concentrations for all non-COCs are available in Appendix D. Two of the non-COCs have identified reference values [MacDonald et al., 2000]; chromium and nickel. Therefore, exceedances of the reference values for chromium and nickel are discussed further.

Chromium exceeded the TEC (43.4 mg/kg-DW) in 70 percent (45 of 64) of the samples and exceeded the PEC (111 mg/kg-DW) in 9 percent (6 of 64) of the samples in the fine sediment size fraction (<0.063 mm).

Nickel exceeded the TEC (22.7 mg/kg-DW) in 69 percent (44 of 64) of the samples and exceeded the PEC (48.6 mg/kg-DW) in 13 percent (8 of 64) of the samples in the fine sediment size fraction (<0.063 mm).

Table 2-18. Summary statistics for dry weight (DW) sediment metal concentrations (stratified by size fraction) for samples (*n* = 64) collected in the Streamside Tailings Operable Unit (SSTOU), 2018. No metals in this table are contaminants of concern in the SSTOU.

Metal	Method Detection Limit (mg/kg)		Sample Concentration (mg/kg-DW)			
	Minimum	Maximum	Minimum	Maximum	Mean[43]	Standard Deviation
Fine fraction (<0.063 mm)						
Aluminum	9	40	13,400	41,900	27,381	6,700

Uranium	0.08	0.2	ND	12	1.15	1.51
Vanadium	0.2	2	10	68	16.3	7.5

ND Less than method detection limit.

2.4.4 Data Validation

Data quality objectives (DQOs) were evaluated for sampling precision. Eight paired field sample and field duplicate concentrations were compared to evaluate sampling precision. In each field sample and duplicate pair, 63 comparisons were made; comparisons were made for each pair of 21 metals and in three size fractions (<0.063 mm, 0.063–1 mm, and 1–2 mm). In total, there were 504 sample and duplicate pairs. For each of those pairs, relative percent difference (RPD) comparisons were made. In total, 35 (6.9%) had RPDs greater than the DQO specified for

sampling precision (40%) and at least one of the paired samples had a concentration more than five times higher than the reporting limit.

2.5 DISCUSSION

2.5.1 Sample Size Fraction

Sediment data collected in the SSTOU in 2018 and prior years have demonstrated the sediment size fraction is strongly related (inversely) to most metal concentrations, and these results are consistent with the findings of others [Horowitz and Ehrlick, 1987; Jain and Ram, 1997]. The reason for this relationship between metal concentrations and sediment size fraction is primarily because finer sediments have greater surface area per mass for adsorption of metals [Horowitz and Ehrlick, 1987]. Therefore, when evaluating weighted mean sample concentrations, samples with higher percentages of fine sediments will generally have higher analyte concentrations.

The sample collection method requires that samples are collected and composited from at least five depositional areas, which provides a more representative sample than a sample collected from a single depositional area [DEQ, 2012a]. The weighted mean concentrations have been compared to the reference values (TEC and PEC) to provide the most representative composite sample concentration for all sediments (less than 2 mm) at each site. However, for comparisons of sediment metal concentrations through time (or space), it is more useful to compare concentrations in the same size fractions to eliminate the confounding influence of varying size fraction proportions among disparate samples. Variance in size fractions was high between sites and between sample periods of the same site.

2.5.2 Contaminants of Concern

Prior sampling [RESPEC, 2017a; 2018a] results suggest a major source, or sources, of metal contamination exists in Butte somewhere between Blacktail Creek at Father Sheehan Park (Site SS-01) and Silver Bow Creek above the Butte Reduction Works (Site SS-05A). In 2016, additional sample sites were added between Sites SS-01 and SS-05A above the Metro Storm Drain (Site SS-04) and in Slag Canyon (SLAG-01) to identify potential sources. At each site, sediments were analyzed in only the fine (<0.063 mm) fraction and only for the COCs, excluding mercury.

Data from 2016-2018 demonstrate substantial COC loading between each of these sites (Sites SS-01, SS-04, SLAG-01, and SS-05A). In 2016 and 2017, loading appeared to occur primarily in the reach between the Metro Storm Drain and the lower end of the Slag Canyon (between Sites SS-04 and SS-05A) but in 2018 concentrations at the uppermost of those sites (Site SS-04) were elevated and therefore the precise location of the sources is less clear. We recommend continued monitoring of Sites SS-04 and SLAG-01 to provide more data for these sites and potentially,

additional monitoring sites to add finer resolution in the lower portion of Blacktail Creek and the vicinity of the Metro Storm Drain and Slag Canyon.

Downstream from Site SS-05A, arsenic, copper, lead, and zinc concentrations generally decreased sequentially at each downstream site through Subarea 1 to Sand Creek (Site SS-10A). Analyte concentrations tended to increase downstream from Sites SS-10A to SS-19 although the increases between sites were not large or consistent among COCs or size fractions, and deviations from that trend were common.

Remediation is now complete throughout Subarea 3 although Site SS-15B continued to demonstrate elevated COC concentrations. Limited tailings in the streambed and streambanks in the immediate upstream vicinity of Site SS-15B were likely responsible for the elevated concentrations. Those tailings were left to naturally attenuate because access was limited and the volume of tailings in this reach is relatively low. Samples collected immediately upstream of the remnant tailings (at Site SS-15A-2), had substantially lower COC concentrations compared to Site SS-15B. Concentrations at Site SS-15A-2 were similar to concentrations in Subarea 2 sites which ware generally quite low.

Time series data from 2014-2018 suggest monotonic trends may be occurring for some COCs at specific locations. In background and reference sites located in Silver Bow and Blacktail Creeks upstream from the SSTOU, some COC concentrations at certain sites appear to be increasing slightly through time. In Subareas 3 and 4, most sites demonstrate evidence of declining COC concentrations through time.

2.5.3 Data Validation

Some DQOs were exceeded for sampling precision. Of the 504 field sample and field duplicate pairs compared, 35 exceeded the specified DQO for sampling precision (relative percent different of the field sample and field duplicate was greater than 40 percent). All associated data will be "J" flagged in the project database as described in the quality assurance project plan [RESPEC, 2014].

3.0 GROUNDWATER

3.1 INTRODUCTION

This chapter describes groundwater-monitoring data collected in 2018 to assess the effectiveness of remedial actions implemented in the Streamside Tailings Operable Unit (SSTOU) of the Silver Bow Creek/Butte Area National Priorities List site. Data were collected to evaluate the effects of remedial actions on groundwater quality and progress toward attainment of performance goals. Groundwater contamination is among the environmental concerns for Silver Bow Creek and may pose a threat to human health and the environment. A remediation objective in the SSTOU is to reduce loading of contaminants from floodplain soils to groundwater and surface water.

3.2 PERFORMANCE GOALS

The SSTOU Record of Decision (ROD) specifies that the final remediation standards for concentrations of contaminants of concern (COC) in groundwater are to "attain compliance with applicable Circular WQB-7 standards, federal MCLs (maximum contaminant levels) and federal nonzero maximum contaminant level goals (MCLGs) for all SSTOU groundwater." Moreover, "the groundwater levels to be attained consist of the more stringent of the MCL, any nonzero MCLG, or the WQB-7 human health standard for each parameter." While more stringent standards promulgated since the issuance of the ROD have not yet been formally adopted as performance standards for this operable unit, this monitoring report uses the more stringent of the ROD's Circular WQB-7 standards [MDHES, 1994] or current Montana Department of Environmental Quality (DEQ) Circular DEQ-7 standards [DEQ, 2017] as the goal to be attained for evaluation purposes. The most stringent of these standards for each COC is shown in Table 3-1. The DEQ [2017] human health groundwater standards for non-COC metals are summarized in Table 3-2.

Table 3-1. Comparison of the Montana groundwater standards in July 1994 (effective at the time of issuance of the Streamside Tailings Operable Unit Record of Decision) and May 2017 (effective in 2017) for each contaminant of concern.

Contaminant of Concern	Human Health Groundwater Standard (mg/L)	
	MDHES [1994]	DEQ [2017]
Arsenic	0.018	0.010
Cadmium	0.00500	0.00500
Copper	1.000	1.300
Lead	0.0150	0.0150
Mercury	0.00014	0.00200
Zinc	5.0	2.0

Gray cells identify the most restrictive standard.

Table 3-2. Montana groundwater standards for metals that are not contaminants of concern in the Streamside Tailings Operable Unit [DEQ, 2017].

Metal	Human Health Groundwater Standard (mg/L)

Silver	0.1
Uranium	0.03
Vanadium	–

3.3 METHODS

The purpose of the groundwater-monitoring program is to collect data that describe temporal and spatial variation in metal and ion concentrations for groundwater in the SSTOU. These data provide a long-term record of environmental conditions in the SSTOU. As of 2018, 17 years of SSTOU groundwater data (2002–2018) have been collected under this monitoring program. This long-term record provides data to evaluate the effects of remediation on environmental conditions

in the SSTOU over time. Improvement to groundwater quality may require long time periods (i.e., decades) following completion of remediation within the SSTOU.

Changes to the groundwater monitoring program have occurred over time and a record of these changes is provided in the program sampling and analysis plan [RESPEC, 2018b]. The program attempts to adhere to monitoring requirements specified in the SSTOU ROD (Table 3-3).

3.3.1 Monitoring Locations

In 2018, monitoring occurred in nine well clusters within the SSTOU. Major remediation was completed in all subareas prior to 2018, but minor remedial actions were in progress in Subarea 2 to remove some remnant tailings (Figure 3-1; Table 3-4). Each well cluster consisted of three wells: two monitoring wells located within the stream floodplain and one background well located outside the floodplain and adjacent to the monitoring wells. Well cluster locations were selected based on SSTOU ROD requirements (Table 3-3).

The Mine Waste Relocation Repository (MWRR) well cluster is located outside of the floodplain at a site where approximately 171,900 cubic yards of contaminated soil from Reach A of Subarea 1 were deposited [USEPA, 2011]. The MWRR site consists of five monitoring wells and one background well, which is located up-gradient from the MWRR.

Table 3-3. Minimum post-remedy monitoring requirements specified in the Record of Decision for the Streamside Tailings Operable Unit [DEQ and USEPA, 1995].

[44] Well GW-WG-NS was installed in 2016 to replace Well P-06A (45.99940, –112.57622), which was discontinued.

[45] Well GW-WG-SS was installed in 2016 to replace Well GW-1052R (45.99916, –112.57622), which was discontinued.

3.3.2 Monitoring Schedule

Groundwater was monitored during low streamflow periods from October 2-4, 2018, to describe spatial variation in shallow groundwater chemistry within the SSTOU. At the MWRR well cluster monitoring also occurred during the runoff period on July 12, 2018.

3.3.3 Monitoring Parameters

Groundwater samples were analyzed for the parameters and analytes listed in Table 3-5.

Table 3-5. Sampling parameters and analytes for groundwater monitoring of the Streamside Tailings Operable Unit.

Parameter	Analytes
Concentrations of dissolved metal COCs	Arsenic, cadmium, copper, lead, mercury, zinc
Concentrations of other dissolved metals	Aluminum, antimony, barium, beryllium, boron, cobalt, chromium, iron, manganese, molybdenum, nickel, selenium, silver, uranium, vanadium
Common ion concentrations	Sulfate, total alkalinity, bicarbonate alkalinity, calcium, magnesium, sodium, potassium, chloride, hardness
Other physical properties	Water temperature, pH, specific conductivity

3.3.4 Sample Collection and Analysis

Sample collection and analysis procedures are described in the project sampling and analysis plan (SAP) [RESPEC, 2018b] and quality assurance and quality control (QA/QC) procedures are described in the program quality assurance project plan (QAPP) [RESPEC, 2014]. Sample collection methods generally followed standard operating procedures (SOPs) developed for the Clark Fork River [AR, 1992]. Field sampling procedures were in accordance with DEQ [2012a] and followed "clean hands/dirty hands" procedures described in USGS [2006]. Dedicated or disposable well bailers were used in low yield wells where installing a submersible pump was impractical. Field parameters (i.e., water temperature, pH, dissolved oxygen concentration, and conductivity) were measured during each monitoring event with a field multimeter (YSI Professional Plus). Dissolved metal samples were filtered in the laboratory rather than in the field because some wells had high levels of suspended sediment, which made field filtering impractical. Samples were analyzed by Energy Laboratories (Helena, Montana). Laboratory analysis procedures for each analyte are presented in Table 3-6.

Table 3-6. Analytes, methods, and reporting limits for groundwater sampling in the Streamside Tailings Operable Unit.

Analyte	Requested Method	Requested Reporting Limit (mg/L)[46]	Holding Time (days)	Bottle	Preservative[47]

[46] Requested reporting limits are either the required reporting limit of DEQ [2017] or the lowest reporting limit previously provided by the analytical laboratory, which is lower.

[47] All groundwater samples were preserved in the laboratory.

3.3.5 Data Analysis

3.3.5.1 Metal Contaminants of Concern

For each sample, the concentration for each metal COC in 2018 was compared to the Montana groundwater standards (Table 3-1). To provide the temporal trend for each COC concentration in each well, all COC concentrations throughout the monitoring period of record were also plotted through time. In each well cluster, COC concentrations were grouped according to the well purpose (i.e., background or monitoring), and narrative discussions are focused on comparing the conditions in the background wells to those observed in the monitoring wells in each cluster.

3.3.5.2 Other Metals and Common Ions

Concentrations of non-COC metals and common ions from 2018 were tabulated. Sample concentrations are compared to DEQ [2017] groundwater standards for those metals with standards.

3.3.6 Data Validation

Data quality objectives were established in the SSTOU monitoring project QAPP for data representativeness, comparability, completeness, sensitivity, precision, bias, and accuracy [RESPEC, 2014]. Methods for field and laboratory quality assurance and quality control procedures are also described in detail in the project QAPP [RESPEC, 2014]. A completed checklist, summary tables of field-duplicate and field-blank results, and assessments of data quality objectives are included in Appendix A.

3.4 RESULTS

3.4.1 Mine Waste Relocation Repository

3.4.1.1 Contaminants of Concern

In both July and October 2018, one MWRR monitoring well had an arsenic concentration slightly exceeding the DEQ groundwater standard: Well LYP-07 exceeded the arsenic standard in July and Well MW-2B exceeded the arsenic standard in October (Table 3-7). No other MWRR monitoring wells had samples with metal COC concentrations exceeding any DEQ groundwater standard (Table 3-7). During both quarters, the background well (Well MW-2A) in the MWRR cluster had an arsenic concentration that was at or slightly above the arsenic groundwater standard (Table 3-7), but no other COCs exceeded standards in the background well.

Table 3-7. Dissolved metal contaminant of concern concentrations (mg/L) in groundwater monitoring wells of the Mine Waste Relocation Repository in the Streamside Tailings Operable Unit, 2018.

J	Estimated because: (1) result is between method detection limit and analytical reporting limit, or (2) relative percent difference of associated field sample and duplicate pair was above project-specific data quality objective (25%).
	Exceeds human health groundwater standard [DEQ, 2017].

3.4.1.1.1 Arsenic

Arsenic concentrations in the MWRR have been generally consistent at each well since monitoring began in 2006 (Figure 3-2). All monitoring wells have had arsenic concentrations that were less than, or similar to, the background well concentration throughout the period of record (Figure 3-2). Data do not indicate an increasing trend at any well, with the possible exceptions of Wells MW-2B and 1GW-1056 (Figure 3-2). Well MW-2B appears to have a slightly increasing trend through time, although concentrations have not exceeded those in the background well during any sample period (Figure 3-2). Similarly, Well 1GW-1056 may have had an increasing trend since approximately 2013, but concentrations have not exceeded those in the background well during any sample period (Figure 3-2).

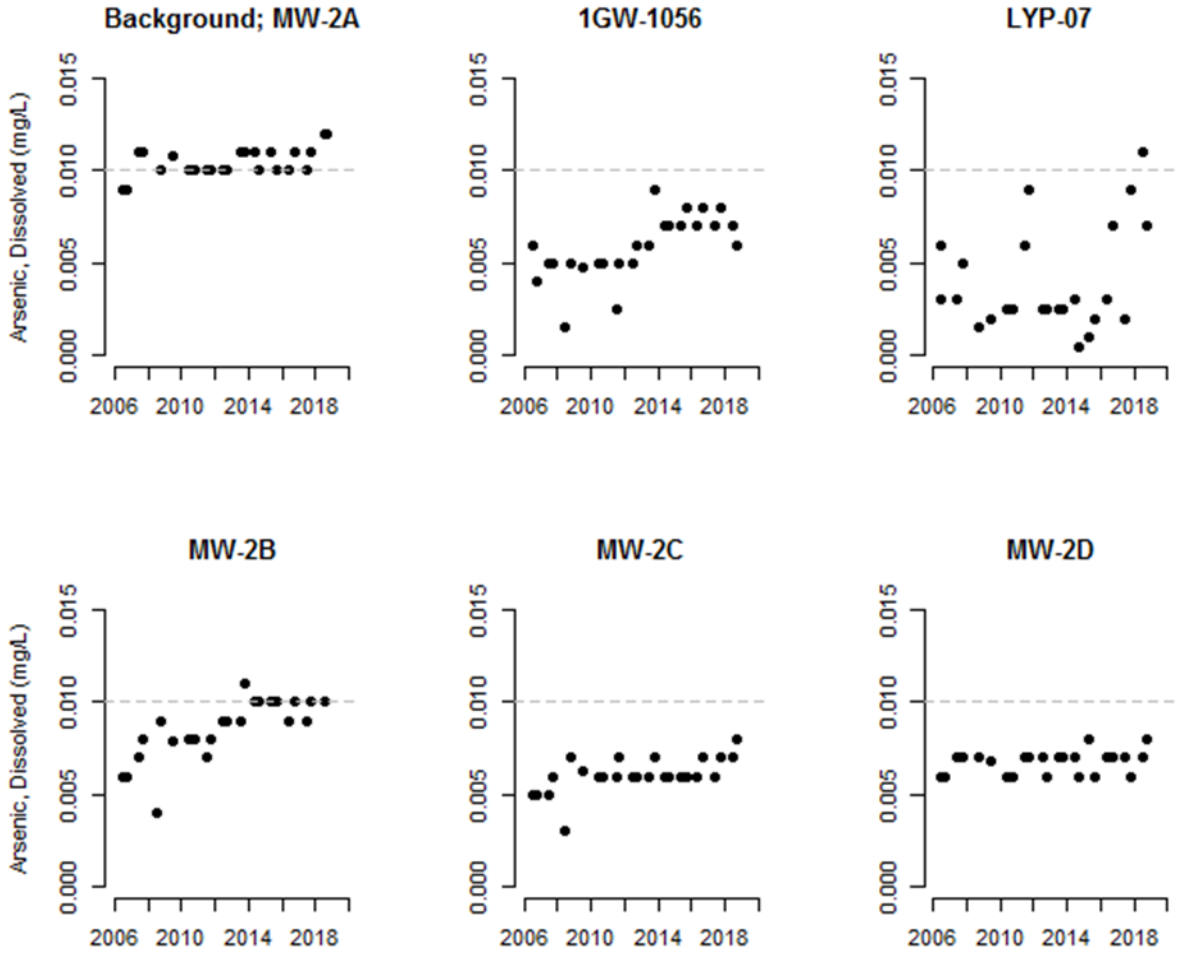

Figure 3-2. Arsenic concentrations in groundwater wells in the Mine Waste Relocation Repository in the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [DEQ, 2017].

3.4.1.1.2 Cadmium

Based on the monitoring period of record in the MWRR, all samples had cadmium concentrations well below the most restrictive groundwater standard (Figure 3-3). There is no evidence that cadmium concentrations are increasing through time in any of the MWRR wells (Figure 3-3).

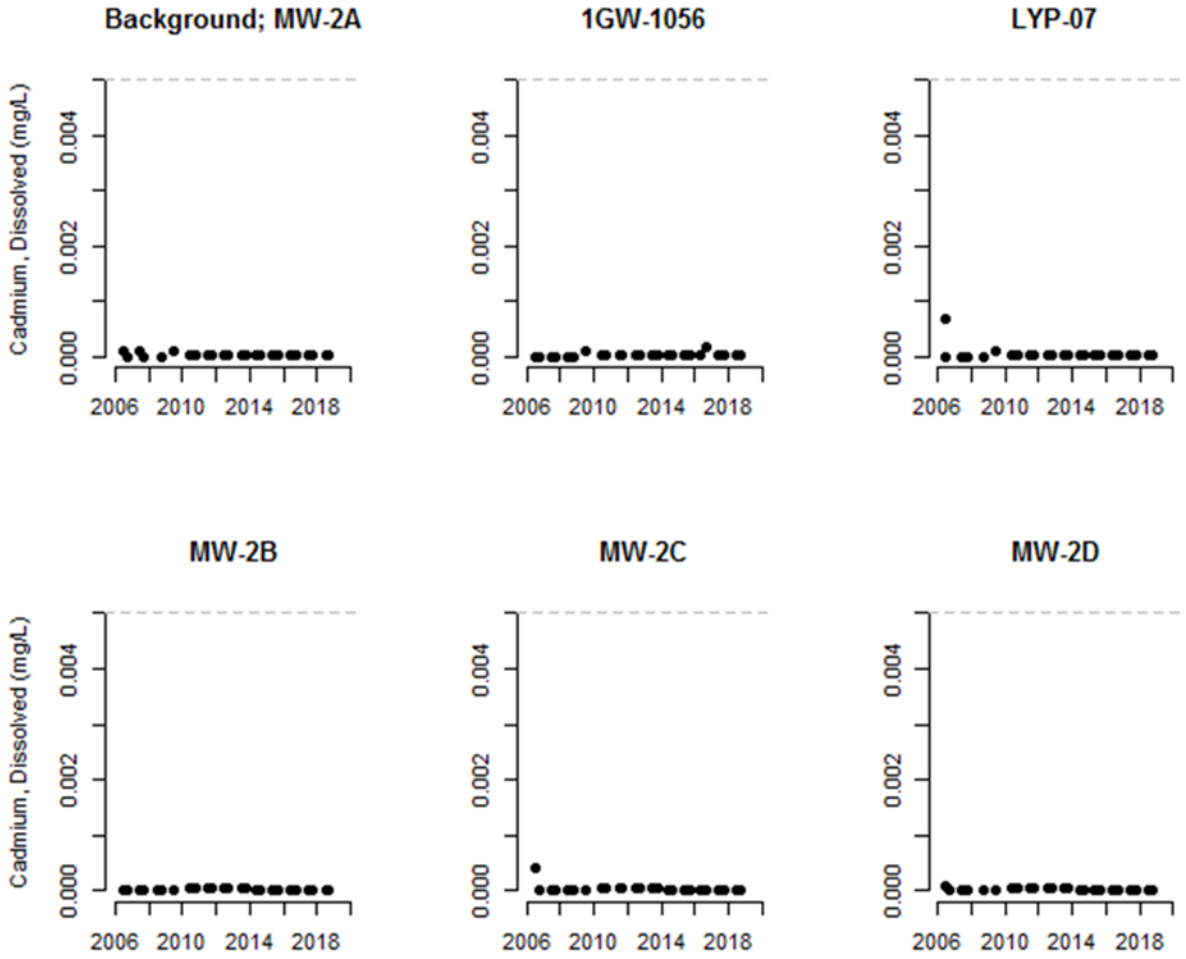

Figure 3-3. Cadmium concentrations in groundwater wells in the Mine Waste Relocation Repository in the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [DEQ, 2017].

3.4.1.1.3 Copper

Based on the monitoring period of record in the MWRR, all samples had copper concentrations well below the most restrictive groundwater standard (Figure 3-4). There is no evidence that copper concentrations are increasing through time in any of the MWRR wells (Figure 3-4).

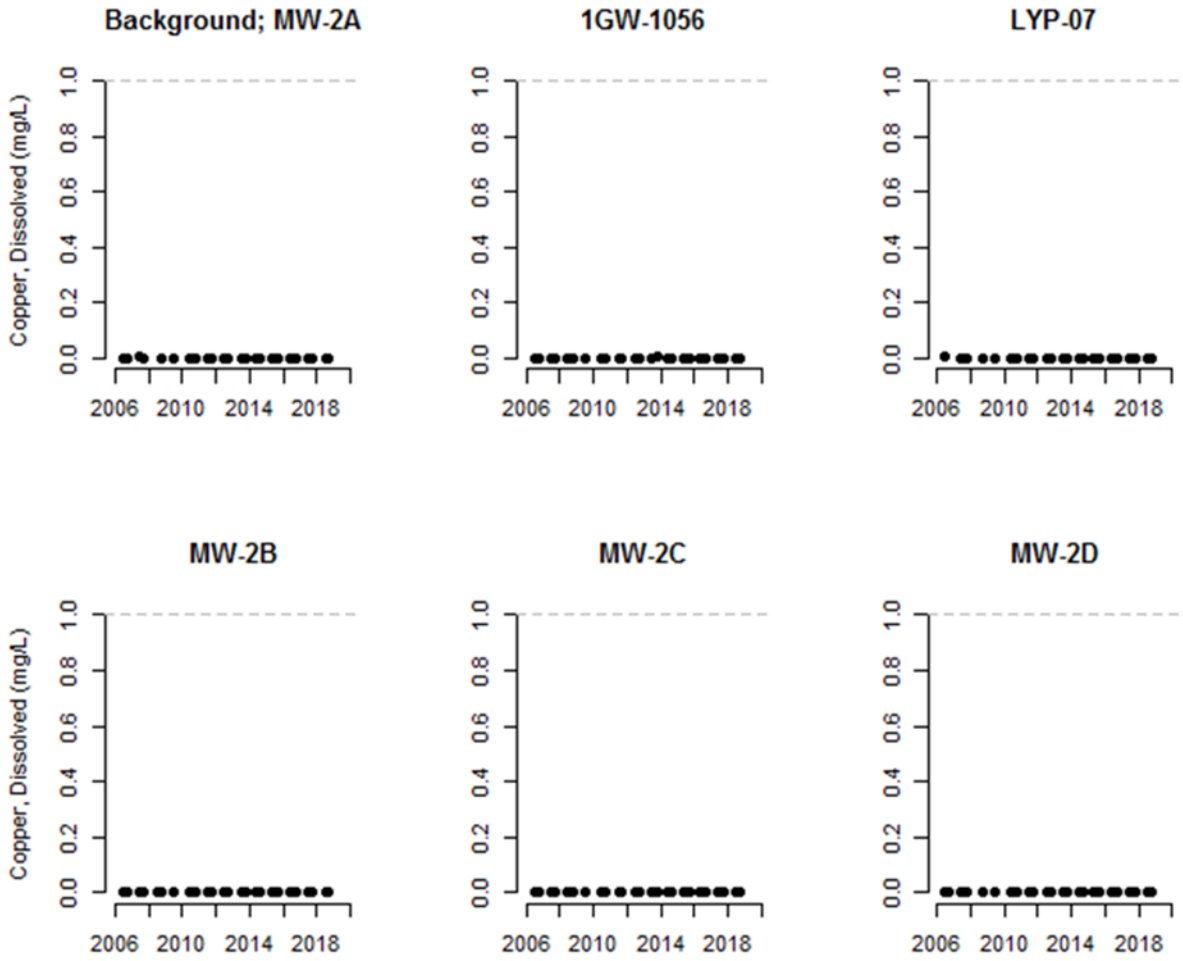

Figure 3-4. Copper concentrations in groundwater wells in the Mine Waste Relocation Repository in the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [MDHES, 1994].

3.4.1.1.4 Lead

Based on the monitoring period of record in the MWRR, all lead concentrations were well below the most restrictive groundwater standard (Figure 3-5). There is no evidence that lead concentrations are increasing in any monitoring wells (Figure 3-5).

Figure 3-5. Lead concentrations in groundwater wells in the Mine Waste Relocation Repository in the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [DEQ, 2017].

3.4.1.1.5 Mercury

Based on the monitoring period of record in the MWRR, all mercury concentrations were near or below the analytical reporting limit during all sample periods (Figure 3-6). There is no evidence that mercury concentrations are increasing in any monitoring wells (Figure 3-6). Nearly all sample variance in Figure 3-6 was from variance in the reporting limit.

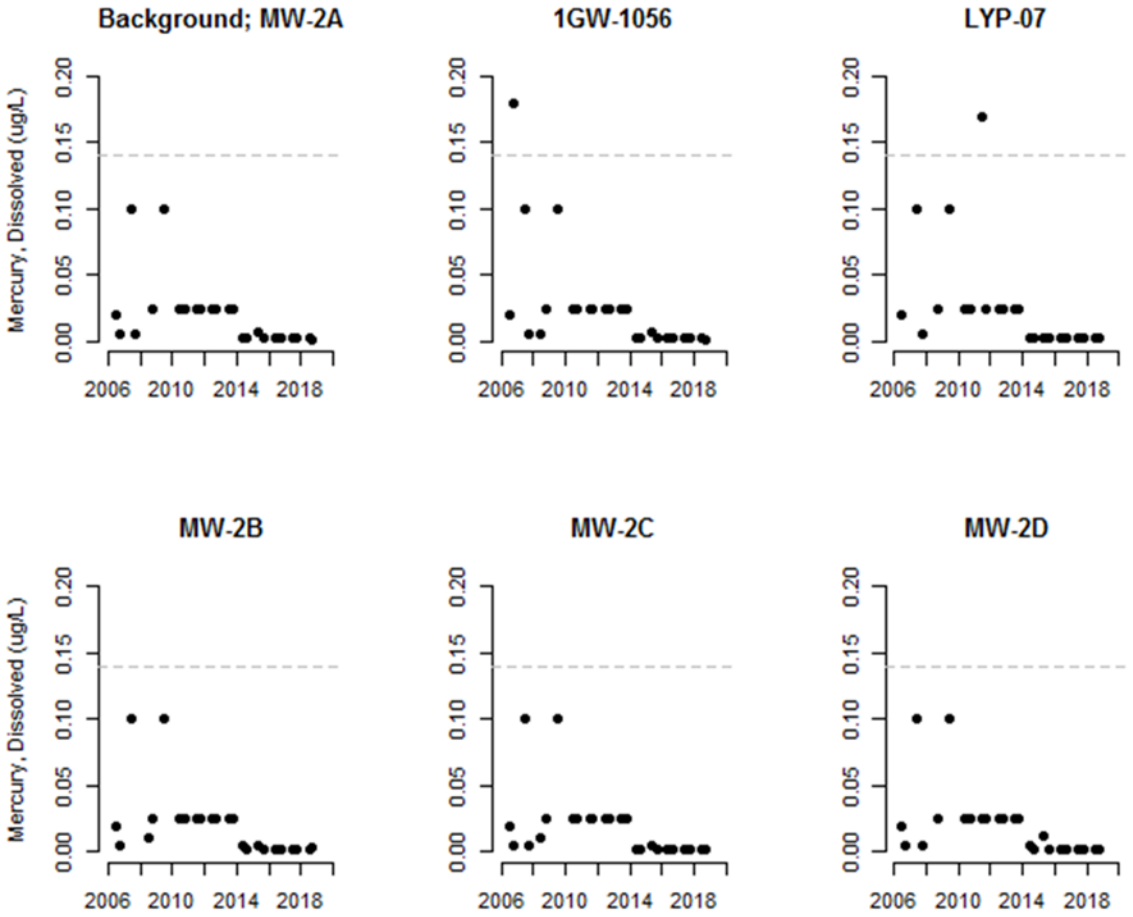

Figure 3-6. Mercury concentrations in groundwater wells in the Mine Waste Relocation Repository in the Streamside Tailings Operable Units (2006–2018). Gray dashed line represents the human health groundwater standard [MDHES, 1994]. Samples with concentrations below the analytical reporting limit are represented at half the reporting limit.

3.4.1.1.6 Zinc

Based on the monitoring period of record in the MWRR, all zinc concentrations were well below the most restrictive groundwater standard (Figure 3-7). There is no evidence that zinc concentrations are increasing in any monitoring wells (Figure 3-7).

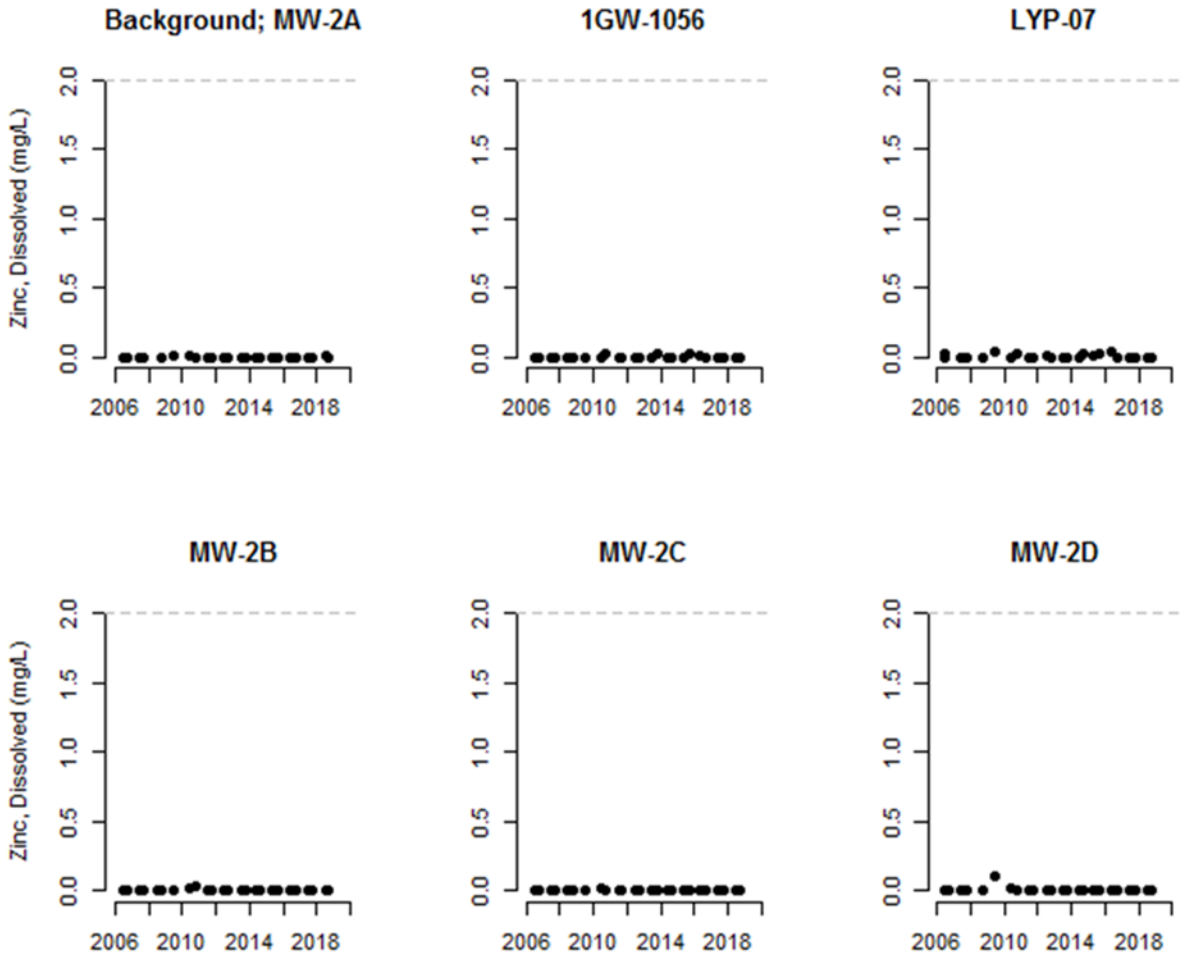

Figure 3-7. Zinc concentrations in groundwater wells in the Mine Waste Relocation Repository in the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [DEQ, 2017].

3.4.1.2 Other Metals

In the MWRR in 2018, uranium concentrations exceeded the 0.030 mg/L DEQ [2017] standard in the background well (Well MW-2A) and in three monitoring wells (Wells 1GW-1056, LYP-07, and MW-2D) in June and October (Table 3-8). No other non-COC metals exceeded the DEQ [2017] standards in any MWRR wells in 2018.

3.4.1.3 Common Ions

Common ion concentrations in the MWRR wells for 2018 are presented in Table 3-9.

Table 3-8. Dissolved metal (non-contaminant of concern) concentrations (mg/L) in Mine Waste Relocation Repository groundwater monitoring wells in the Streamside Tailings Operable Unit, 2018.

* Background well.

3.4.2 Floodplain

3.4.2.1 Contaminants of Concern

In the Silver Bow Creek floodplain monitoring wells in 2018, five of six COCs had concentrations that exceeded the most restrictive human health groundwater standard in MDHES [1994] or DEQ [2017] in at least one well (Table 3-10). Six wells exceeded the arsenic standard and three of these were background wells (Table 3-10). Seven floodplain monitoring wells in five separate well clusters exceeded the cadmium standard, but no background wells exceeded the standard (Table 3-10). One sample from a monitoring well in the Stuart Cluster exceeded the copper standard (Table 3-10). One sample from a monitoring well in the Nissler cluster exceeded the lead standard (Table 3-10). Seven floodplain monitoring wells, in four separate well clusters, exceeded the zinc standard but no background wells exceeded the standard (Table 3-10). These results are similar to previous years.

3.4.2.1.1 Arsenic

Based on the monitoring period of record in the Silver Bow Creek floodplain, arsenic concentrations in all Subarea 1 floodplain monitoring wells were similar to the concentrations in the background well during all monitoring periods except for Well MW-01. Well MW-01 had one elevated sample in 2014 (Figure 3-8). In Subarea 2, arsenic concentrations appear to have been slightly higher in both monitoring wells of the Silver Bow Cluster, particularly in P-39R (Figure 3-9). In the Miles Crossing Cluster (Subarea 2), the background well (Well GW-MC-BG) has consistently had the highest concentrations of any well in the SSTOU monitoring network (Figure 3-8; Figure 3-9; Figure 3-10). Subarea 4 monitoring wells all had arsenic concentrations that were similar to or lower than concentrations in the background well (Figure 3-10).

Table 3-10. Dissolved metal (contaminant of concern) concentrations (mg/L) in groundwater monitoring wells located along Silver Bow Creek in the Streamside Tailings Operable Unit, October 2018.

Gray dashed line represents the human health groundwater standard [DEQ, 2017]. Each row of plots represents a well cluster: Fairmont Cluster, Crackerville Cluster, Stuart Cluster, and Frontage Road Cluster.

3.4.2.1.2 Cadmium

Based on the monitoring period of record in the Silver Bow Creek floodplain, cadmium concentrations in all Subarea 1 floodplain monitoring wells were similar to the concentrations in the background well except for Well P-58A (Nissler Cluster), which had higher cadmium concentrations relative to the background well in the same cluster (GW-1003R) (Figure 3-11). In Subarea 2, cadmium concentrations have been elevated relative to the background well in two monitoring wells: Well P-37A (Silver Bow Cluster) and Well GW-MC-NS (Miles Crossing Cluster) (Figure 3-12). However, all samples from Well P-37A since 2013 have been relatively low compared to the 2006–2012 period (figure 3-12). In Subarea 4, both monitoring wells located in the Stuart Cluster (Wells GW-ST-ES and GW-ST-WS) and one monitoring well located in the Crackerville Cluster (Well GW-CR-ES) have had elevated concentrations relative to the background wells (Figure 3-13).

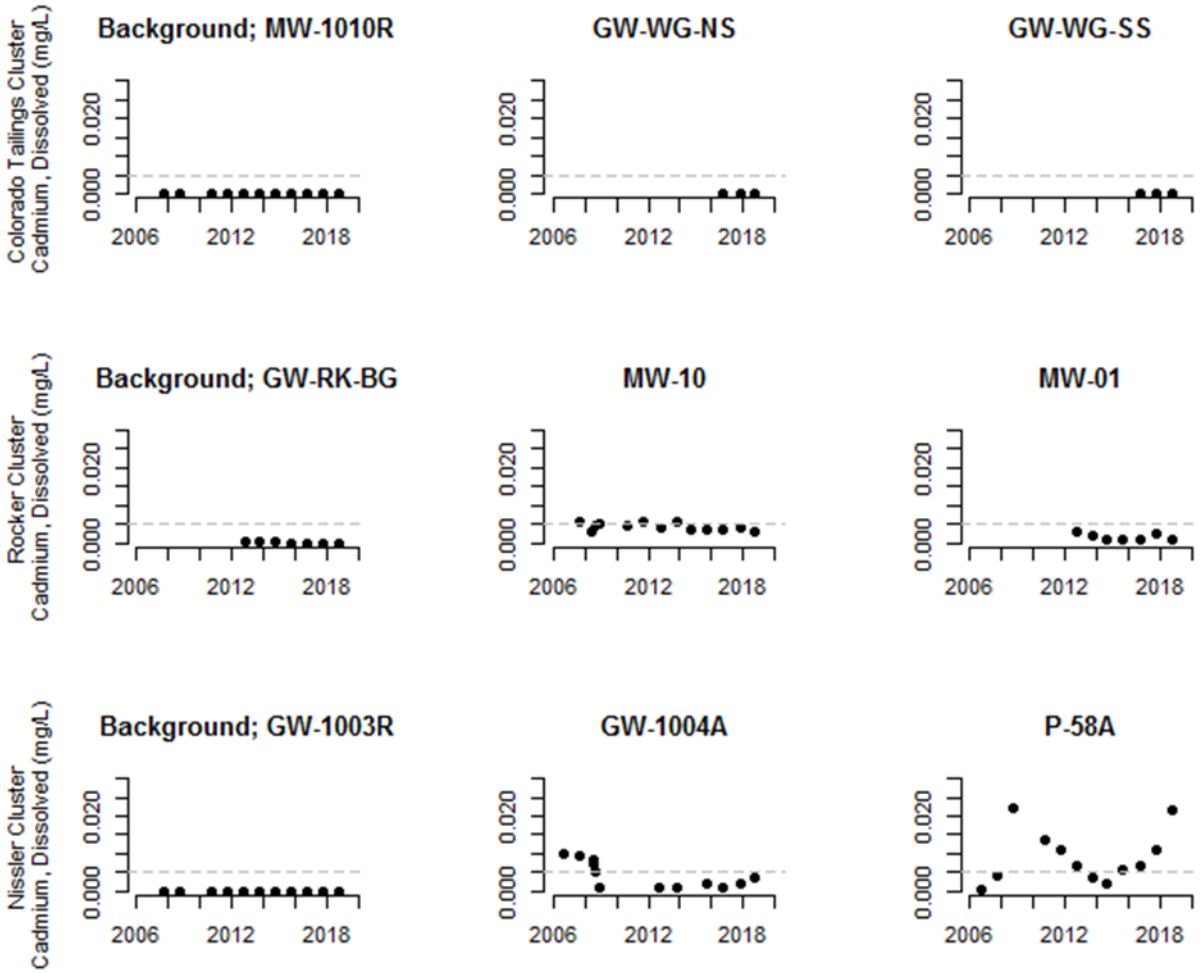

Figure 3-11. Cadmium concentrations in groundwater wells located in Subarea 1 of the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [DEQ, 2017]. Each row of plots represents a well cluster: Colorado Tailings Cluster, Rocker Cluster, and Nissler Cluster.

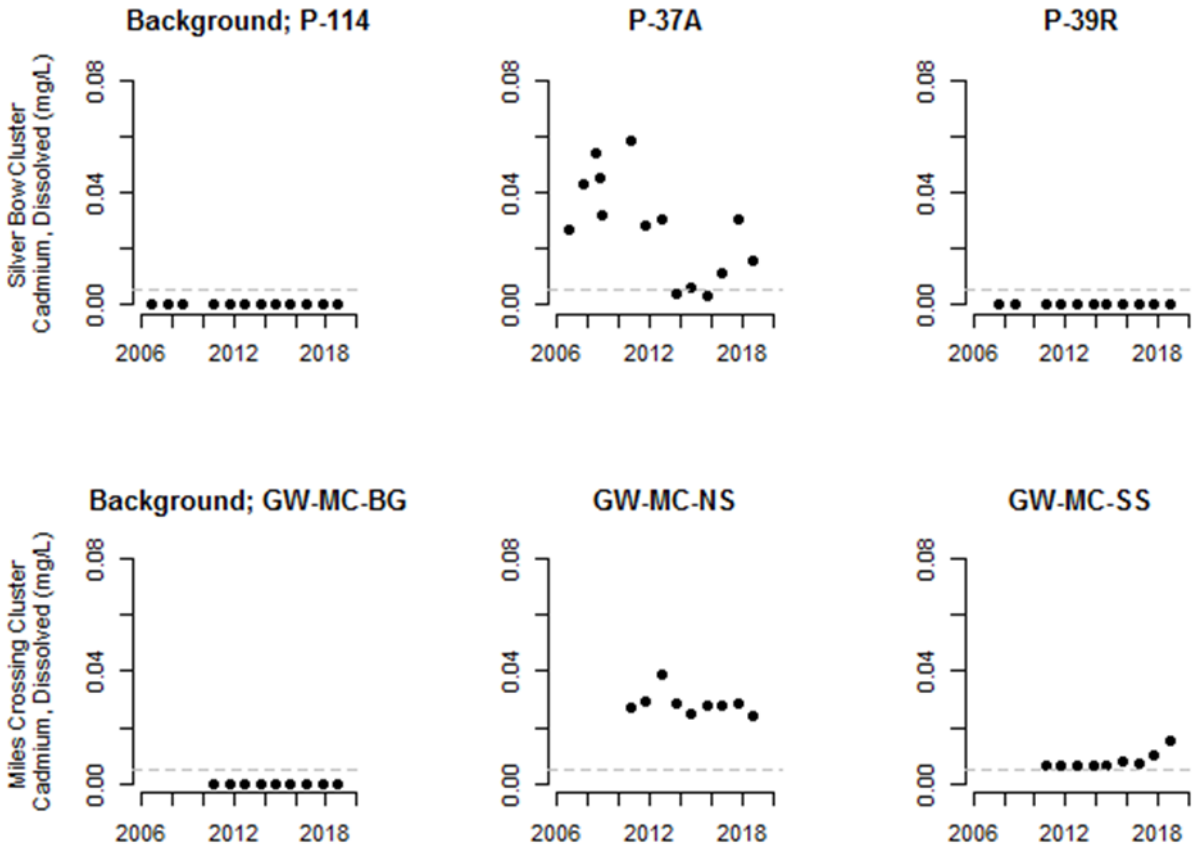

Figure 3-12. Cadmium concentrations in groundwater wells located in Subarea 2 of the Streamside Tailings Operable Unit (2006–2018). Figure 3-13. Cadmium concentrations in groundwater wells located in Subarea 4 of the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [DEQ, 2017]. Each row of plots represents a well cluster: Fairmont Cluster, Crackerville Cluster, Stuart Cluster, and Frontage Road Cluster.

3.4.2.1.3 Copper

Based on the monitoring period of record in the Silver Bow Creek floodplain, copper concentrations in floodplain monitoring wells were elevated relative to the background well in the Subarea 1 floodplain monitoring wells (Figure 3-14). Concentrations in some Subarea 1 wells have been variable (Wells MW-10 and P-58A) (Figure 3-14). In Subarea 2, copper concentrations were elevated relative to the background well in Well GW-MC-NS (Miles Crossing Cluster) (Figure 3-15). However, concentrations in Well GW-MC-NS appear to be decreasing substantially through time (). In Subarea 4, both of the wells located in the Stuart Cluster (Wells GW-ST-ES and GW-ST-WS) had elevated copper concentrations relative to the background well (Figure 3-16). Concentrations in Well GW-ST-ES have exceeded the MDHES [1994] groundwater standard during all of the sample periods (2013–2018) (Figure 3-16).

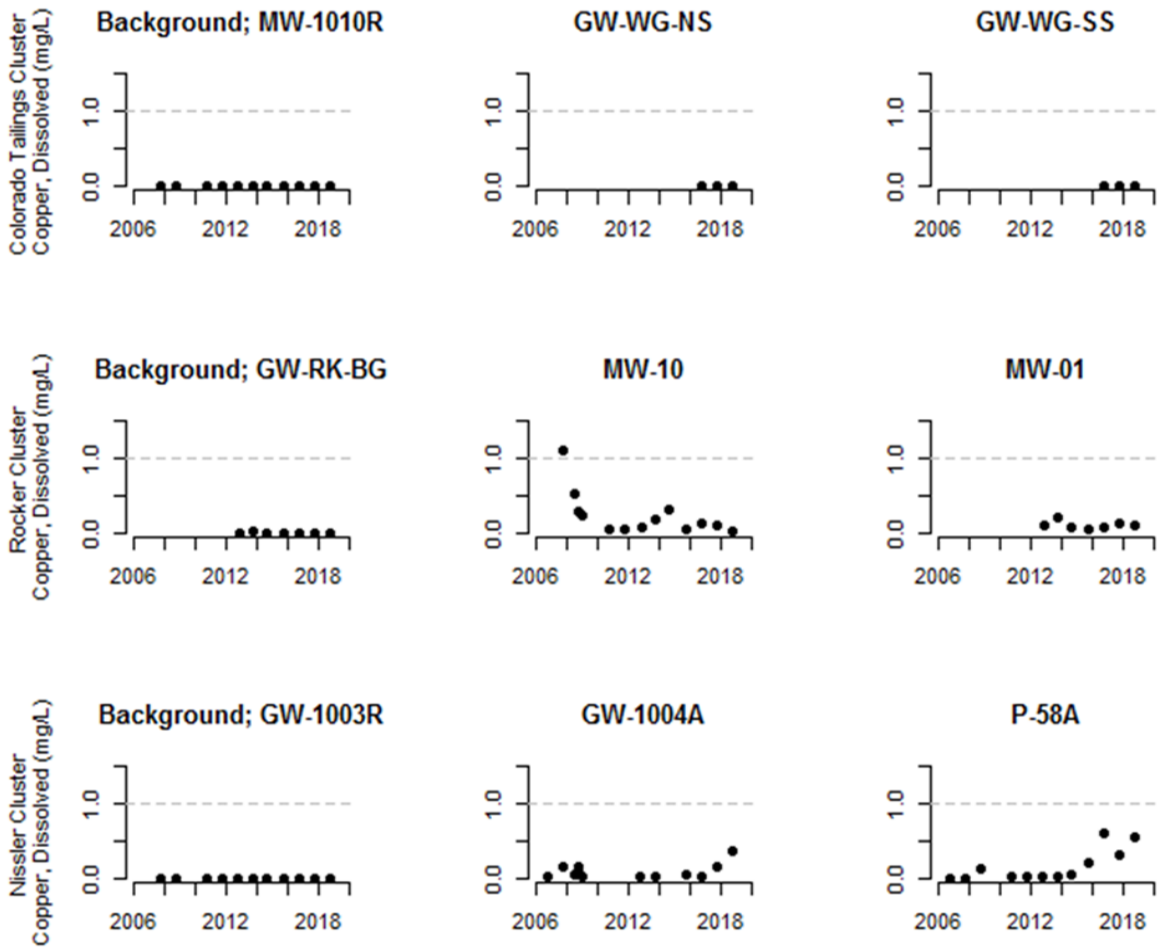

Figure 3-14. Copper concentrations in groundwater wells located in Subarea 1 of the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [MDHES, 1994]. Each row of plots represents a well cluster: Colorado Tailings Cluster, Rocker Cluster, and Nissler Cluster.

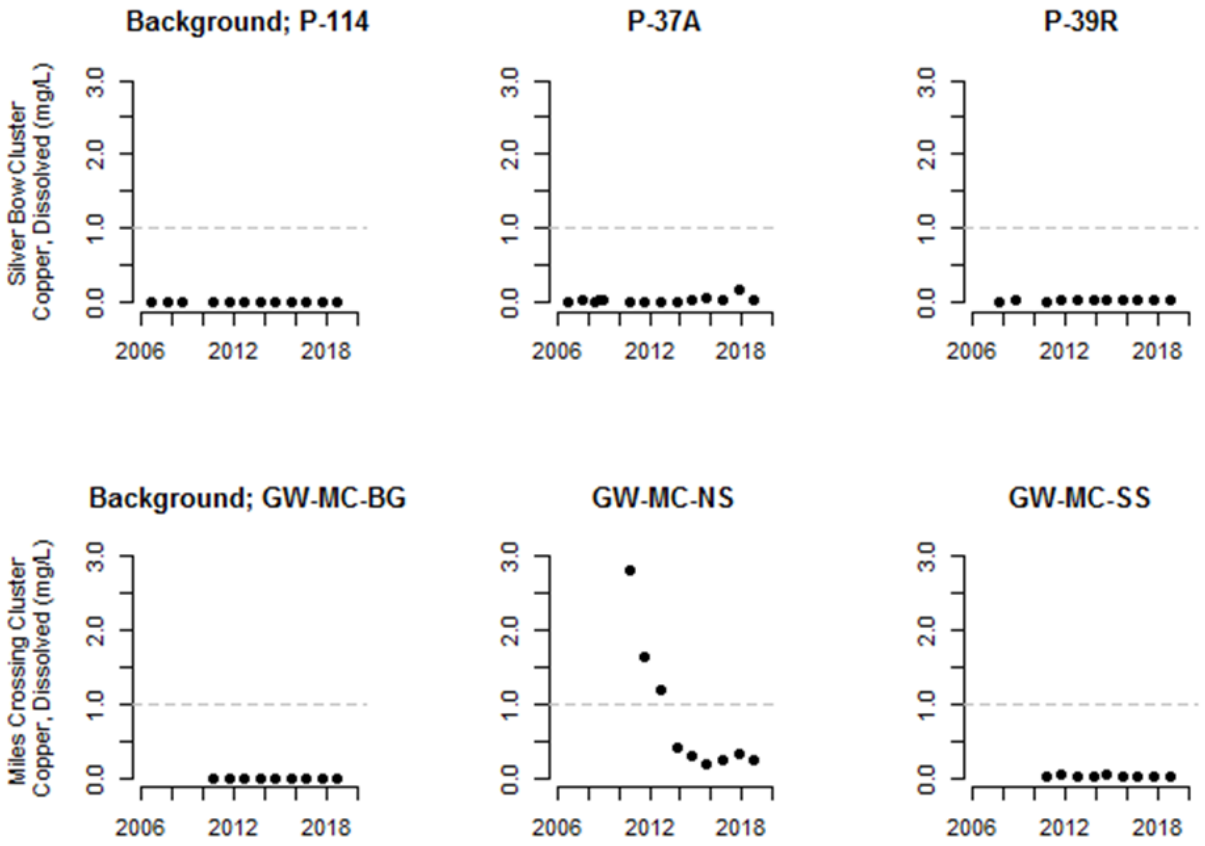

Figure 3-15. Copper concentrations in groundwater wells located in Subarea 2 of the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [MDHES, 1994]. Each row of plots represents a well cluster: Silver Bow Cluster and Miles Crossing Cluster.

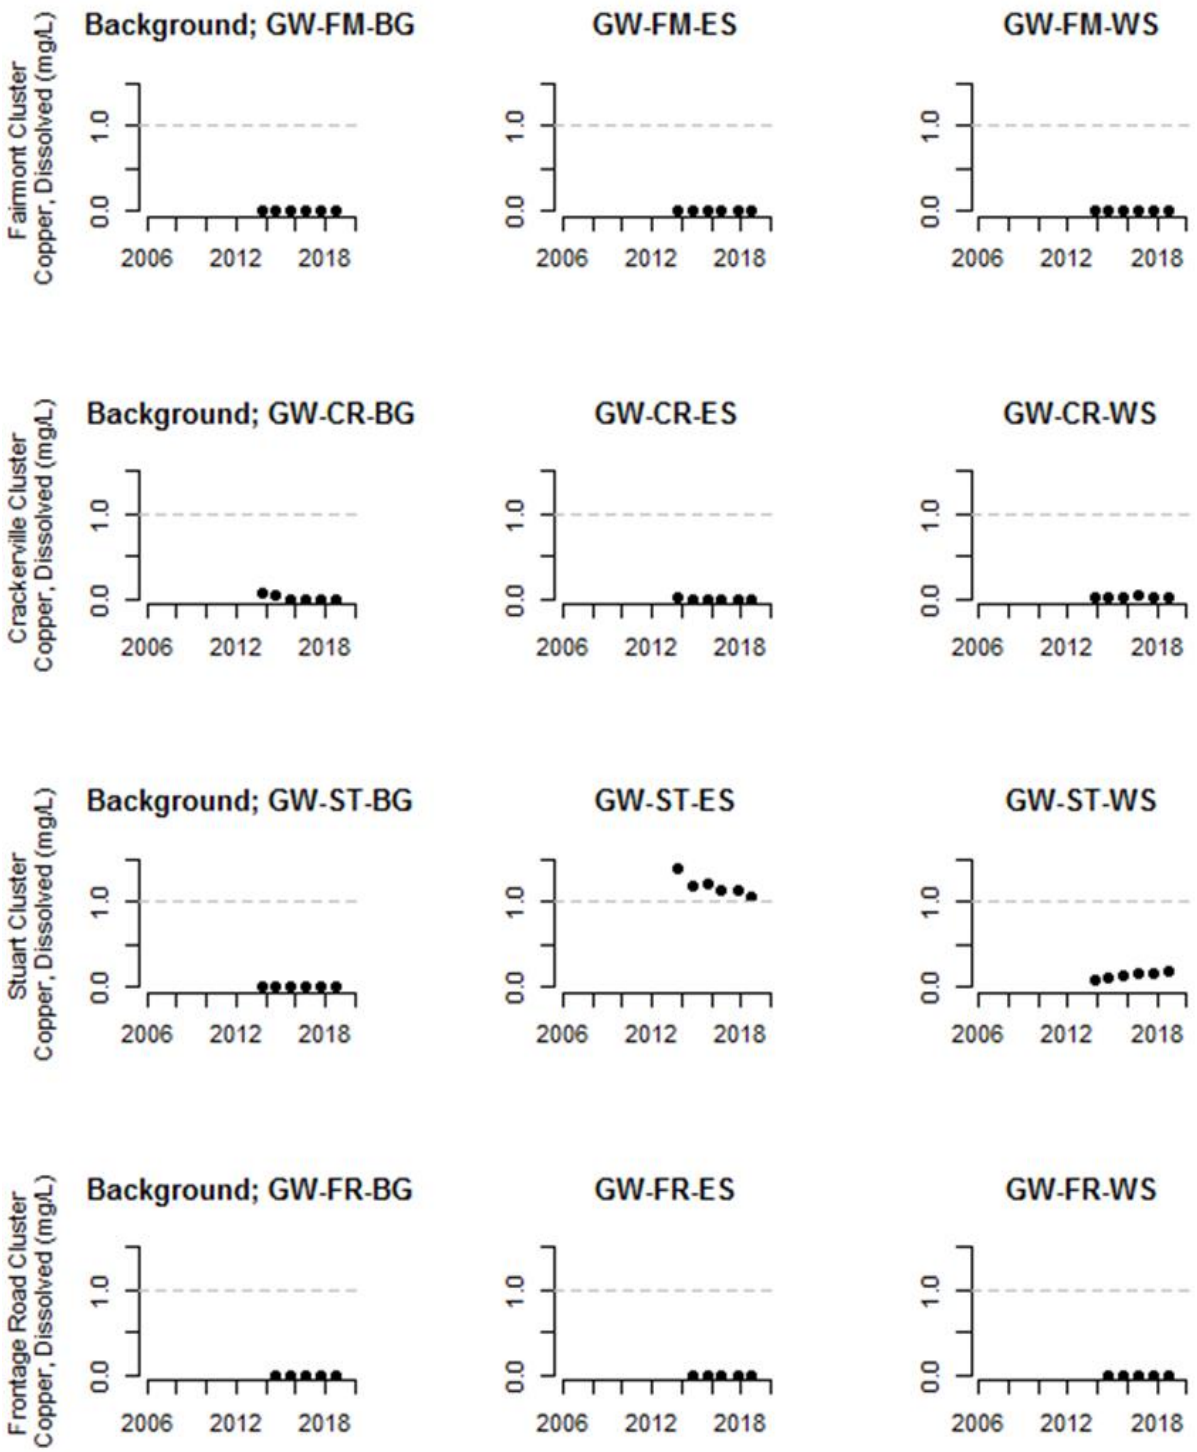

Figure 3-16. Copper concentrations in groundwater wells located in Subarea 4 of the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [MDHES, 1994]. Each row of plots represents a well cluster: Fairmont Cluster, Crackerville Cluster, Stuart Cluster, and Frontage Road Cluster.

3.4.2.1.4 Lead

Based on the monitoring period of record in the Silver Bow Creek floodplain, lead concentrations in floodplain monitoring wells have generally been similar to the concentrations in the background wells in Subarea 1 with a few exceptions (Figure 3-17). In the Nissler Cluster, Well GW-1004A has had relatively high (and variable) concentrations since 2014 (Figure 3-17). In the Rocker cluster, Well MW-10 had elevated lead concentrations in 2006–2007, but concentrations have subsided since 2008 (Figure 3-17). In Subarea 2, lead concentrations in the monitoring well have been similar to the background wells (Figure 3-18). In Subarea 4, lead concentrations in the monitoring wells were similar to, or lower than, the concentrations in the background wells in all clusters in 2014 and 2015 (Figure 3-19). However, lead concentrations in the Fairmont Cluster (Wells GW-FM-ES and GW-FM-WS) were substantially higher than the background well in 2013 (Figure 3-19).

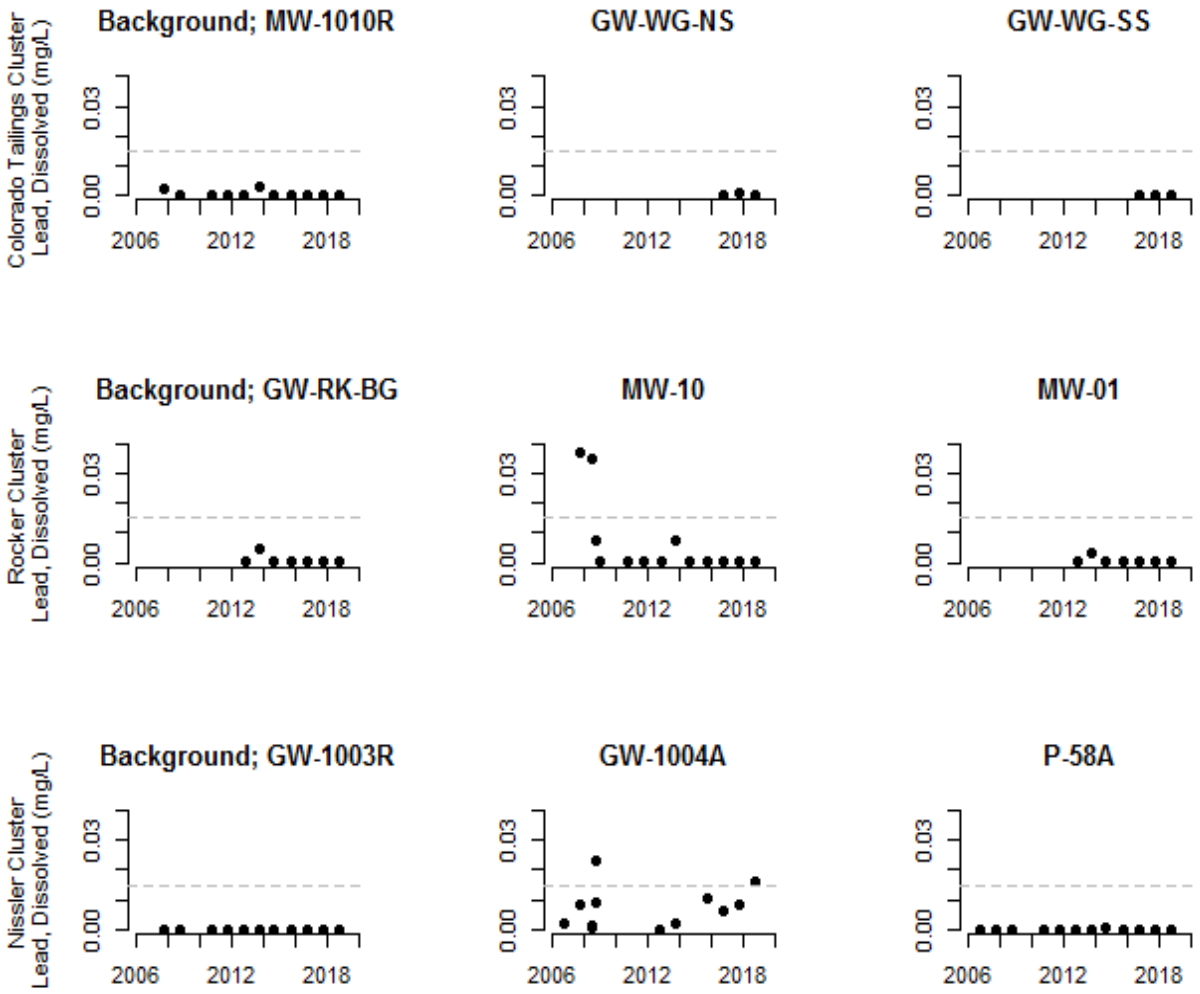

Figure 3-17. Lead concentrations in groundwater wells located in Subarea 1 of the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [DEQ, 2017]. Each row of plots represents a well cluster: Colorado Tailings Cluster, Rocker Cluster, and Nissler Cluster.

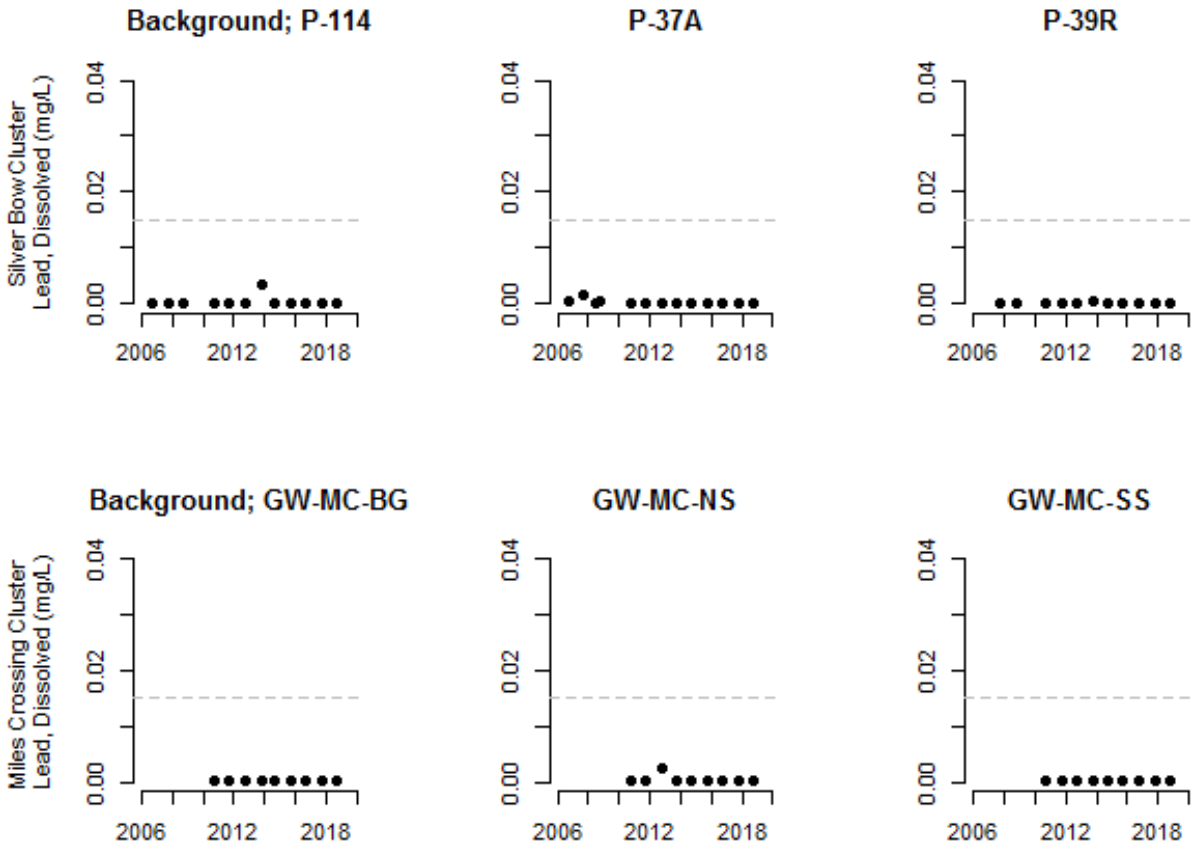

Figure 3-18. Lead concentrations in groundwater wells located in Subarea 2 of the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [DEQ, 2017]. Each row of plots represents a well cluster: Silver Bow Cluster and Miles Crossing Cluster.

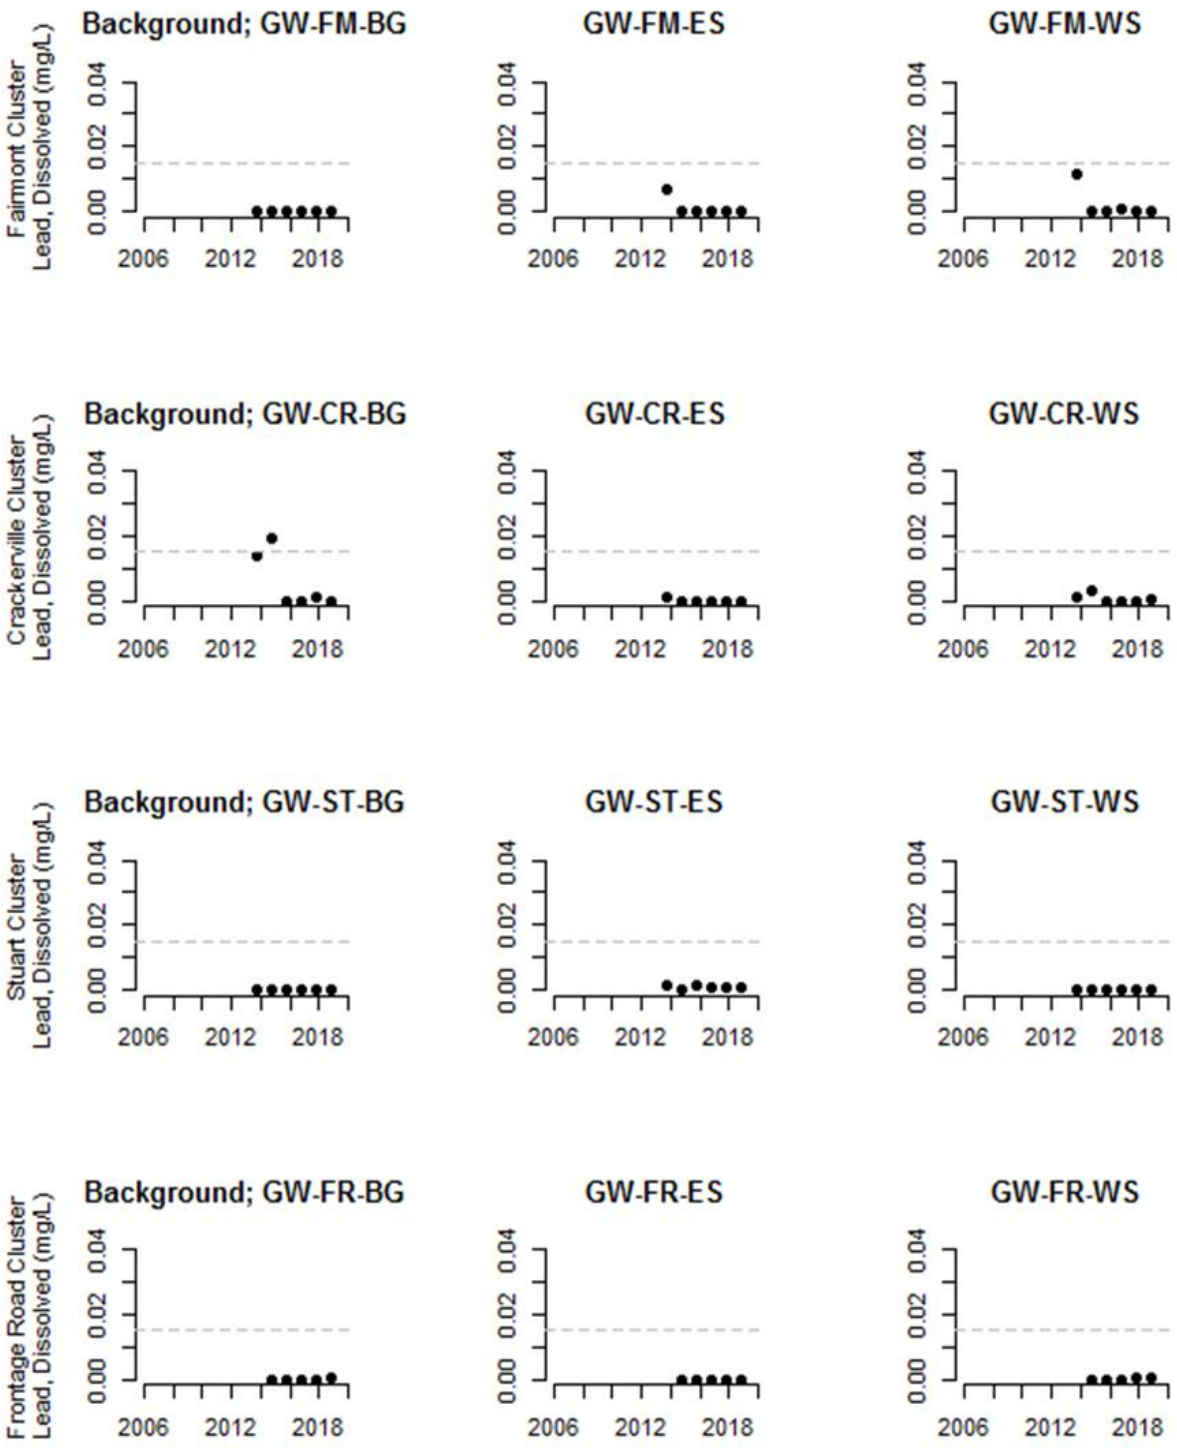

Figure 3-19. Lead concentrations in groundwater wells located in Subarea 4 of the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [DEQ, 2017]. Each row of plots represents a well cluster: Fairmont Cluster, Crackerville Cluster, Stuart Cluster, and Frontage Road Cluster.

3.4.2.1.5 Mercury

Based on the monitoring period of record in the Silver Bow Creek floodplain, mercury concentrations in the background wells have been similar to or less than the concentrations in the monitoring wells in all sample periods, except for one sample at Well GW-CR-WS in 2014 (Figure 3-20; Figure 3-21;Figure 3-22).

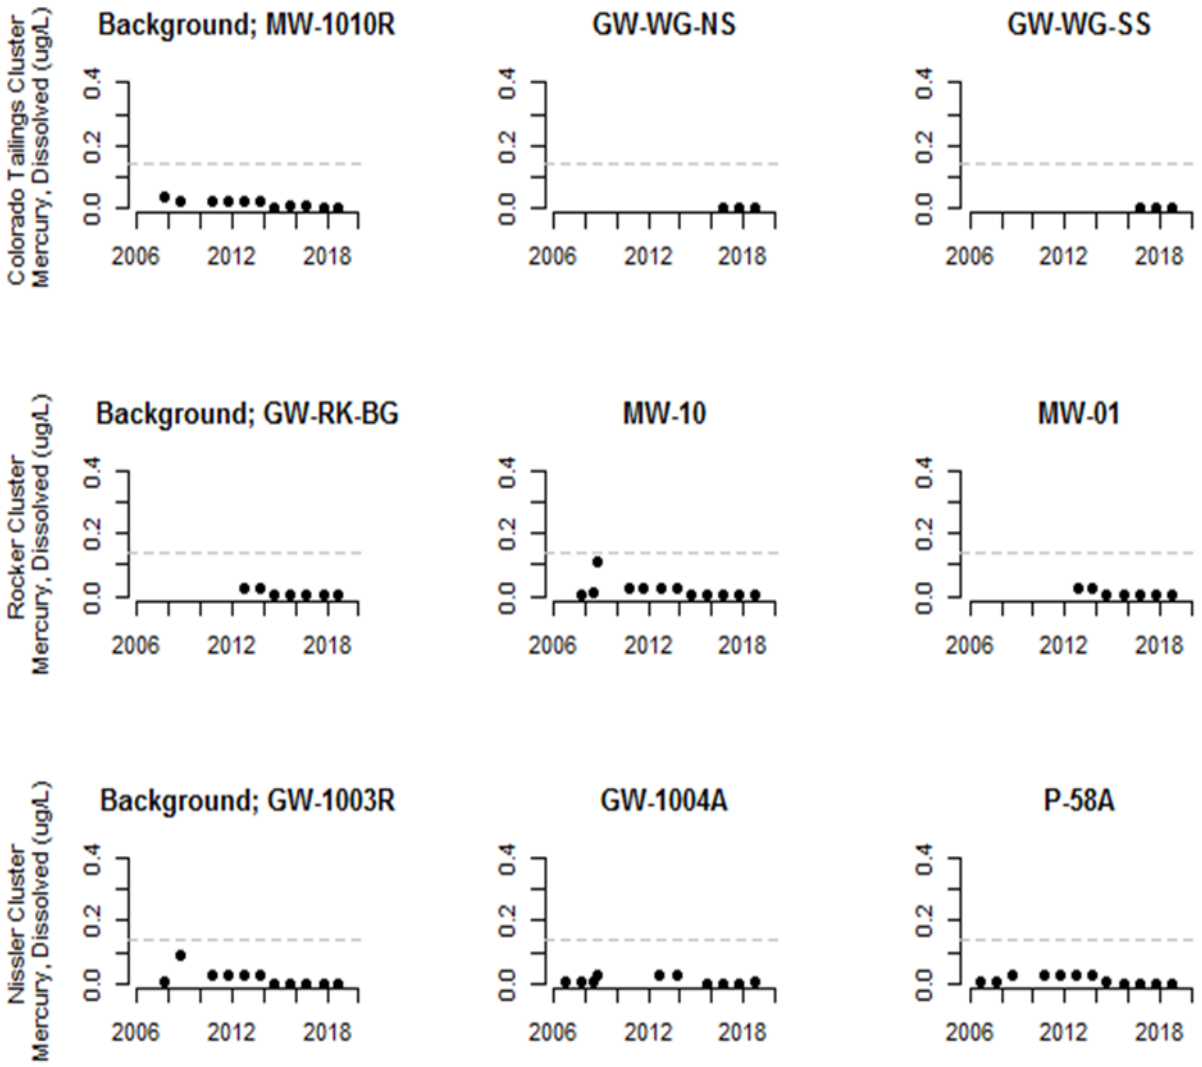

Figure 3-20. Mercury concentrations in groundwater wells located in Subarea 1 of the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [DEQ, 2017]. Each row of plots represents a well cluster: Colorado Tailings Cluster, Rocker Cluster, and Nissler Cluster.

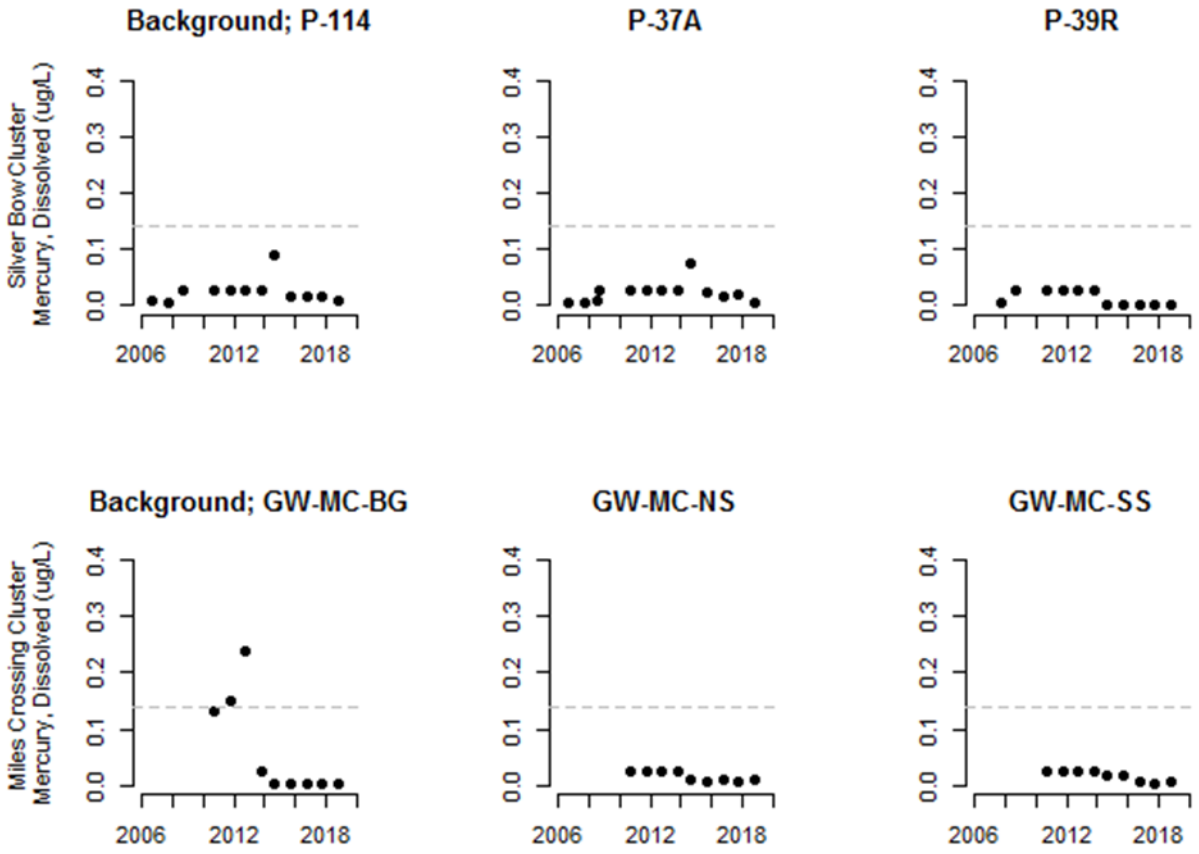

Figure 3-21. Mercury concentrations in groundwater wells located in Subarea 2 of the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [DEQ, 2017]. Each row of plots represents a well cluster: Silver Bow Cluster and Miles Crossing Cluster Colorado Tailings Cluster, Rocker Cluster, and Nissler Cluster.

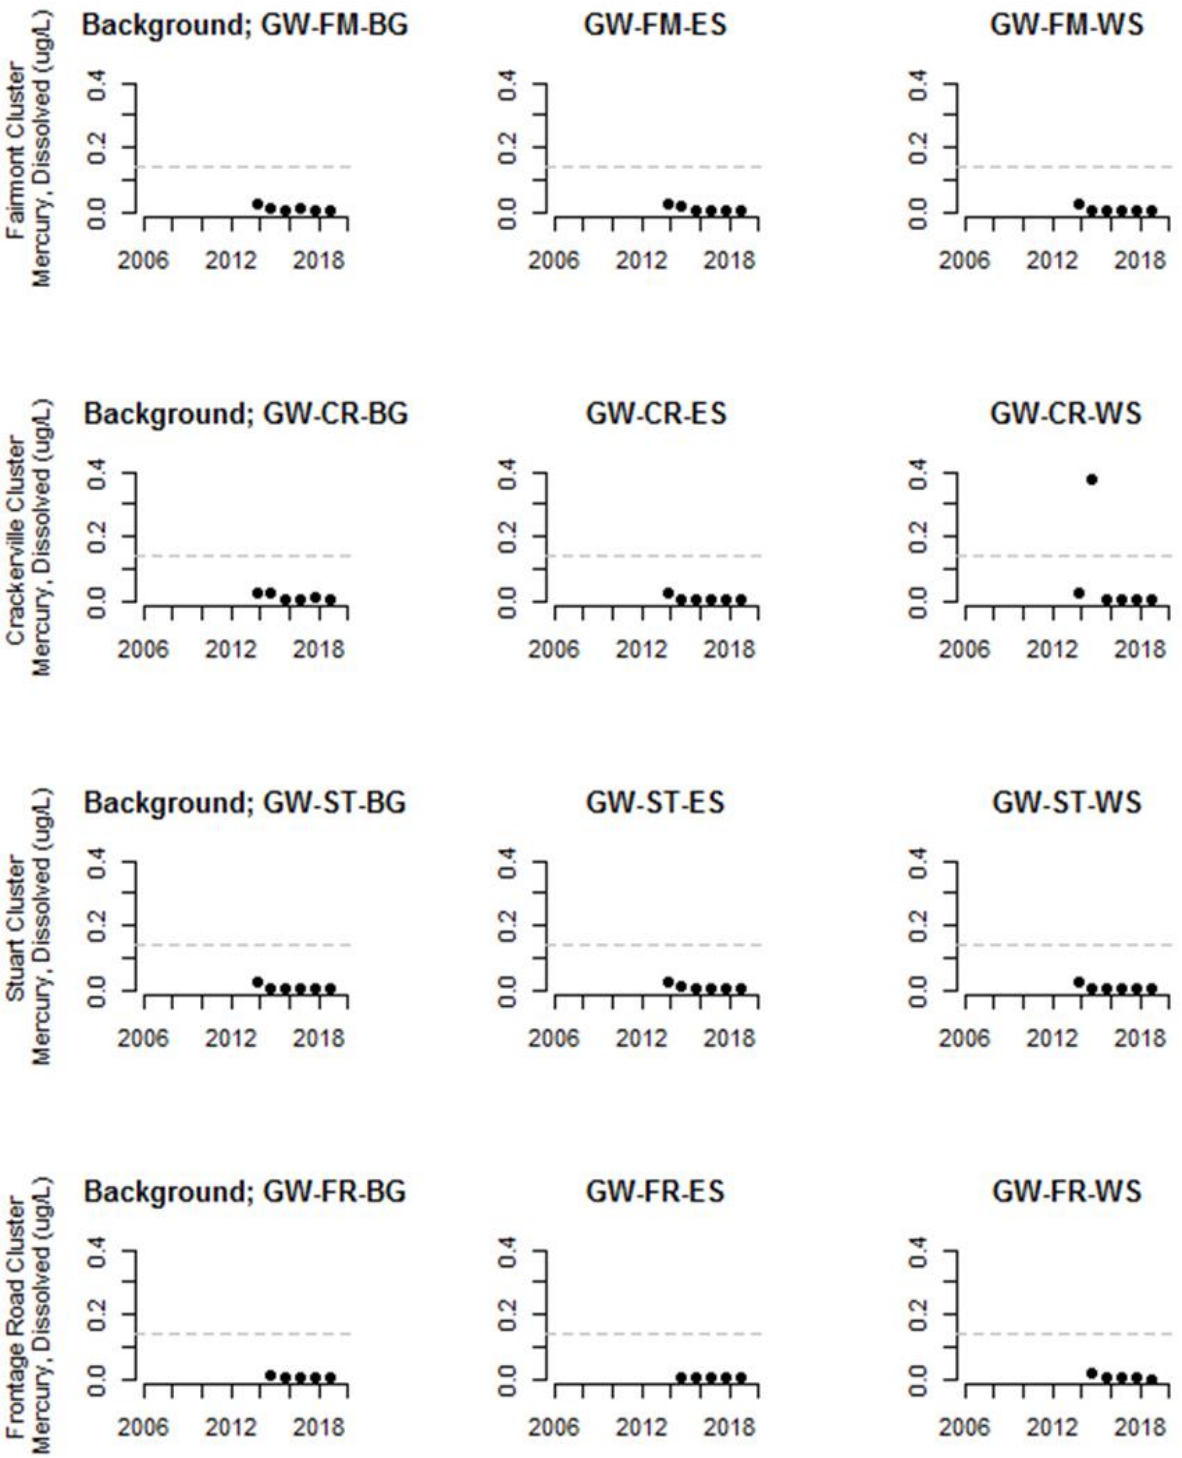

Figure 3-22. Mercury concentrations in groundwater wells located in Subarea 4 of the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [DEQ, 2017]. Each row of plots represents a well cluster: Fairmont Cluster, Crackerville Cluster, Stuart Cluster, and Frontage Road Cluster.

3.4.2.1.6 Zinc

Based on the monitoring period of record in the Silver Bow Creek floodplain, zinc concentrations in monitoring wells in the Rocker and Nissler Clusters (Subarea 1) (Figure 3-23), the Miles Crossing Cluster (Subarea 2) (Figure 3-24), and the Stuart Cluster (Subarea 4) (Figure 3-25) showed higher concentrations than the background wells. Monitoring well zinc concentrations that have routinely exceeded the groundwater standard [DEQ, 2017] include: Well MW-10 (Rocker Cluster) and Well GW-1004A and Well P-58A (Nissler Cluster) in Subarea 1 (Figure 3-23); Wells GW-MC-NS and GW-MC-SS (Miles Crossing Cluster) in Subarea 2 (Fiugre 3-24); and Wells GW-ST-ES and GW-ST-WS (Stuart Cluster) in Subarea 4 (Fiugre 3-25).

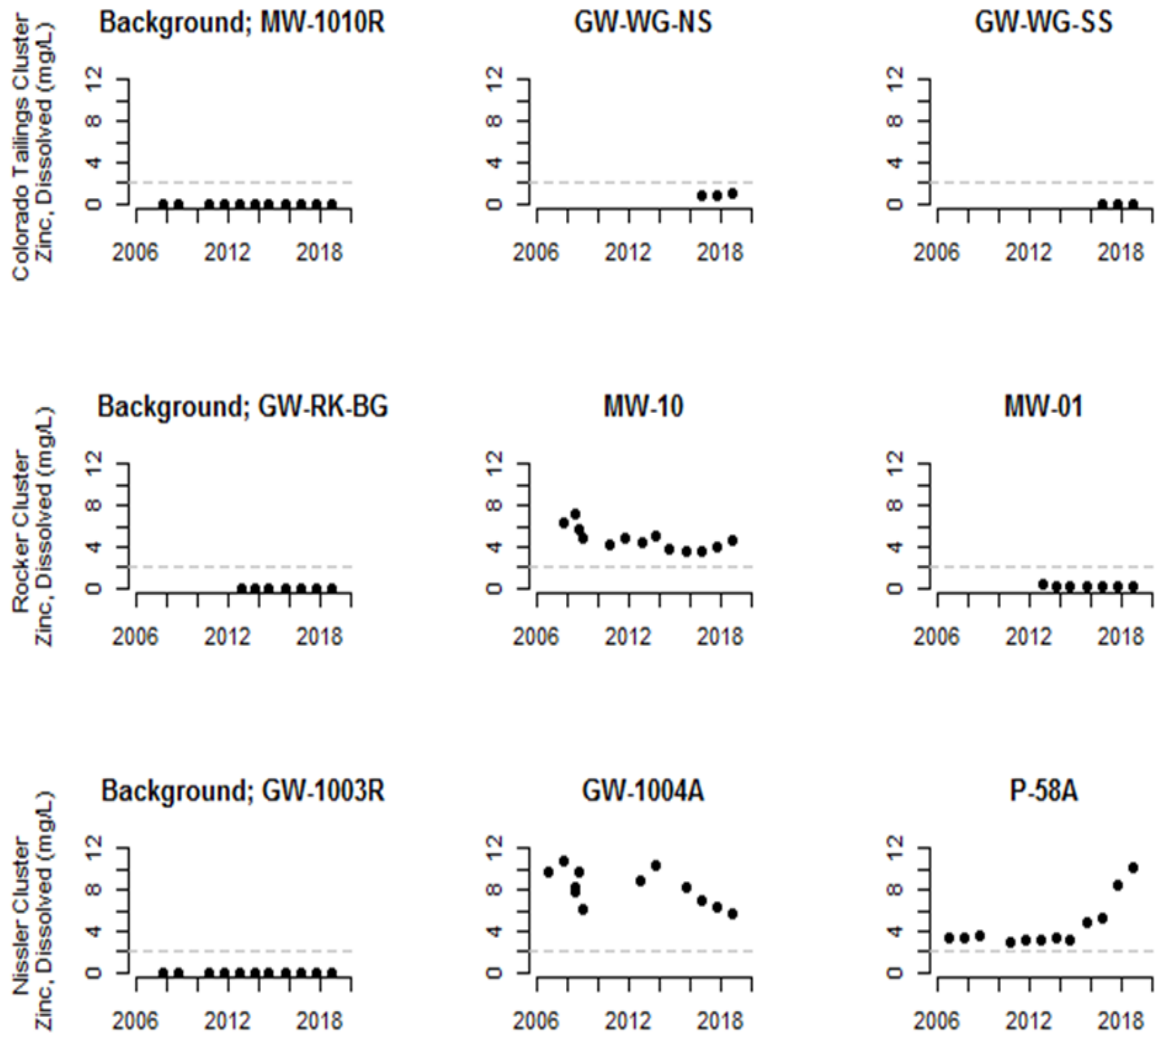

Figure 3-23. Zinc concentrations in groundwater wells located in Subarea 1 of the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [DEQ, 2017]. Each row of plots represents a well cluster: Colorado Tailings Cluster, Rocker Cluster, and Nissler Cluster.

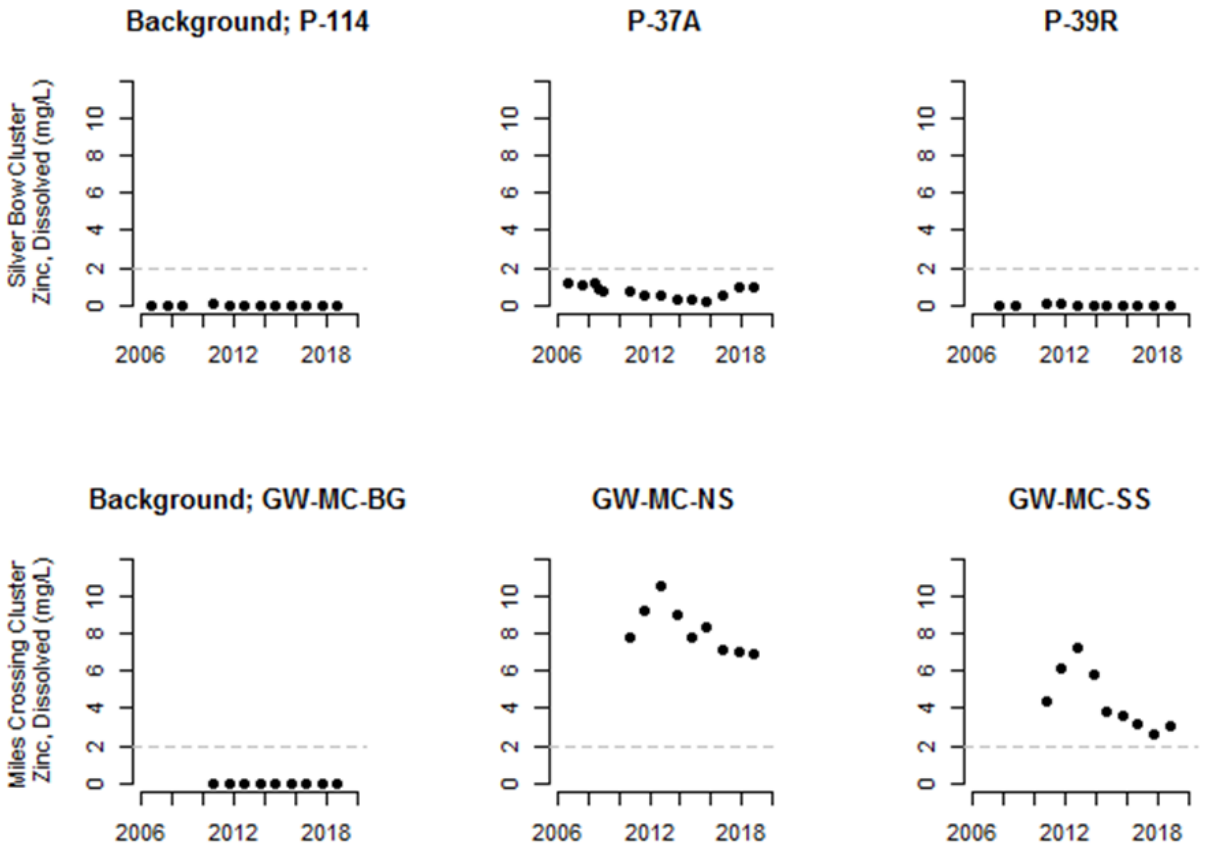

Figure 3-24. Zinc concentrations in groundwater wells located in Subarea 2 of the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [DEQ, 2017]. Each row of plots represents a well cluster: Silver Bow Cluster and Miles Crossing Cluster.

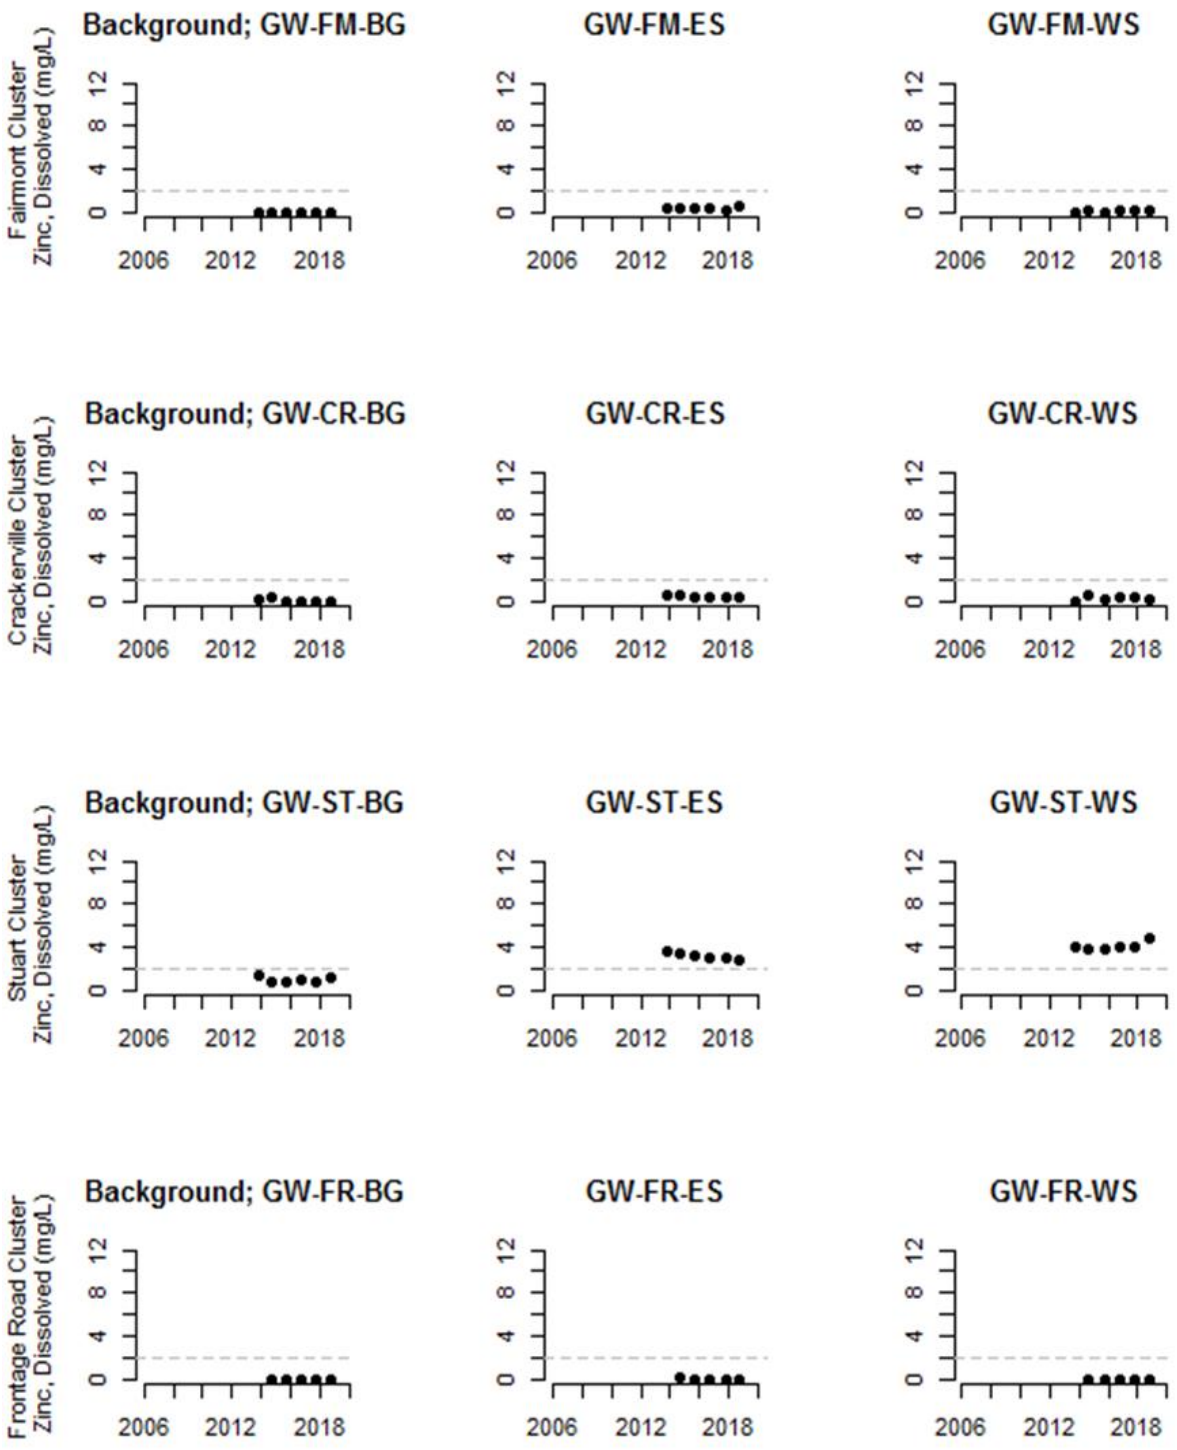

Figure 3-25. Zinc concentrations in groundwater wells located in Subarea 4 of the Streamside Tailings Operable Unit (2006–2018). Gray dashed line represents the human health groundwater standard [DEQ, 2017]. Each row of plots represents a well cluster: Fairmont Cluster, Crackerville Cluster, Stuart Cluster, and Frontage Road Cluster.

3.4.2.2 Other Metals

Concentrations of non-COC metals in the Silver Bow Creek floodplain wells in 2018 are displayed in Table 3-11. One monitoring well in the Colorado Tailings Cluster (Subarea 1) had an antimony concentration that exceeded the DEQ [2017] human health groundwater standard. Two samples had uranium concentrations that exceeded the DEQ [2017] human health groundwater standard: the background well MW-1010R in the Colorado Tailings Cluster and the monitoring well P-39R in the Silver Bow Cluster in Subarea 1 (Table 3-11).

3.4.2.3 Common Ions

Common ion concentrations in floodplain monitoring wells are depicted in Table 3-12. Calcium concentrations of most wells typically increased from 2017 to 2018.

3.4.3 Data Validation

Four field-blank samples were collected in 2018 and each was analyzed for 30 analytes. All analyte concentrations in all field blanks were below the analytical reporting limits.

Four field-duplicate samples were collected in 2018 and each analyte concentration in those samples was compared to the analyte concentration in the paired field sample. The relative percent difference (RPD) between each analyte pair (30 analytes per sample) was calculated for a total of 120 sample pairs. Of those 120 pairs, 5 pairs had at least one sample concentration that was more than 5 times the analytical reporting limit and had an RPD that was greater than 25 percent: total alkalinity, dissolved aluminum, bicarbonate, dissolved iron, and dissolved manganese in Well GW-FR-BG had RPDs of 28, 200, 29, 184, and 93 percent, respectively, on October 4, 2018.

A completed quality assurance and quality control checklist, summary tables of field-duplicate and field-blank results, and assessments of data quality objectives are included in Appendix A. Results from the analytical laboratory are included in Appendix B. The 2018 groundwater monitoring data are included in Appendix E.

3.5 DISCUSSION

3.5.1 Mine Waste Relocation Repository

Data from 2018 provided no evidence that COCs were leaching from the MWRR into nearby groundwater during wet (July) or dry periods (October). Except for arsenic, all COC concentrations in the monitoring wells were either below the analytical reporting limits or near the reporting limits. For arsenic, concentrations were consistently highest in the background monitoring well and these results are consistent with previous monitoring years. Data do not indicate that any substantial increases in COC concentrations are occurring through time in any of the MWRR monitoring wells, which would be expected if leaching of COC from the repository was occurring.

3.5.2 Floodplain

In 2018, several floodplain well samples had COC concentrations above the background well concentration, above the most restrictive MDHES [1994] or DEQ [2017] groundwater standard, or both. Arsenic concentrations were generally highest in the background wells, particularly in the Miles Crossing (Subarea 2) and Crackerville (Subarea 4) Clusters. However, cadmium, copper, lead, and zinc concentrations in certain monitoring wells were sometimes an order of magnitude higher than the concentration in the background well. Cadmium and zinc concentrations in monitoring wells were also frequently several times greater than the groundwater standard, and the copper and lead standards were each exceeded in one well. These results indicate that portions of the shallow groundwater aquifer in the SSTOU remain contaminated by COC. Uranium concentrations exceeded the DEQ [2017] groundwater standard in two wells, one of which was a background well. Monitoring results in 2018 were generally similar to previous years, although certain COC concentrations have been variable through time.

3.5.3 Data Validation

Quality assurance and quality control results suggested that field procedures in 2018 resulted in little or no sample contamination. All field blank analyte concentrations were below reporting limits suggesting decontamination procedures were adequate. All but two constituent comparisons of field samples and field duplicates were within the sampling precision data quality objectives for the project.

4.0 VADOSE ZONE WATER

4.1 INTRODUCTION

This chapter describes vadose zone water quality monitoring data collected in 2018 to evaluate the effectiveness of the Mine Waste Relocation Repository (MWRR) at isolating the vadose zone from metal contaminants of concern (COCs) in waste materials stored at the MWRR. If leaching of metal COCs from the MWRR occurs there is a potential for contamination of groundwater and surface water in the Streamside Tailings Operable Unit (SSTOU) of the Silver Bow Creek/Butte Area National Priorities List site.

The vadose zone is the area between the soil surface and the groundwater table. Vadose zone soil moisture can transport colloidal and dissolved nutrients, minerals, and contaminants through the soil column. Constituent concentrations are typically higher in vadose zone water compared to groundwater; therefore, existing groundwater standards are not applicable to vadose zone water. Instead of groundwater standard comparisons, COC concentrations in vadose zone water at lysimeters, which are located down-gradient from the repository (i.e., monitoring lysimeters) were evaluated and compared to COC concentrations from previous years to look for variation in concentrations over time. If COC concentrations are increasing over time, leaching of COCs from the repository may be in progress.

4.2 METHODS

The purpose of the vadose zone monitoring program is to collect data that describe temporal variation of metal and ion concentrations in vadose zone water near the MWRR in the SSTOU. These data provide a long-term record of vadose zone water COC and ion concentrations near the MWRR. These long-term data will be used to assess if leaching COCs from the MWRR to groundwater and surface water in the SSTOU has occurred or is occurring. A record of changes to the vadose zone monitoring program is provided in the program monitoring plan [RESPEC, 2018b]. This monitoring program attempts to fully adhere to monitoring requirements specified in the SSTOU Record of Decision (ROD) (Table 4-1).

4.2.1 Monitoring Locations

Vadose zone water chemistry was monitored at eight lysimeters located near the MWRR in 2018 (Figure 4-1). LYS-04 was discontinued due to malfunction and replaced with LYS-04R in 2018 (Figure 4-1;

Table 4-2).

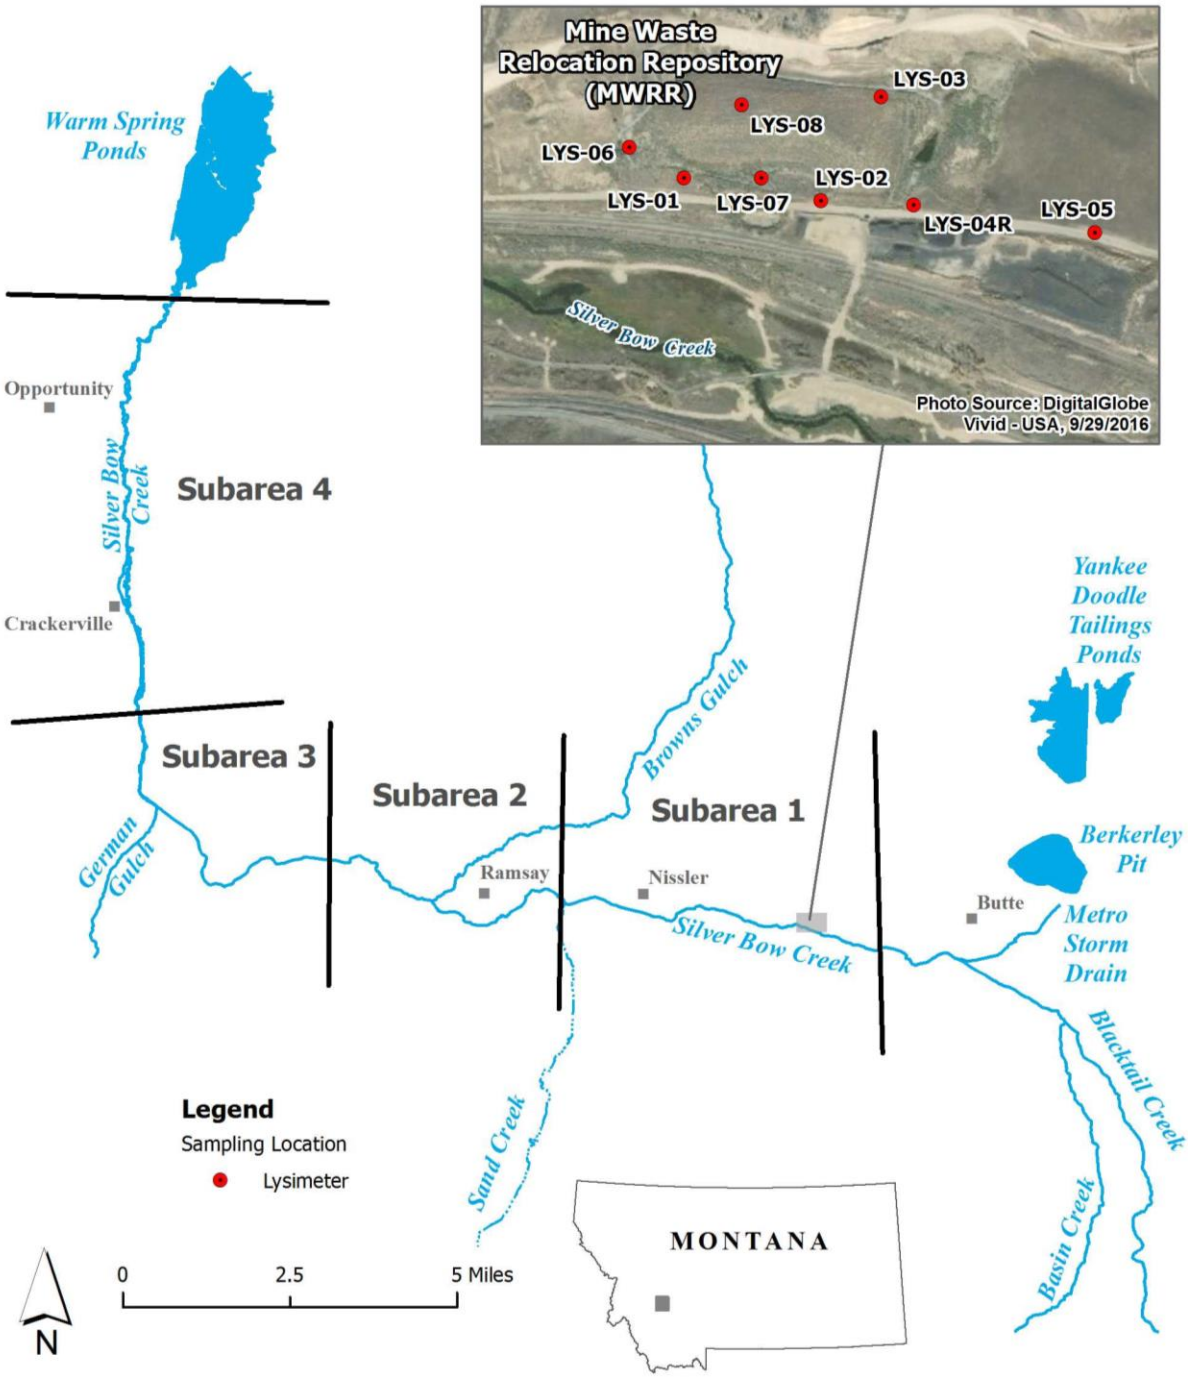

Figure 4-1. Sampling locations for vadose zone water monitoring in the Streamside Tailings Operable Unit.

Table 4-1. Minimum post-remedy monitoring requirements specified in the Record of Decision for the Streamside Tailings Operable Unit [DEQ and USEPA, 1995].

Locations/Physical	Analytical Parameters	Analytes
In conjunction with groundwater sampling locations; three (3) per repository location	Metals (dissolved)	Arsenic, cadmium, copper, lead, mercury, zinc
	Common ions	Calcium, magnesium, sodium, potassium, chloride, sulfate
	Physical properties	Temperature, acidity (pH), oxidation-reduction potential, conductance

Table 4-2. Lysimeter locations for vadose zone water monitoring of the Mine Waste Relocation Repository in the Streamside Tailings Operable Unit.

Lysimeter ID	Purpose	Location (GPS coordinates, NAD 83)	
		Latitude	Longitude
LYS-01	Monitoring	46.00261	–112.58599
LYS-02	Monitoring	46.00244	–112.58403
LYS-03	Monitoring	46.00349	–112.58323
LYS-04R	Monitoring	46.00243	-112.58270
LYS-05	Monitoring	46.00223	–112.58011
LYS-06	Background	46.00289	–112.58679
LYS-07	Monitoring	46.00264	–112.58489
LYS-08	Monitoring	46.00336	–112.58521

4.2.2 Monitoring Parameters

Vadose zone water samples were analyzed for the parameters and analytes listed in Table 4-3.

Table 4-3. Sampling parameters and analytes for vadose zone water monitoring near the Mine Waste Relocation Repository of the Streamside Tailings Operable Unit.

Parameter	Analytes
Concentrations of metal contaminants of concern (dissolved)	Arsenic, cadmium, copper, lead, mercury, zinc
Concentrations of other metals (dissolved)	Aluminum, antimony, barium, beryllium, boron, cobalt, chromium, iron, manganese, molybdenum, nickel, selenium, silver, uranium, vanadium
Common ion concentrations	Sulfate, total alkalinity, bicarbonate alkalinity, calcium, magnesium, sodium, potassium, chloride, hardness

4.2.3 Sample Collection and Analysis Procedures

Sample collection, analysis, and quality assurance procedures are described in the project sampling and analysis plan [RESPEC, 2018b]. The methods generally followed standard operating procedures (SOPs) developed for the Clark Fork River [AR, 1992]. Field sampling procedures were in accordance with DEQ [2012a] and followed the "clean hands/dirty hands" procedures described in the US Geological Survey [2006].

Because of low sample volumes in the lysimeters, some deviations from the described SOPs occurred. Sample bottles were not triple rinsed with each sample before collection, and samples were lab filtered, instead of being field filtered. When sample volume was very limited (less than 20 milliliters [mL]), dissolved metals were prioritized over common ions for laboratory analysis. Finally, field parameters (i.e., water temperature, pH, dissolved oxygen concentration, and conductivity) were not measured.

Calibration methods for field meters, data recording and handling methods, and quality assurance and quality control procedures are described in the project quality assurance project plan (QAPP) [RESPEC, 2014]. Samples were analyzed by Energy Laboratories (Helena, Montana). Laboratory analysis procedures for each analyte are presented in Table 4-4.

4.2.4 Data Analysis

Dissolved metal and common ion concentrations from 2018 are tabulated for each sampling event in each monitoring lysimeter. In addition, all metal COC concentrations are plotted through time for the monitoring period from 2010–2018 for assessing temporal trends at each site.

4.2.5 Data Validation

Data quality objectives were established in the SSTOU monitoring project quality assurance project plan (QAPP) for data representativeness, comparability, completeness, sensitivity, precision, bias, and accuracy [RESPEC, 2014]. Methods for field and laboratory procedures are described in detail in the project QAPP. A completed quality assurance and quality control

checklist, summary tables of field duplicate and field blank results, and assessments of data quality objectives are included in Appendix A.

Table 4-4. Analytes, methods, and reporting limits for groundwater sampling in the Streamside Tailings Operable Unit.

Analyte	Requested Method	Requested Reporting Limit (mg/L)[50]	Holding Time (days)	Bottle	Preservative[51]
Water Samples - Physical Properties and Inorganics					
Alkalinity, Total (as $CaCO_3$)	A 2320 B	4	14	500 mL HDPE	4 ± 2 C
Alkalinity, Bicarbonate (as HCO_3)	A 2320 B	4	14		
Chloride	EPA 300.0	1	28		
Sulfate	EPA 300.0	1	28		
Hardness (as $CaCO_3$)	A 2340 B	1	180		
Water Samples - Dissolved Metals (0.45 µm filtered)[(b)]					
Aluminum	EPA 200.8	0.009	180	250 mL HDPE	HNO_3 to pH <2
Antimony	EPA 200.8	0.0005			
Arsenic	EPA 200.8	0.001			
Barium	EPA 200.8	0.003			
Beryllium	EPA 200.8	0.0008			
Boron	EPA 200.7	0.1			
Cadmium	EPA 200.8	0.00003			
Calcium	EPA 200.8	1			
Chromium	EPA 200.8	0.01			
Cobalt	EPA 200.8	0.01			
Copper	EPA 200.8	0.001			
Iron	EPA 200.8	0.02			
Lead	EPA 200.8	0.0003			
Magnesium	EPA 200.7	1			
Manganese	EPA 200.8	0.001			
Molybdenum	EPA 200.8	0.005			
Nickel	EPA 200.8	0.002			
Potassium	EPA 200.7	1			
Selenium	EPA 200.8	0.001			
Silver	EPA 200.8	0.0002			
Sodium	EPA 200.7	1			

[50] Requested reporting limits are either the required reporting limit from DEQ [2017], DEQ [2014] (for nutrients), or the lowest reporting limit previously provided by the analytical laboratory, whichever is lower.

[51] Vadose zone water samples were laboratory filtered.

Analyte	Requested Method	Requested Reporting Limit (mg/L)[50]	Holding Time (days)	Bottle	Preservative[51]
Uranium	EPA 200.8	0.0002			
Vanadium	EPA 200.8	0.1			
Zinc	EPA 200.8	0.008			
Mercury	EPA 245.1	0.000005	28		

4.3 PERFORMANCE GOALS

Specific numeric concentration cleanup goals do not exist for vadose zone water COC concentrations in the SSTOU ROD [DEQ and USEPA, 1995]. The ROD specifies metal and common ion concentrations need to be monitored in vadose zone water at each waste repository to assess the mobility of contaminants from the repository sites to underlying groundwater or to the Silver Bow Creek floodplain down-gradient from any repositories. The MWRR is the only waste repository established in the SSTOU at this time.

4.4 RESULTS

Dissolved metal COC concentrations in MWRR lysimeters in 2018 are presented in Table 4-5. Concentrations of dissolved metals that are not COCs in MWRR lysimeters are presented in Table 4-6. Common ion concentrations in MWRR lysimeters are presented in **Table 4-7**.

In July 2018, sample volumes were sufficient for analyzing dissolved metals in all lysimeters (Table 4-5; Table 4-6) but sample volumes were insufficient to analyze all common ions in LYS-07 and LYS-08 (**Table 4-7**). In October 2018, sample volumes were sufficient for analysis of dissolved metals in all lysimeters (Table 4-5; Table 4-6), but insufficient for analysis of some common ions in LYS-03, LYS-04R, LYS-05, LYS-07, and LYS-08 (**Table 4-7**).

[52] Because of insufficient sample volumes during some sample periods, mercury was not analyzed in all samples at LYS-03, LYS-07, and LYS-08. The total number of mercury samples at those lysimeters were: LYS-03 (12 mercury samples), LYS-07 (14 mercury samples), and LYS-08 (11 mercury samples).

4.4.1 Arsenic

In 2018, arsenic concentrations in each MWRR lysimeter were generally similar to previous years, except for LYS-03 which was higher than in prior monitoring periods (0.231 mg/L) in October 2018 (Figure 4-2). Also, LYS-08 was high in July 2018 (0.117 mg/L) in July 2018 (Figure 4-2). Arsenic concentrations appear to be increasing over time at LYS-03 and decreasing over time at LYS-02 (Figure 4-2).

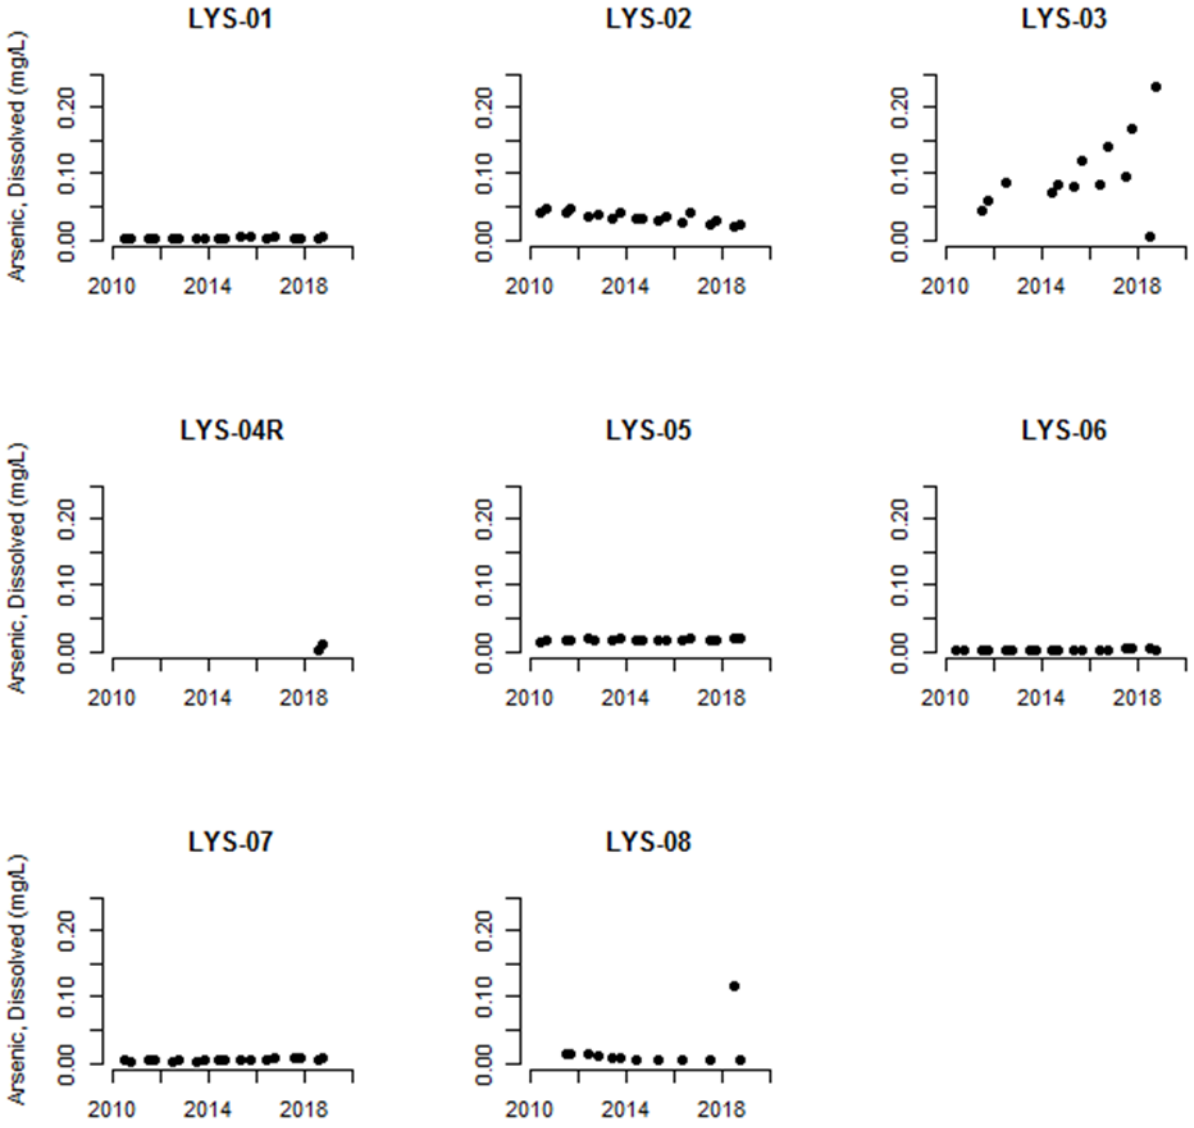

Figure 4-2. Arsenic concentrations in lysimeters of the Mine Waste Relocation Repository in the Streamside Tailings Operable Unit (2010–2018).

4.4.2 Cadmium

In 2018, cadmium concentrations in each MWRR lysimeter were similar to prior years (Figure 4-3). No lysimeters appeared to have increasing cadmium concentrations (Figure 4-3). Cadmium concentrations in LYS-05 appear to be decreasing over time (Figure 4-3).

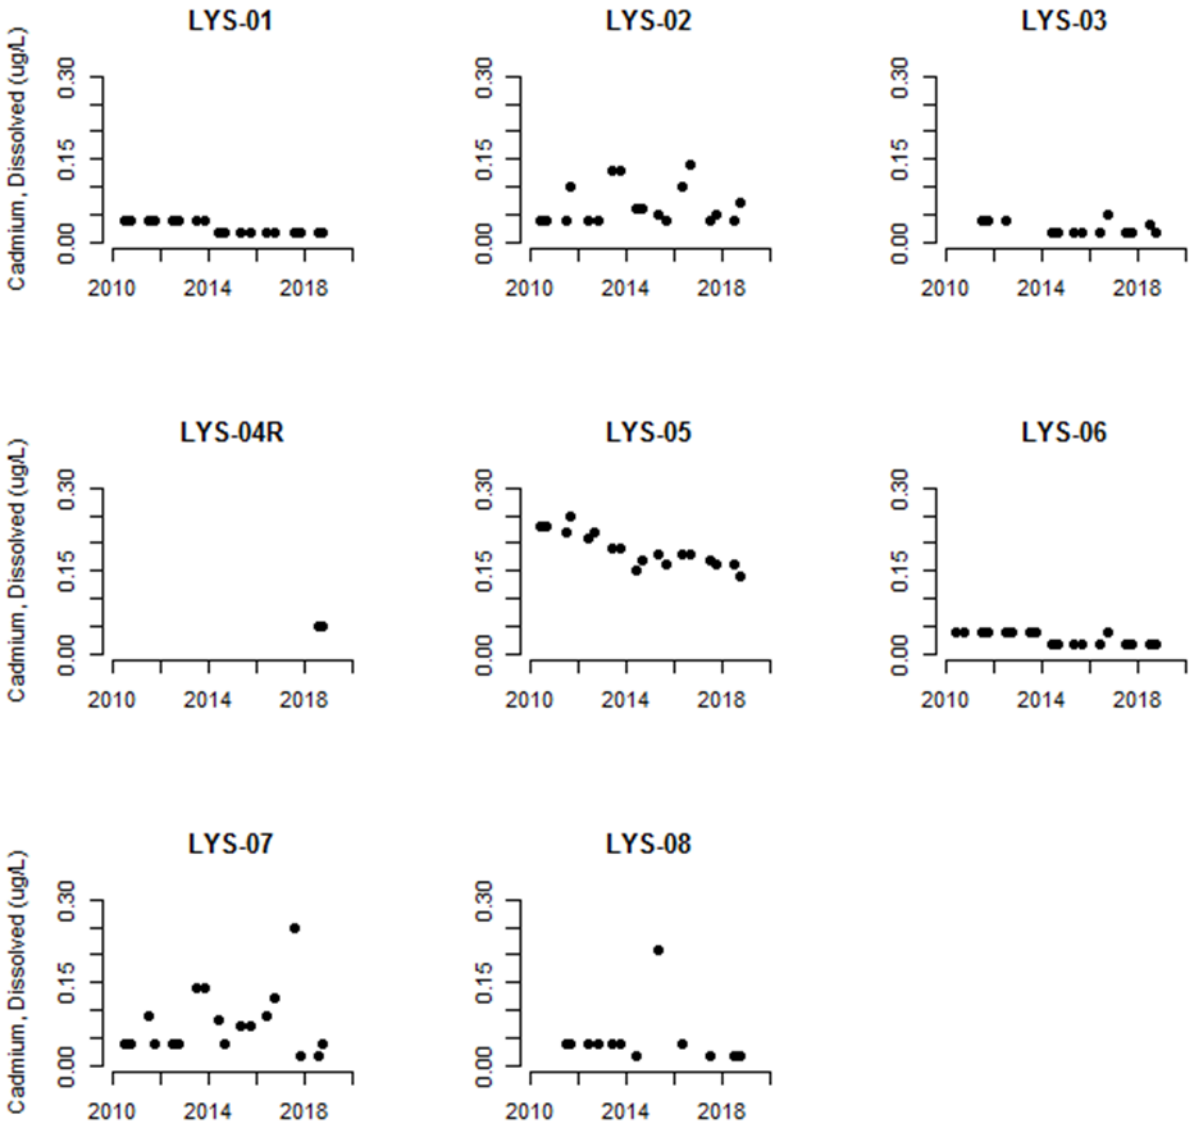

Figure 4-3. Cadmium concentrations in lysimeters of the Mine Waste Relocation Repository in the Streamside Tailings Operable Unit (2010–2018).

4.4.3 Copper

In 2018, copper concentrations in each MWRR lysimeter were similar to previous years (Fi9gure 4-4). Copper concentrations appear to be increasing over time in LYS-02 (Figure 4-4). No other lysimeter demonstrated any evidence of an increasing trend (Figure 4-4).

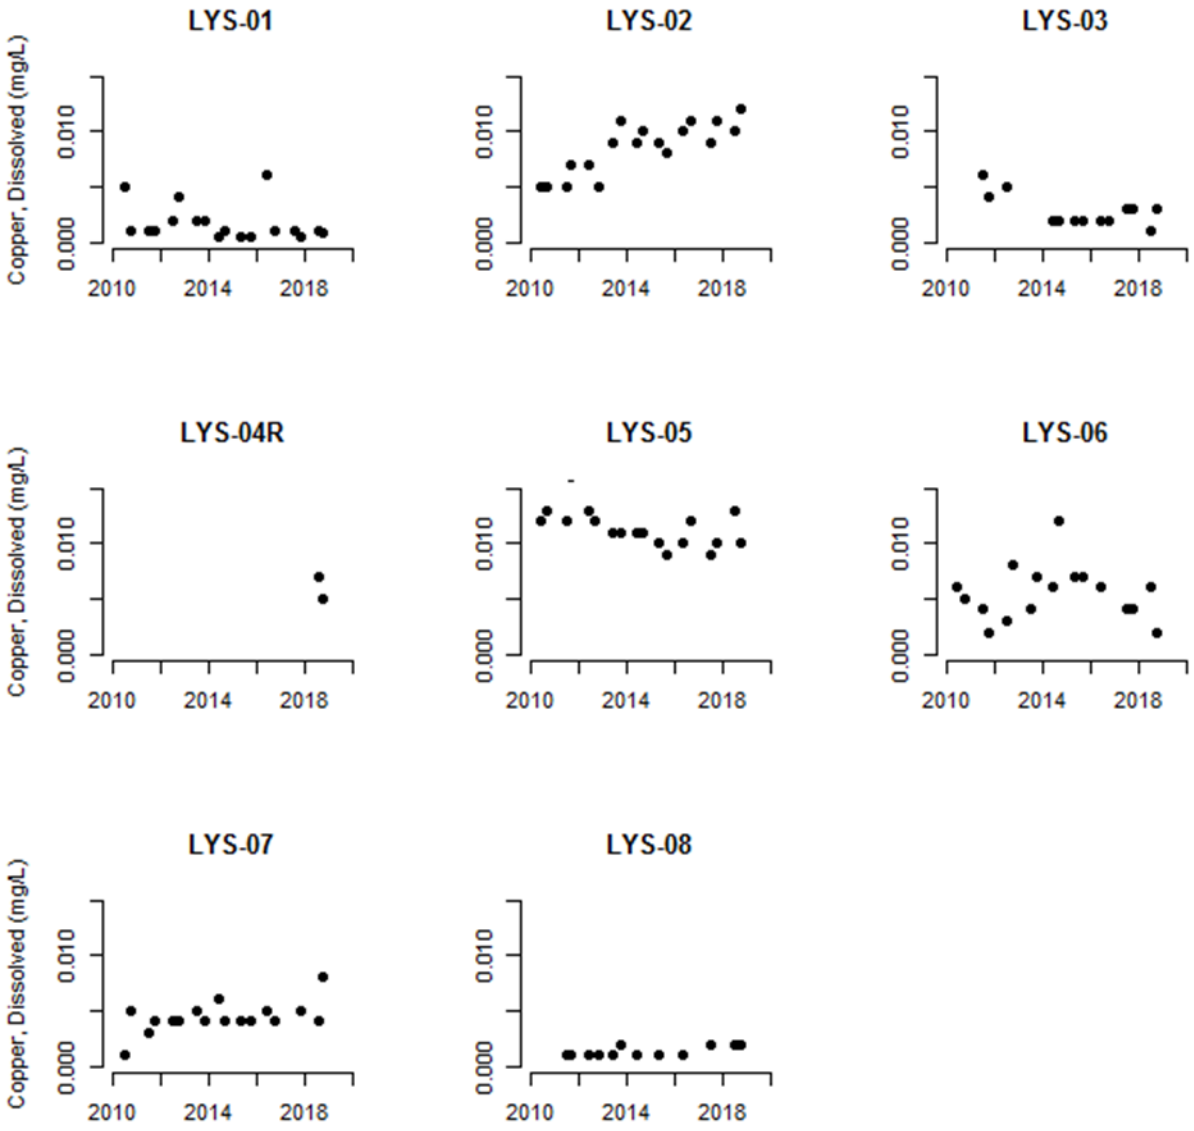

Figure 4-4. Copper concentrations in lysimeters of the Mine Waste Relocation Repository in the Streamside Tailings Operable Unit (2010–2018).

4.4.4 Lead

In 2018, lead concentrations in each MWRR lysimeter were similar to previous years (Figure 4-5). No lysimeters appeared to have increasing lead concentrations (Figure 4-5). All 2018 samples, except LYS-07 in October, had lead concentrations below the analytical reporting limit (Figure 4-5). Of the 117 samples collected in these lysimeters since 2010, 114 samples (97 percent) have had lead concentrations below analytical reporting limits (Figure 4-5).

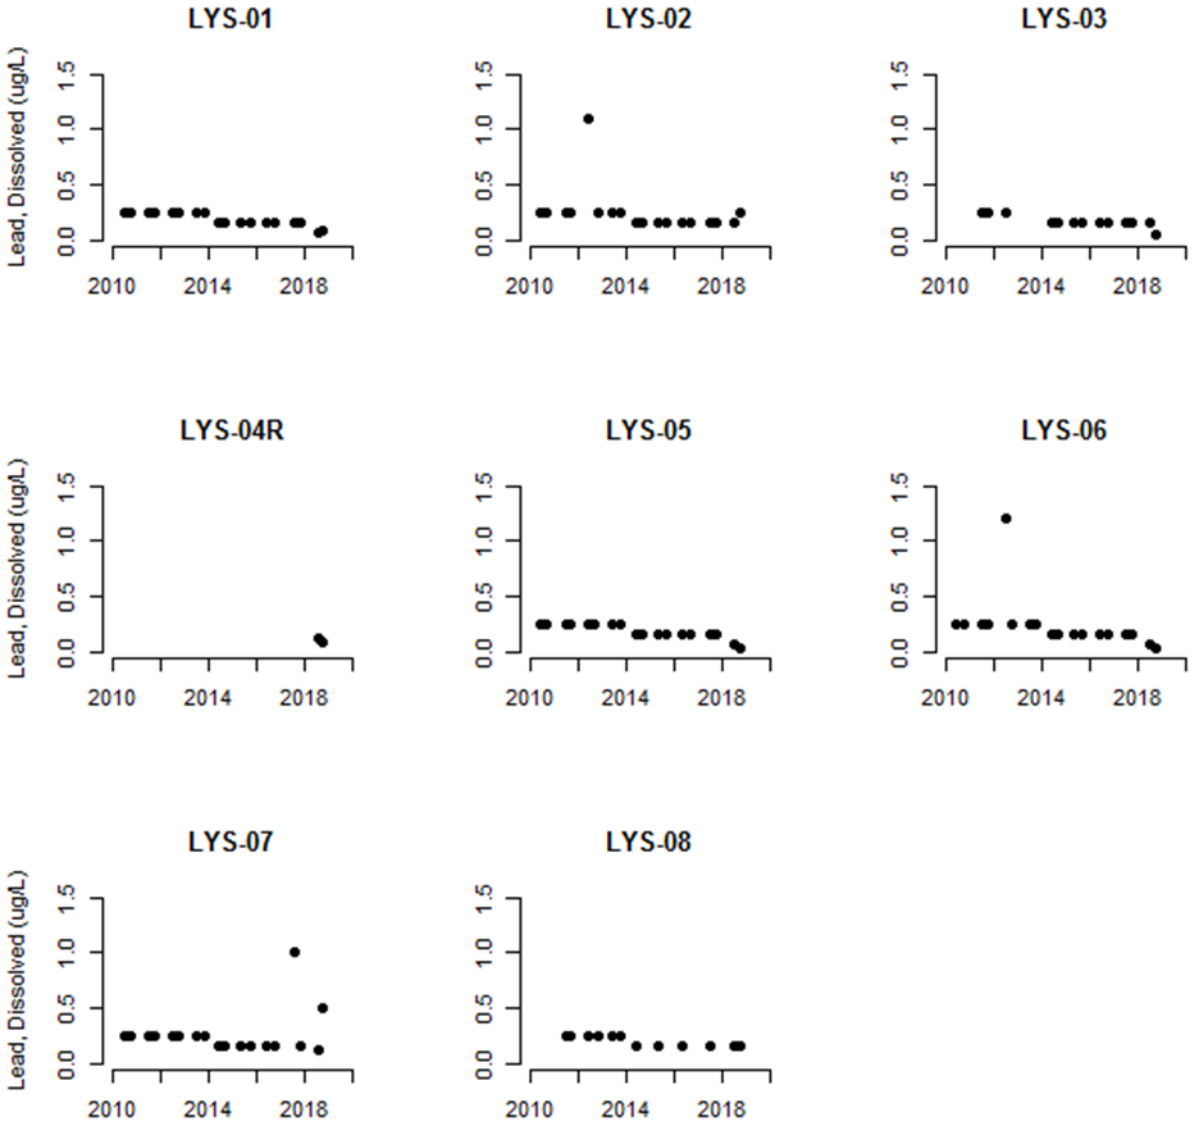

Figure 4-5. Lead concentrations in lysimeters of the Mine Waste Relocation Repository in the Streamside Tailings Operable Unit (2010–2018).

4.4.5 Mercury

In 2018, mercury concentrations in each MWRR lysimeter were similar to previous years (Figure 4-6). No lysimeters appeared to have increasing mercury concentrations over time (Figure 4-6). Except for two samples (LYS-02 and LYS-05 in October), all of the 2018 samples had mercury concentrations below the analytical reporting limit (Figure 4-6). Of the 111 samples collected in these lysimeters since 2010, 89 samples (80 percent) have had mercury concentrations below analytical reporting limits (Figure 4-6).

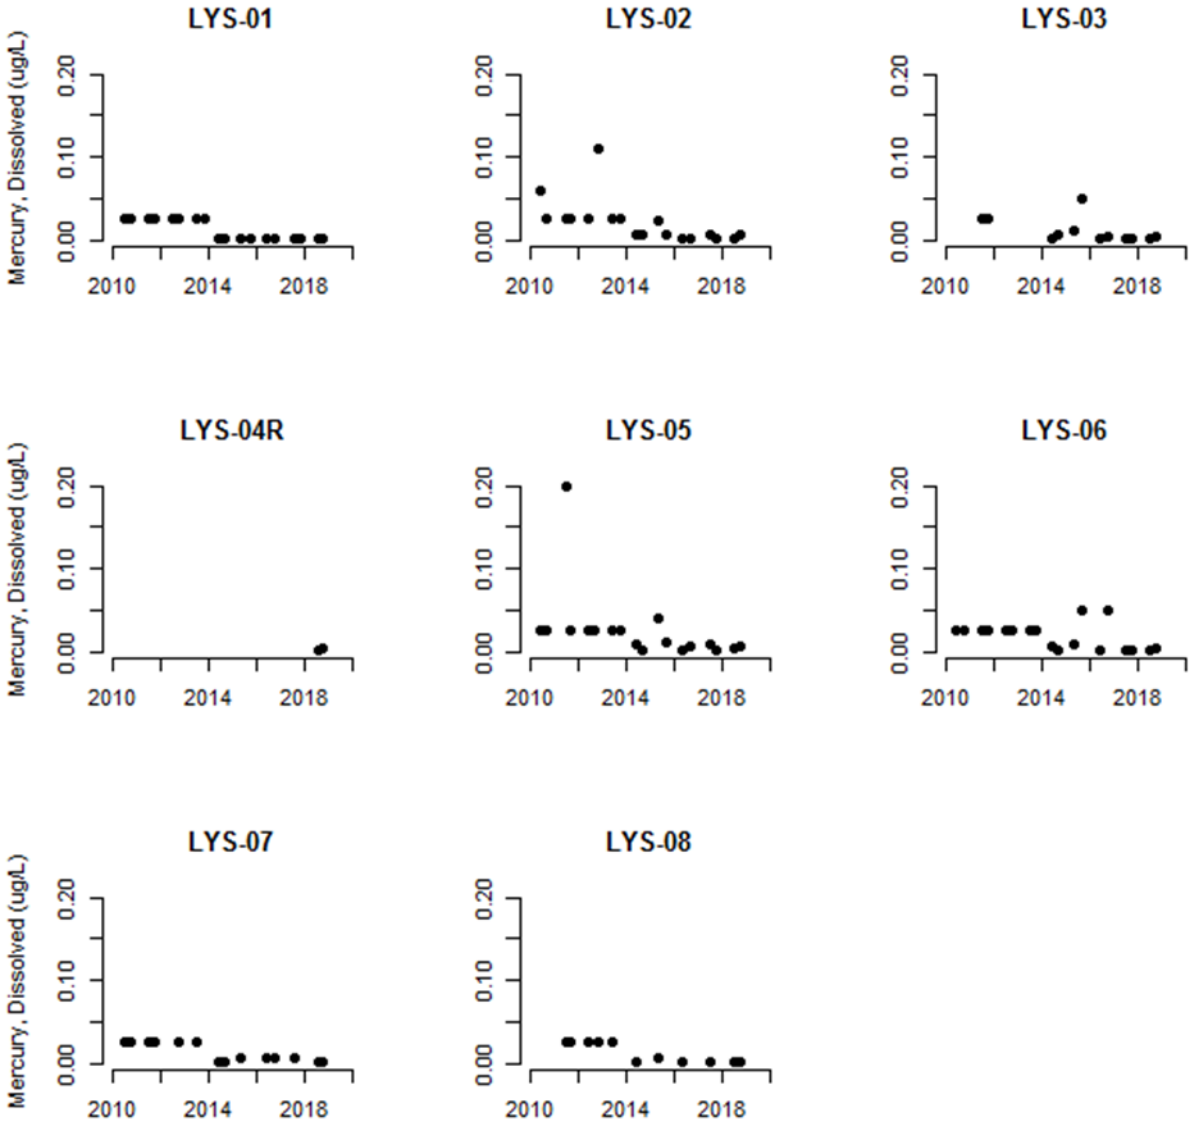

Figure 4-6. Mercury concentrations in lysimeters of the Mine Waste Relocation Repository in the Streamside Tailings Operable Unit (2010–2018).

4.4.6 Zinc

In 2018, zinc concentrations in each MWRR lysimeter were similar to previous years with the exception of LYS-06, which spiked at 0.106 mg/L in July 2018 (Figure 4-7). No lysimeters appeared to have increasing zinc concentrations over time (Figure 4-7).

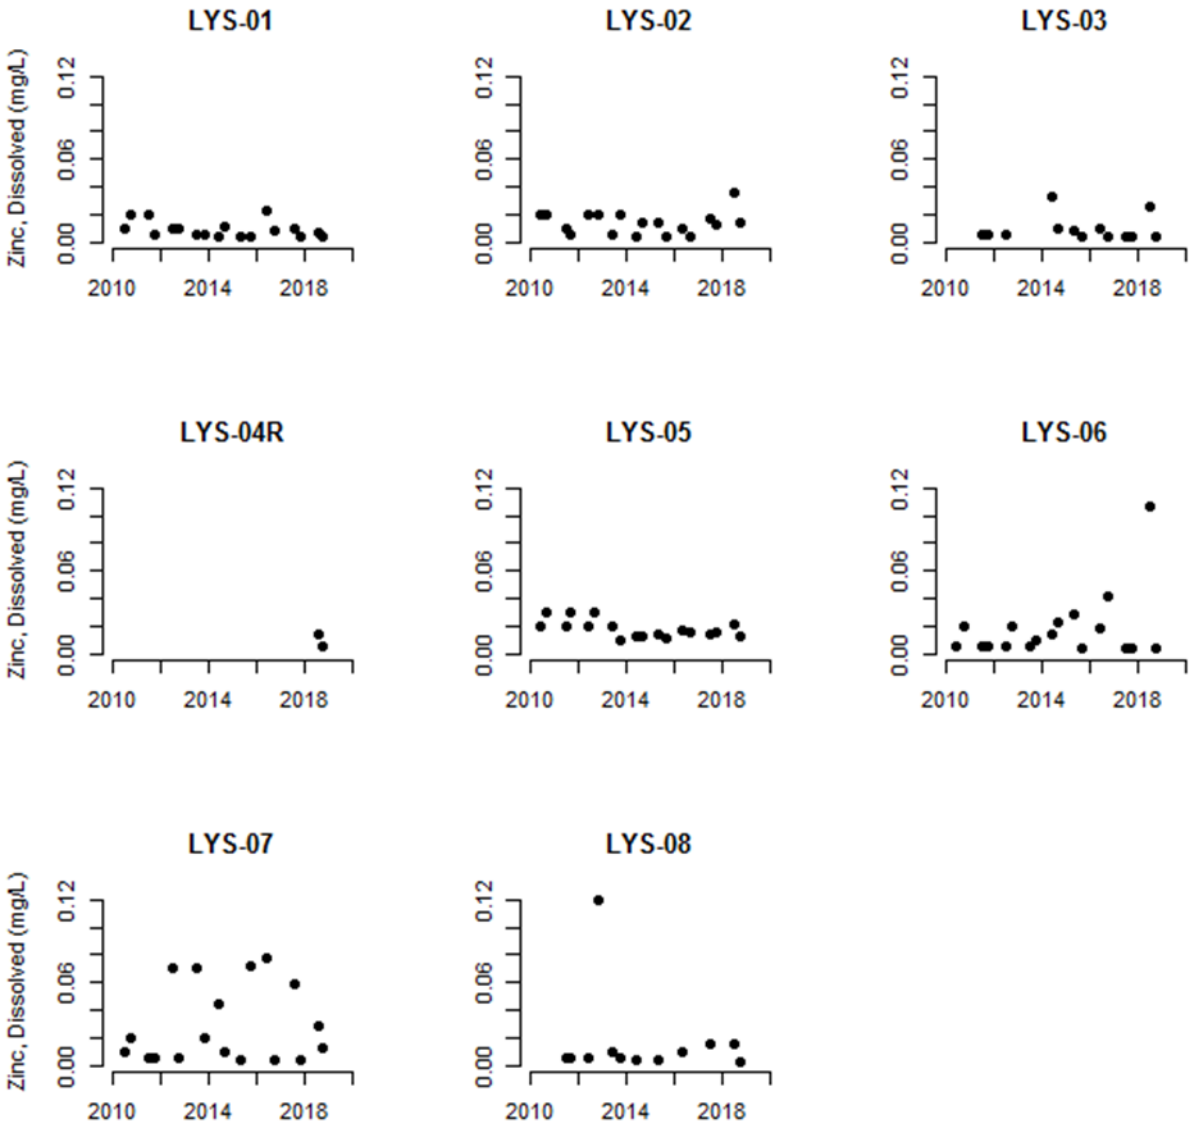

Figure 4-7. Zinc concentrations in lysimeters of the Mine Waste Relocation Repository in the Streamside Tailings Operable Unit (2010–2018).

4.5 DISCUSSION

4.5.1 Contaminants of Concern

Vadose zone sampling is conducted to provide advance notice in the event of COC releases from the repository which might threaten groundwater or surface water. In general, each COC concentration in each lysimeter was similar in 2018 to previous monitoring years, which indicates little inter-annual variability in vadose zone COC concentrations in the MWRR

Based on the 9-year time series at each lysimeter, COC concentrations generally do not appear to be increasing with the exceptions of copper at LYS-02 and arsenic at LYS-03. However, extrapolating temporal trends in COC concentrations from the 2010 to 2018 time period to more extended time periods (e.g., through 2030) may not be appropriate. Concentrations in both lysimeters will be monitored in future years to look for continued increasing trends.

4.5.2 Data Validation

Quality assurance and quality control results for vadose zone water are combined with groundwater (see Sections 3.4.3 and 3.5.3).

5.0 MACROINVERTEBRATES[53]

5.1 INTRODUCTION

Silver Bow Creek is a tributary to the Clark Fork River that extends from Butte, Montana approximately 23 miles downstream to the Warm Springs Ponds just north of Opportunity, Montana. Silver Bow Creek was impacted by mining waste and municipal sewage inputs from the 1870s through the 1980s. The earliest impacts resulted from underground mining and included waste rock, slag, and mill tailings that were deposited directly into the stream. In 1908 a major flood redistributed the waste rock and tailings downstream throughout the channel and floodplain. Mining efforts in the area shifted to open-pit operations with the 1955 opening of the Berkeley Pit mine near Butte. Open-pit mining ceased in the Berkeley Pit in 1982; however, copper precipitate is currently mined from the waters of the Berkeley Pit and mining continues in the nearby Continental Pit (molybdenum and copper). The ancestral headwaters of Silver Bow Creek have now been entirely subsumed into the Berkeley and Continental Pits and the city of Butte metro sewer system.

Silver Bow Creek and its adjacent floodplain have undergone major remediation that included excavation and removal of tailings and impacted soils from the floodplain, replacement of the removed tailings with local fill material, seeding and planting of vegetation, and reconstruction of the stream channel. Major remediation was completed in all subareas during 2017, but minor remedial actions occurred in Subareas 1 and 2 to remove some remnant tailings. The portion of the creek and its adjacent floodplain undergoing remediation is designated the Streamside Tailings Operable Unit (SSTOU) and is divided into four subareas. Remediation has already been accomplished in some subareas. A plan was established to monitor several factors as remediation progressed including surface water, instream sediments, geomorphology, groundwater, and aquatic biologic resources. Aquatic invertebrates are major components of the biota present in Silver Bow Creek and thus play important roles in the comprehensive monitoring plan. General performance goals have been stated for aquatic invertebrates in Silver Bow Creek: the assemblages should reflect a "balanced, integrated, adaptive community of organisms having a species composition, diversity, and functional organization comparable to that of the natural habitat of the region" [Karr and Dudley, 1981].

This report describes the analysis of a subset of the aquatic invertebrate monitoring program, specifically the samples collected from Silver Bow Creek in 2018. The benthic invertebrate fauna were analyzed with a number of biointegrity metrics which were combined into three indices, the Montana Foothills and Valley Prairies (MVFP) bioassessment index which was developed to evaluate the biological integrity of montane streams [Bollman, 1998], a modification of the Hilsenhoff Biotic Index [Hilsenhoff, 1987], which has a long history in biomonitoring studies, and the metals tolerance index [McGuire, 2009], which is specifically designed to examine metal

[53] Chapter 5 was prepared by B. Kerans and W. Bollman of Rhithron Associates Inc. (Missoula, Montana) with minor editing and formatting by RESPEC.

pollution. In addition to these indices, the sites were also evaluated using the Montana O/E model where O is the probability of capture for taxa collected in a sample and E is the probability of capture for taxa expected at a site of similar type that has not been negatively impacted by environmental stressors. Site-specific narratives were used to gain information about probable stressors to water quality and habitat integrity. These narratives were based on taxonomic and functional composition of the benthic fauna.

5.2 METHODS

5.2.1 Sampling

Aquatic invertebrates were sampled at 16 sites in the Silver Bow Creek watershed (Table 5-1) from August 29-30, 2017. Samples were delivered to Rhithron Associates (Missoula, Montana) for processing and identification.

Table 5-1. Macroinvertebrate sampling locations in the Streamside Tailings Operable Unit, September 17-21, 2018.

5.2.2 Laboratory Analysis

Subsamples of 500 (±10 percent) organisms were obtained: Caton sub-sampling devices [Caton, 1991], divided into 30 grids, each approximately six cm by six cm were used. Each individual

sample was thoroughly mixed in its jar(s), poured out and evenly spread into the Caton tray, and individual grids were randomly selected. The contents of each grid were examined under stereoscopic microscopes (Leica S6) using 10x-30x magnification. All aquatic invertebrates from each selected grid were sorted from the substrate and placed in 80 percent ethanol for subsequent identification. Grid selection, examination, and sorting continued until at least 500 (±10 percent) organisms were sorted. The final grid was completely sorted of all organisms. All unsorted sample fractions were retained and stored at the Rhithron laboratory.

Organisms were individually examined by certified taxonomists, most using 10x-80x stereoscopic dissecting scopes (Leica S8E) and identified to the lowest practical level consistent with DEQ [DEQ, 2012b] data requirements, using appropriate published taxonomic references and keys. After slide-mounting, representative specimens of midges and worms were further examined at 200x to 1000x magnification using Leica DM1000 or Olympus BX 51 compound microscope.

Identification, counts, life stages, and information about the condition of specimens were recorded on electronic bench sheets. Organisms that could not be identified to the taxonomic targets because of immaturity, poor condition, or lack of complete, current, and/or regionally-applicable published keys were left at appropriate taxonomic levels that were coarser than those specified. To obtain accuracy in richness measures, these organisms were designated as "not unique" if other specimens from the same group could be taken to target levels. Organisms designated as "unique" were those that could be definitively distinguished from other organisms in the sample. Identified organisms were preserved in 80 percent ethanol in labeled vials or, when appropriate, slide mounted and archived at the Rhithron laboratory.

5.2.3 Quality Assurance Systems

Quality control (QC) procedures for initial sample processing and subsampling involved checking sorting efficiency. These checks were conducted on two of the samples by independent technicians who microscopically re-examined 100 percent of sorted substrate from each sample. Quality control procedures for each sample proceeded as follows:

The quality control technician poured the sorted substrate from a processed sample out into a Caton tray. Portions of substrate were systematically removed and re-examined until 100 percent of the substrate was re-sorted. All organisms that were missed were counted and this number was added to the total number obtained in the original sort. Sorting efficiency was evaluated by applying the following calculation:

$$SE = \frac{n_1}{n_1 + n_2} \times 100$$

where: SE is the sorting efficiency (percent), n_1 is the total number of specimens in the first sort, and n_2 is the total number of specimens obtained in the second sort.

Quality control procedures for taxonomic determinations of invertebrates involved checking accuracy, precision and enumeration. Two samples were randomly selected, and all organisms re-identified and counted by an independent taxonomist. Taxa lists and enumerations were compared by calculating a Bray-Curtis similarity statistic [Bray and Curtis, 1957] for each selected sample. The percent taxonomic disagreement (PTD) and percent difference in enumeration (PDE) parameters were also calculated. Routinely, discrepancies between the original identifications and the QC identifications are discussed among the taxonomists, and necessary rectifications to the data are made. Discrepancies that cannot be rectified by discussions are routinely sent out to taxonomic specialists for identification. However, taxonomic certainty for identifications in this project was high and no external verifications were necessary.

5.2.4 Data Analysis

Taxa lists and counts for each sample were constructed. Approximately 72 standard metric expressions of taxonomic, functional, and behavioral characteristics as well as tolerance attributes were calculated, using a customized laboratory information system application. Aquatic invertebrate metrics included the Hilsenhoff Biotic Index (HBI), with tolerance values and impact threshold modified for Montana fauna [McGuire, 2010], and the Metals Tolerance Index (MTI) which was developed by McGuire [2010] for the Clark Fork River watershed. Table 5-2 shows scoring criteria applied by McGuire for these metrics.

Table 5-2. Hilsenhoff Biotic Index (HBI) and Metals Tolerance Index (MTI): metrics modified and developed by McGuire [2010] for assessing biological integrity in the Clark Fork River basin.

Metric	"no impact" ----------"severe impact"						
HBI	<4.0	4.0 – 4.5	4.6 – 5.1	5.2 – 5.7	5.8 – 6.3	6.4 – 6.9	>6.9
MTI	<4.0	4.0 – 4.9	5.0 – 5.9	6.0 – 6.9	7.0 – 7.9	8.0 – 8.9	>8.9

In addition to these metrics, the sites were also evaluated using the Montana O/E model where O is the probability of capture for taxa collected in a sample and E is the probability of capture for taxa expected at a site of similar type that has not been negatively impacted by environmental stressors. Thus, the O/E model was used to test how far a given macroinvertebrate community (O) deviates from those sampled at reference sites (E). To derive the O/E ratio, the model application R code [DEQ, 2012b] was used. The O/E index varies between zero (no organisms are collected) and one (the observed number of taxa is equal to the number of taxa expected at reference sites). In Montana, the O/E index is scored as pass/fail. In montane and transition zones, an O/E score at least 0.90 is a "pass" and a score of less than 0.90 is a "fail." An explanation of the theory and processes of the model is included in Feldman and Jessup [2012].

A multimetric index (Montana Valley and Foothill Prairies (MVFP) bioassessment index) was also used to examine the data [Bollman, 1998]. Six calculated metrics (Table 5-3) are the index components. The MVFP index is a quantitative measure which may be useful in assessing progress toward attainment of the general remediation goal of a "balanced, integrated, adaptive

community" of aquatic invertebrates, as envisioned by Karr and Dudley [1981]. To arrive at an MVFP index score and impairment classification, each component metric value was calculated, based on the taxonomic, functional, and tolerance attributes of the aquatic invertebrate assemblage, and categorical scores are assigned to each metric. Metric scores were summed for a total score, which was expressed as a percentage of the maximum total score. The percentages were then used to classify sites into impairment categories according to the following scenario: at least 83 percent was classified as "unimpaired"; 54-83 percent was classified as "slightly impaired"; 21-50 percent was classified as "moderately impaired"; and less than or equal to 17 percent was classified as "severely impaired".

We used graphical methods to compare all index scores among sites for 2018. In addition, we also examined temporal changes in the assessment tools within sites.

Table 5-3. Component metrics and scoring scheme for the aquatic invertebrate-based Montana Valley and Foothill Prairies (MVFP) bioassessment index [Bollman, 1998].

Metric	Metric score			
	3	2	1	0
	Metric values			
Ephemeroptera richness	>5	5 – 4	3 – 2	<2
Plecoptera richness	>3	3 – 2	1	0
Trichoptera richness	>4	4 – 3	2	<2
Number of sensitive taxa	>3	3 – 2	1	0
Percent filterers	0 - 5	5.01 – 10	10.01 – 25	>25
Percent tolerant taxa	0 - 5	5.01 - 10	10.01 - 35	>35

5.2.5 Ecological Interpretations: Approach

Narrative interpretations of taxonomic and functional composition of invertebrate assemblages were used to reveal the probable stressors in the SSTOU. Often canonical procedures are used for stressor identification; however, the substantial data required for such procedures (e.g., surveys of habitat, historical and current data related to water quality, land use, point and non-point source influences, soils, hydrology, geology) were not readily available for this study. Instead our narrative interpretations are based on demonstrated associations between assemblage components and habitat and water quality variables gleaned from the published literature, the authors' own research and professional judgment, and the research and professional judgment of other expert sources. We did not refer to habitat assessments or any other SSTOU data while crafting these narratives.

Attributes of invertebrate taxa that are well substantiated in diverse literature and that are generally accepted by regional aquatic ecologists as evidence of water quality and instream and reach-scale habitat conditions were used. The approach to this analysis uses some assemblage attributes that are interpreted as evidence of water quality and other attributes that are

interpreted as evidence of habitat integrity. To arrive at impairment classifications, attributes are considered individually, so information is maximized by not relying on a single cumulative score, which may mask stress on the biota. Such an approach also minimizes the possibility of using inappropriate assessment strategies when the biota at a site is atypical of "characteristic" sites in a region. Below we describe the invertebrate attributes that were used and their relationships to water quality and habitat conditions.

Mayfly taxa richness, the Hilsenhoff Biotic Index (HBI) value [Hilsenhoff, 1987], the richness and abundance of hemoglobin-bearing taxa and the richness of pollution sensitive taxa are often used as indicators of water quality. Mayfly taxa richness has been demonstrated to be significantly correlated with chemical measures of dissolved oxygen, pH, and conductivity (e.g., Fore et al. [1996]; Wisseman [1996]; Bollman [1998]). The HBI has a long history of use and validation [Cairns and Pratt, 1993; Smith and Tran, 2010; Johnson and Ringler, 2014]. In Montana foothills, the HBI was demonstrated to be significantly associated with conductivity, pH, water temperature, sediment deposition, and the presence of filamentous algae [Bollman, 1998]. Nutrient enrichment in Montana streams often results in large crops of filamentous algae [Watson, 1988]. Thus, in these samples, when macroinvertebrates associated or dependent on filamentous algae (e.g., LeSage and Harrison [1980]; Anderson [1976]) are abundant, the presence of filamentous algae and nutrient enrichment are also suspected. Pollution sensitive taxa exhibit intolerance to a wide range of stressors (e.g., Wisseman [1996]; Hellawell [1986]; Friedrich [1990]; Barbour et al. [1999]), including nutrient enrichment, acidification, thermal stress, sediment deposition, habitat disruption, and others. These taxa are expected to be present in predictable numbers in functioning montane and foothills streams (e.g., Bollman [1998]). Although the abundance of invertebrates in Hess samples can be highly variable, reflecting the patchy and dynamic areal distribution of the benthos in stony-bottomed streams, McGuire's thresholds for environmental perturbation [McGuire, 2010] are cited as evidence of enrichment or impairment.

The absence of invertebrate groups known to be sensitive to metals and the Metals Tolerance Index [Bukantis, 1998] are considered signals of possible metals contamination. Metals sensitivity for some groups, especially the heptageniid mayflies, is well-known (e.g., Kiffney and Clements [1994]; Clements [1999]; Clements [2004]; Montz et al. [2010]; Iwasaki et al. [2013]). In the present approach, the absence of these groups in environs where they are typically expected to occur is considered a signal of possible metals contamination, but only when combined with a measure of overall assemblage tolerance of metals. The Metals Tolerance Index ranks taxa according to their sensitivity to metals. Weighting taxa by their abundance in a sample, assemblage tolerance is estimated by averaging the tolerance of all sampled individuals.

The richness and abundance of cold stenotherm taxa [Clark, 1997] and calculation of the temperature preference of the macroinvertebrate assemblage [Brandt, 2001] can predict the thermal characteristics of the sampled site. Hemoglobin-bearing taxa are also indicators of warm water temperatures [Walshe, 1947], since dissolved oxygen is directly associated with water temperature; oxygen concentrations can also vary with the degree of nutrient enrichment. Increased temperatures and high nutrient concentrations can, alone or in concert, create conditions favorable to hypoxic sediments, habitats preferred by hemoglobin-bearers.

Characteristics of the macroinvertebrate assemblages can also reveal the condition of instream and streamside habitats. Stress from sediment deposition is evaluated by caddisfly richness and by "clinger" richness [Kleindl, 1995; Bollman, 1998; Karr and Chu, 1999; Wagenhoff et al., 2012; Leitner et al., 2015]. We also used two indices to examine the presence of fine sediment. The first is an index developed by Relyea et al. [2000]. We include this index for comparative purposes because it has been used in past reports. It uses habitat associations of the biota to characterize the assemblage. The index, which we call the FSBI-2000, varies between one and 10.5 with lower scores indicating assemblages that are tolerant of fine sediment and higher scores indicating assemblages that are intolerant of fine sediment. The FSBI-2000 should now be replaced by a newer index. Relyea et al. [2012] developed a new index that is also called a fine sediment biotic index (we refer to this index as the FSBI-2012). This index was developed based on data from benthic macroinvertebrate assemblages and substrate particle size data collected from 1,139 streams in the northwestern U.S. Taxa were given an FSBI-2012 score based on their relationship to fine particles. The FSBI-2012 varies between zero and 400 with high scores indicating habitats with fewer fine sediments. The interpretations of these indices are modified in this report, based on the authors' professional judgments, to more effectively characterize the SSTOU in the sampled reaches. In addition, characteristics of assemblages can suggest whether other disturbances might influence stream-side vegetation, if disturbances other than sedimentation could influence stream fauna, or if stream bottoms have diverse habitats that support diverse invertebrate assemblages.

Finally, the functional characteristics of macroinvertebrate assemblages are based on the morphology and behaviors associated with feeding, and they are interpreted in terms of the River Continuum Concept [Vannote et al., 1980] in the narratives. Alterations from predicted patterns in montane and foothills streams may be interpreted as evidence of water quality or habitat disruption. For example, shredders and the microbes they depend on are sensitive to modifications of the riparian zone [Plafkin et al., 1989].

5.3 RESULTS

5.3.1 Quality Assurance Systems

Results of internal quality control procedures for subsampling and taxonomy for aquatic invertebrate samples are given in Table 5-4. Sorting efficiency averaged 97.4 percent for the quality control samples in this project. The similarity between original identifications and enumerations for the two quality control samples averaged 97.3 percent. Percent taxonomic disagreement (PTD) averaged 3.4 percent, and the percent difference in enumeration (PDE) averaged 0.7 percent. Rhithron's internal quality standards, consistent with industry norms, are: for sorting efficiency, at least 95 percent; for Bray-Curtis similarity, at least 95 percent; for PTD, not more than 5 percent; and for PDE, not more than 5 percent [Stribling et al., 2003].

Table 5-4. Results of quality assurance systems parameters for aquatic invertebrate samples. Silver Bow Creek watershed, September 17-21, 2018.

Site ID	Station name	Sorting efficiency (%)	Bray-Curtis similarity (%)	Percent taxonomic disagreement (%)	Percent difference in enumeration (%)

5.3.2 Bioassessment

Values for the six MVFP aquatic invertebrate metrics are shown in Table 5-5. MVFP scores and associated impairment classifications are given in Table 5-6. Figure 5-1 graphs the 2018 MVFP scores, as percent of maximum possible score, for all sites in the study. One site (Site SS-15G; German Gulch near confluence) was rated "non-impaired." Site SS-08 (Silver Bow Creek at Rocker) was rated "severely" impaired. All other sites were rated "moderately" impaired. Site SS-15G had higher mayfly, stonefly and pollution-sensitive taxa (none were collected at any other site) diversities than any other site. In addition, Site SS-15G had the lowest percentage of pollution-tolerant taxa than any other site. The severely impaired site (Site SS-08) exhibited low

mayfly, stonefly and pollution sensitive taxa richnesses combined with high percentages of filterers and pollution-tolerant organisms. Interestingly, the sites with the lowest MVFP scores that were still given a "moderate" rating (22.2 percent at Sites SS-05A, SS-05G, SS-07, SS-10A, and SS-11C) were located upstream and downstream of Site SS-08 and differed from SS-08 by having slightly fewer pollution-tolerant organisms. Trichoptera diversity was typically high regardless of the overall MVFP score.

The O/E metric classified all sites as impaired (Table 5-6). Sites SS-15B (Silver Bow Creek below German Gulch) and SS-15G (German Gulch near confluence) had O/E scores of 0.65 and 0.77, respectively. Although these were the highest O/E scores attained in 2018, they were still below the impairment threshold of 0.90.

HBI metric values were elevated relative to the impact threshold for nutrients determined by McGuire [2010] at 10 sites in 2018 (Figure 5-2). Sites SS-15A-2, SS-15B, SS-15G, SS-16B, SS-17D, and SS-19 were below the threshold value. Interestingly, the general trend was for upstream sites to have higher HBI values than downstream sites. No sites had exceptionally high (more than 6.0) values for the HBI; only Site SS-13 had an HBI value over 5.0.

MTI metric values for seven sites (Sites SS-01, SS-05A, SS-06G, SS-07, SS-08, SS-10A, and SS-11C) were elevated relative to the impact threshold for metals determined by McGuire [2010] (Figure 5-3). Nine sites (Sites SS-11D, SS-13, SS-14D, SS-15A-2, SS-15B, SS-15G, SS-16B, SS-17D, and SS-19) generated MTI values that indicated no impact from metals contamination, according to McGuire's guidance. Again, the general pattern is for upstream sites to have higher values than the downstream sites.

Table 5-5. Montana Valley and Foothill Prairies [Bollman, 1998] metric results: Silver Bow Creek, September 17-21, 2018.

Site ID	Site Location	Metric					
		Ephemeroptera richness	Plecoptera richness	Trichoptera richness	Number of sensitive taxa	Percent filterers	Percent tolerant taxa

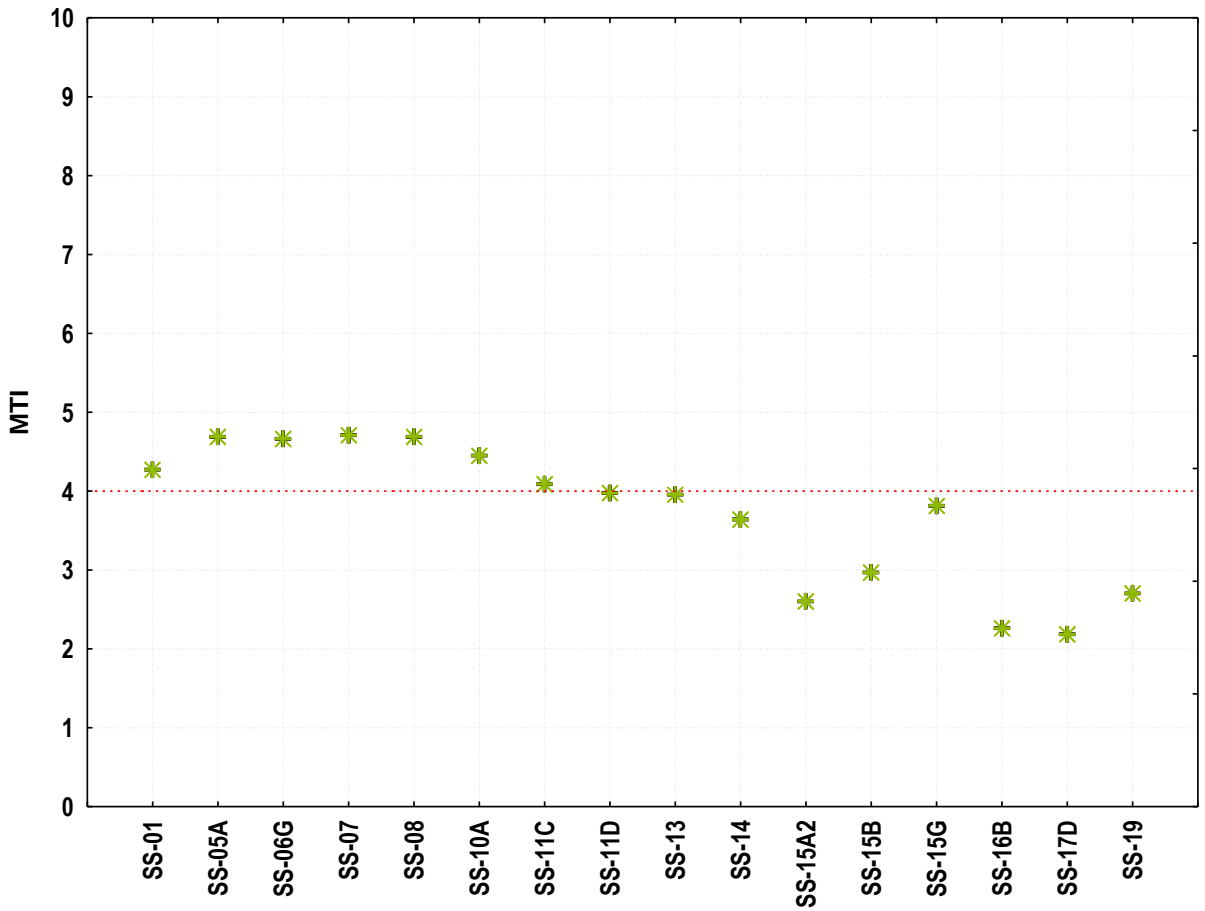

Figure 5-3. Metals tolerance index (MTI) values: comparison among sites. The red dashed line represents the presumed impact threshold determined for the Clark Fork River basin [McGuire, 2009]. Silver Bow Creek watershed, September 17-21, 2018.

5.3.3 Temporal Comparisons and Ecological Interpretations

5.3.3.1 SS-01: Blacktail Creek at Father Sheehan Park

5.3.3.1.1 Comparisons among years

MVFP bioassessment scores (Figure 5-4) varied from year to year at Site SS-01. However, the 2018 score continued the increasing trend that was seen in 2017. Severe impairment was indicated in 2013 with moderate impairment indicated between 2014 and 2018. The MTI indicated slight impairment from metals in every year since 2010 according to McGuire's guidance (Figure 5-5). The HBI indicated mild-to-moderate nutrient enrichment in most years over the same period (Figure 5-5).

5.3.3.1.2 2018 Data

5.3.3.1.2.1 Water quality

Only three mayfly taxa were collected here: the ubiquitous *Baetis tricaudatus* complex (2.8 percent) was abundant, whereas *Ephemerella excrucians* (0.6 percent) and *Callibaetis* species (0.2 percent) were rare. The HBI (4.58) was higher than expected for a low-order Middle Rockies stream and the percentage of collector-filterers (38.4 percent) was much higher than expected. In addition, midges in the genus *Orthocladius* (6.2 percent) and the annelid worms *Nais* species (1.9 percent) were abundant: these taxa suggested the presence of filamentous algae, large crops of which may be associated with nutrient enrichment. Organisms containing hemoglobin (3.0 percent) were also common suggesting that sediments may have been hypoxic. No pollution-sensitive taxa were collected and pollution-tolerant organisms (mostly the elmid beetle, *Optioservus* (12.3 percent)) composed 16.0 percent of the assemblage. The high HBI, high relative abundances of collector-filterers and animals that inhabit filamentous algae, and the commonness of hemoglobin-bearing organisms suggested that water quality was impaired through nutrient enrichment and that sediments may have been hypoxic. The MTI (4.27) exceeded the impairment threshold [McGuire, 2009]: metals contamination may have occurred here.

5.3.3.1.2.2 Thermal condition

No cold-stenotherm taxa and a few specimens of the warm-water loving snail *Stagnicola* species (0.4 percent) and caddisfly *Oecetis* species (0.4 percent) were collected. The thermal preference of the aquatic invertebrate assemblage was 15.3 C.

5.3.3.1.2.3 Sediment deposition

The FSBI-2000 (5.62) indicated an assemblage that was moderately intolerant of fine sediments and the FSBI-2012 (35) provided little evidence that fine sediments dominated the stony stream bottom in this reach. At least 5 caddisfly and 15 "clinger" taxa were collected. *Brachycentrus americanus* (29.1 percent) was the most abundant taxon in the sample and was the only abundant trichopteran. Because only 5 caddisfly taxa were found, slight impediment of

invertebrate colonization of the stony stream bottom by fine sediment could not be ruled out at this site, even though the FSBI-2000 indicated a moderately sediment-intolerant assemblage.

5.3.3.1.2.4 Habitat diversity and integrity

Instream habitats at this site appeared to be diverse and intact as overall taxa richness (47) was relatively high. Two stonefly taxa (an unidentified chloroperlid and *Skwala* species) were collected, but both were uncommon (0.4 percent) indicating that channel morphology may be altered, streambanks may be unstable and riparian function may be disturbed. Five semivoltine taxa were collected from this site: both the elmid beetle *Optioservus* (12.3 percent) and the caddisfly *Brachycentrus americanus* were very abundant making catastrophic dewatering or thermal extremes seem unlikely. The importance of fine particulate organic matter to the food web was indicated by the abundances of collector-filterers (38.4 percent, the dominant functional group) and collector-gatherers (29.6 percent). In addition, scrapers (13.4 percent) were also abundant, which may indicate an open canopy and that autochthonous algal production may have also been important to the food web. However, shredders (2.8 percent) were underrepresented which may indicate that insignificant amounts of large sized allochthonous material entered from the riparian zone or that such material was not retained in this reach.

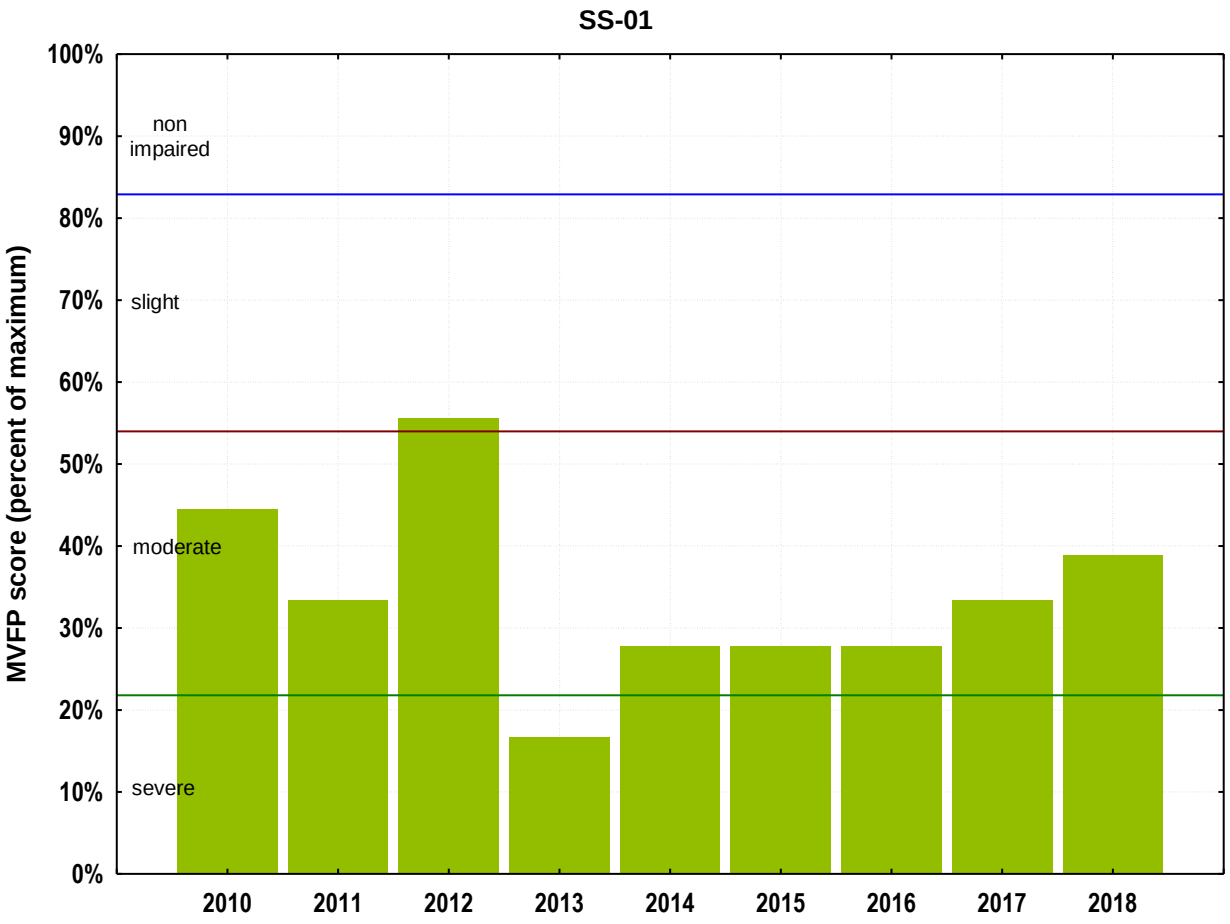

Figure 5-4. Montana Valley and Foothill Prairies (MVFP) bioassessment scores: comparison among years for Site SS-01. Bars are labeled with impairment classifications.

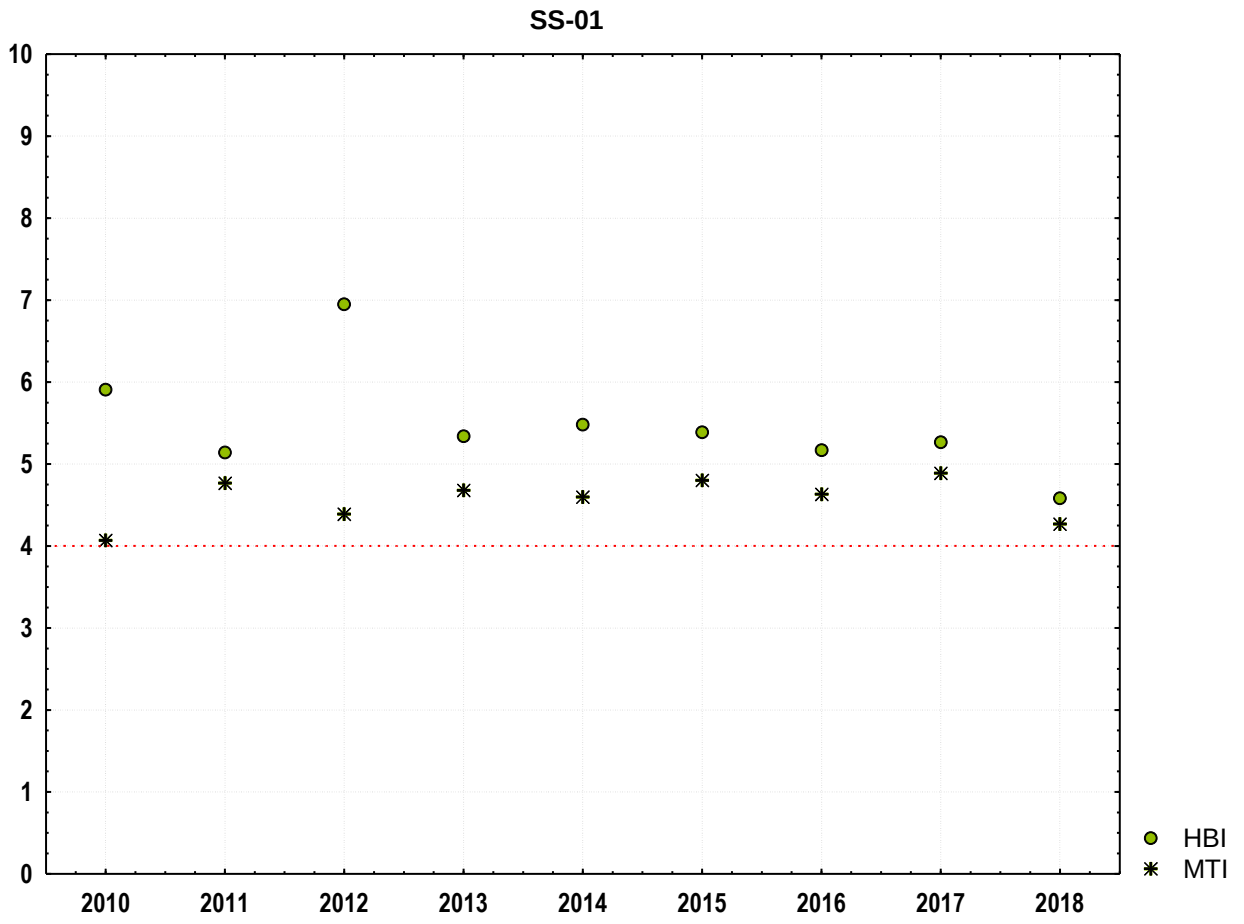

Figure 5-5. Hilsenhoff Biotic Index (HBI) and metals tolerance index (MTI) values: comparison among years for Site SS-01. The red dashed line represents the "no impact" threshold for both metrics established by McGuire for the Clark Fork River basin.

5.3.3.2 SS-05A: Silver Bow Creek above Butte Reduction Works

5.3.3.2.1 Comparisons among Years

Like the MVFP bioassessment scores from 2015 to 2017, moderate impairment was indicated at Site SS-05A in 2018 (Figure 5-6). Low scores, suggesting severe impacts, were detected in 2013 and 2014, thus the 2015 through 2018 scores indicated an improvement in condition. According to McGuire's guidance, the MTI indicated slight impairment from metals in each year since sampling was begun (2012), and the HBI indicated moderate nutrient enrichment over the same time (Figure 5-7).

5.3.3.2.2 2018 Data

5.3.3.2.2.1 Water quality

The ecological characteristics of the invertebrate assemblage suggested that water quality was impaired in this reach. Mayflies were represented by only one taxon, the ubiquitous *Baetis tricaudatus* complex (10.1 percent), which was abundant. The HBI (4.90) was elevated, caddisflies in the family Hydroptilidae (2.6 percent) were abundant and collector-filterers (36.2 percent) were extremely abundant. The collection of many hydroptilid caddisflies, which suggested the presence of filamentous algae, and the abundance of collector-filterers in the sample both supported the contention that nutrient enrichment, suggested by the elevated HBI, impaired this reach. Hemoglobin-bearing organisms (0.9 percent) were present; thus, hypoxic sediments cannot be dismissed. No pollution-sensitive taxa were reported, and pollution-tolerant organisms composed 34.7 percent of the sample. The high HBI, commonness of hemoglobin-bearing organisms, and abundance of filamentous algae-loving organisms and collector-filterers suggested that nutrient enrichment was the cause of the reduction in water quality in this reach. Several specimens in the flatworm class Trepaxonemata (10, 1.8 percent) were collected, suggesting some inputs of ground water in this reach. Impact by metals may have occurred here, since the MTI (4.69) exceeded the impairment threshold [McGuire, 2009].

5.3.3.2.2.2 Thermal condition

The thermal preference of the aquatic invertebrate assemblage was 16.3 C. No cold-loving taxa were collected in this reach. Indeed, the warm-water preferring snail *Stagnicola* species (1.7 percent) and caddisfly *Oecetis* species (1.5 percent) were common at this site.

5.3.3.2.2.3 Sediment deposition

Twelve "clinger" and seven caddisfly taxa (6 associated with stony stream bottoms) were reported from the sample taken from this reach. Most of the caddisfly taxa were abundant or common including the filterers *Cheumatopsyche* species (16.2 percent) and *Hydropsyche* species (16.4 percent): these were the two most abundant taxa. The FSBI-2000 of 3.75 suggested a moderately sediment-tolerant invertebrate assemblage and the FSBI-2012 was 20, which provided little evidence for the dominance of fine sediment on the stony stream bottom. These data indicated that slight disruption of invertebrate colonization by the deposition of fine sediment could not be ruled out at Site SS-05A in 2018.

5.3.3.2.2.4 Habitat diversity and integrity

Taxa richness (33) was lower than expected and no stoneflies were collected in this reach. Thus, instream habitats were probably disrupted and/or monotonous and streambanks may have been unstable, channel morphology may have been altered, or riparian function may have been poor. Certainly, such low diversity could be influenced by poor water quality as well. It seems likely that catastrophes that would limit long life cycles were not influential here because six semivoltine taxa were reported. Of the long-lived taxa, the elmid beetle *Optioservus* species (12.9 percent) was abundant. Collector-filterers (36.2 percent) were the most abundant of the functional feeding groups. Collector-gatherers (19.7 percent) and scrapers (15.1 percent) also made up large percentages of the assemblage. The abundance of the mite predators (15.8 percent; *Acari*) resulted in a high relative abundance of predators (22.2 percent). Shredders (0.7 percent) were not well represented. Consequently, fine particulate organic matter and autochthonous algal production were both important to the energy flow in this system, whereas coarse particulate matter was not a large component of the food web: this suggests that inputs from the riparian zone were no significant, or that such material was not retained in this reach.

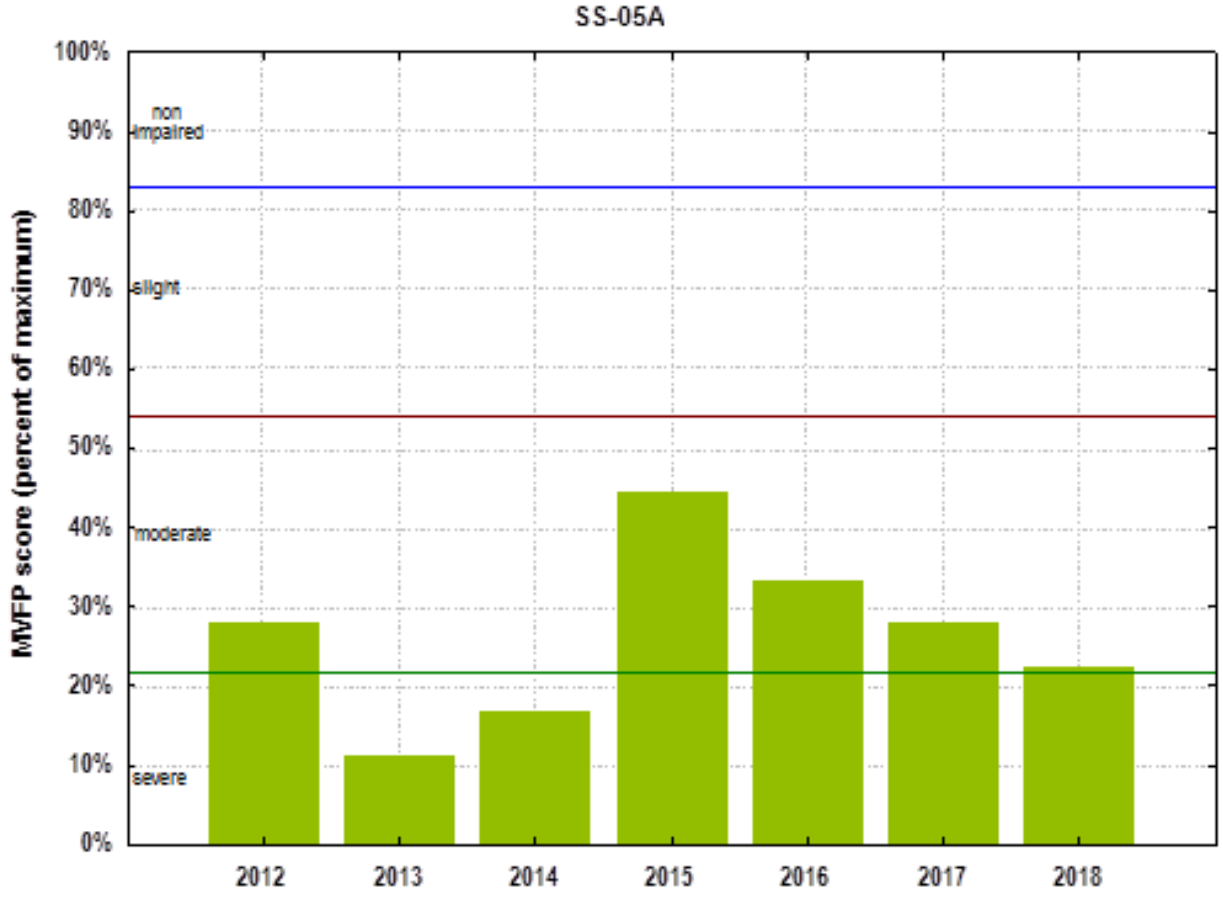

Figure 5-6. Montana Valley and Foothill Prairies (MVFP) bioassessment scores: comparison among years for Site SS-05A. Bars are labeled with impairment classifications.

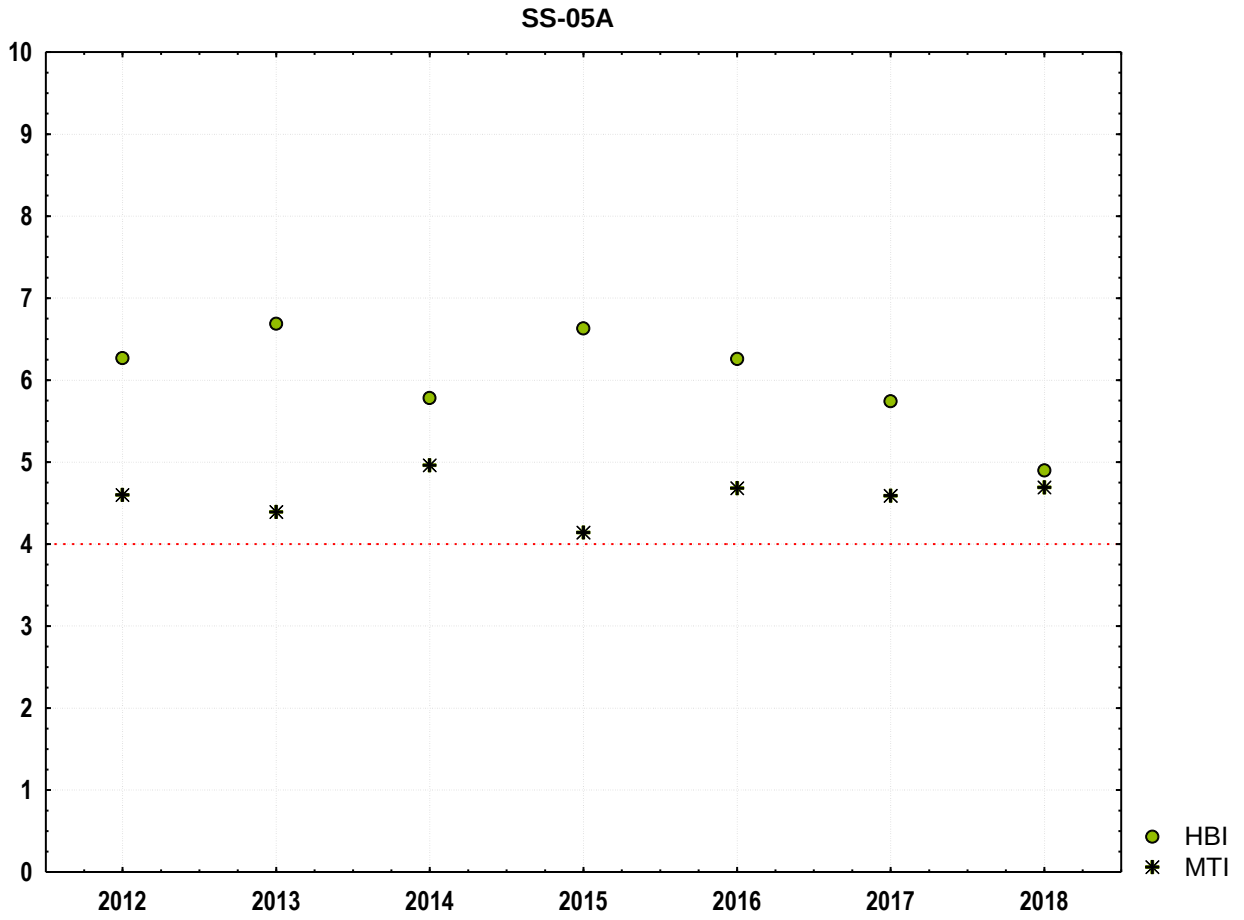

Figure 5-7. Hilsenhoff Biotic Index (HBI) and metals tolerance index (MTI) values: comparison among years for Site SS-05A. The red dashed line represents the "no impact" threshold for both metrics established by McGuire for the Clark Fork River basin.

5.3.3.3 SS-06G: Silver Bow Creek above Butte WWTP

5.3.3.3.1 Comparisons among Years

Moderate impairment was indicated by the MVFP bioassessment score at Site SS-06G in 2018. Since 2010 moderate impairment was indicated at this site only in 2011, 2016 and 2017; consequently, the 2016 through 2018 scores suggested an improvement in condition (Figure 5-8). According to McGuire's guidance, the MTI indicated slight impairment from metals in each year since 2012, and the HBI indicated mild-to-moderate nutrient enrichment since 2010 (Figure 5-9).

5.3.3.3.2 2018 Data

5.3.3.3.2.1 Water quality

Water quality appears to be impaired at Site SS-06G. The HBI (4.93) was above expectations and the ubiquitous *Baetis tricaudatus* complex (14.9 percent) was the only mayfly taxon reported from this site. Collector-filterers (55.3 percent), primarily the caddisflies *Hydropsyche* species (37.1 percent, the dominant taxon in the sample) and *Cheumatopsyche* species (10.9 percent), were also extremely abundant. These results suggested that nutrient enrichment impaired water quality. However, hypoxia in the sediments did not appear to occur because no hemoglobin-bearers were collected. Like many of the other sites visited in 2018, no pollution-sensitive taxa were collected and pollution-tolerant organisms (25.8 percent) were extremely abundant, also suggesting impacts to water quality. The MTI (4.66) was elevated, compared to the impairment threshold, thus metals contamination may be likely.

5.3.3.3.2.2 Thermal condition

Several specimens of the warm-water preferring snail *Stagnicola* species (0.9 percent) and caddisfly *Oecetis* species (1.1 percent) were collected and no cold-stenotherm taxa were found in the sample. The characteristics of the biota indicated that the thermal preference of the assemblage was 16.6 C.

5.3.3.3.2.3 Sediment deposition

"Clingers" were represented by 10 taxa and caddisflies were represented by seven taxa (6 associated with stony sediments). Of the caddisflies, *Cheumatopsyche* species, *Hydropsyche* species and *Amiocentrus aspilus* (5.5 percent) were all abundant, and *Oecetis* species was common. These characteristics, as well as an FSBI-2000 of 4.19, indicative of an invertebrate assemblage that was moderately tolerant of fine sediment, suggested that slight limitation of invertebrate colonization of the stony bottom by the deposition of fine sediment probably could not be ruled out here. The FSBI-2012 was 20, providing neither support for nor against the effects of the deposition of fine sediment on the assemblage.

5.3.3.3.2.4 Habitat diversity and integrity

Only 26 taxa were reported from this sample and none of them were stoneflies. Low overall taxa and stonefly diversities could be related to instream habitat disruption, reach-scale disturbances (e.g., altered channel morphology, unstable stream banks or disrupted riparian

zones), impaired water quality, or all three. Disasters like thermal extremes or scour seemed unlikely in this reach because 4 semi-voltine taxa were collected including the abundant elmid *Optioservus* (12.9 percent). Both collector-filterers (55.3 percent) and collector-gatherers (26.2 percent) were extremely abundant indicating the importance of fine particulate organic matter to the food web. Scrapers (13.8 percent) were also an abundant component of the food web; however, shredders (0.2 percent) were not well represented, suggesting that little large allochthonous material entered from the riparian zone or that such material was not retained in the reach.

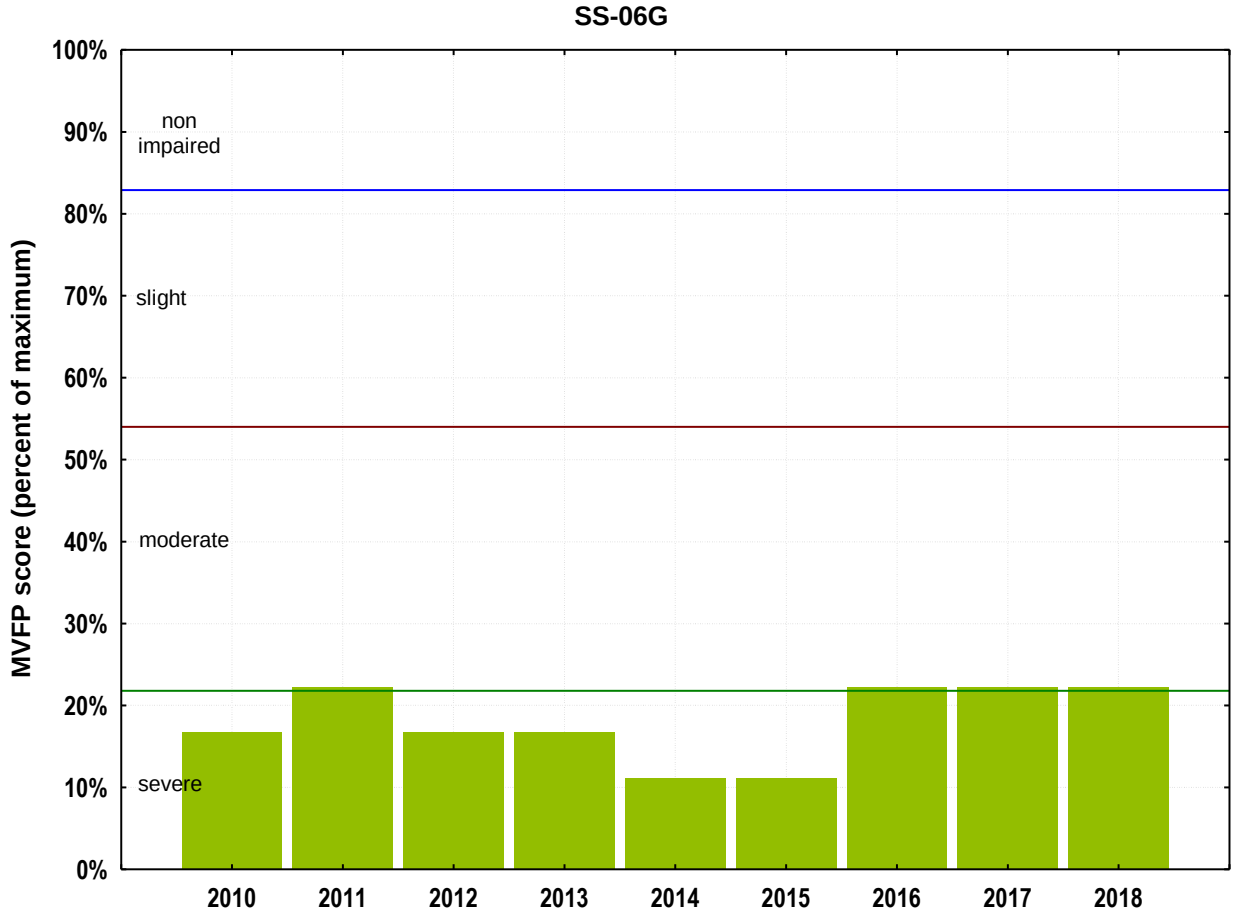

Figure 5-8. Montana Valley and Foothill Prairies (MVFP) bioassessment scores: comparison among years for Site SS-06G. Bars are labeled with impairment classifications.

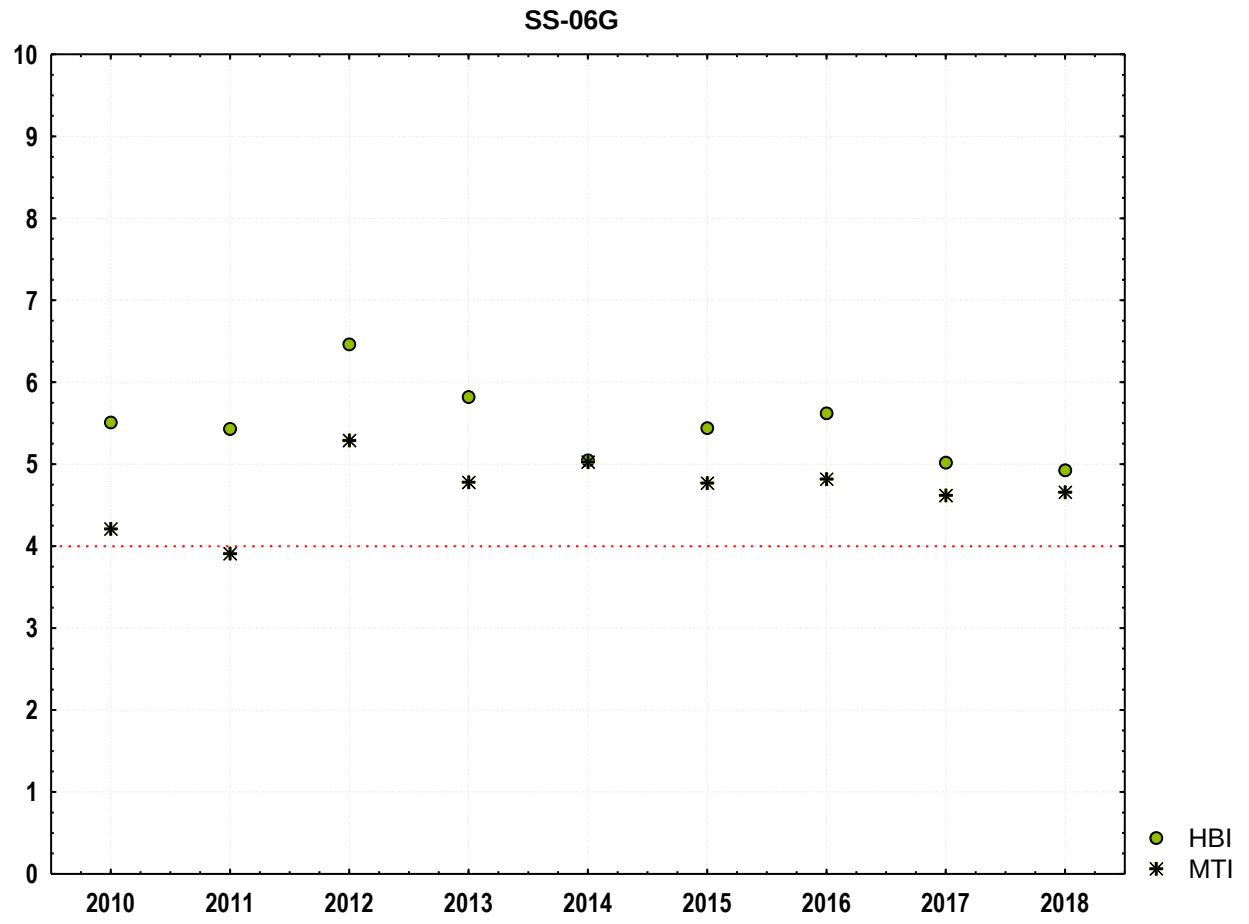

Figure 5-9. Hilsenhoff Biotic Index (HBI) and metals tolerance index (MTI) values: comparison among years for Site SS-06G. The red dashed line represents the "no impact" threshold for both metrics established by McGuire for the Clark Fork River basin.

5.3.3.4 SS-07: Silver Bow Creek below Butte WWTP

5.3.3.4.1 Comparisons among Years

As indicated by the MVFP bioassessment index, Site SS-07 was scored as moderately impaired in 2018 and moderate impairment was only indicated one other time: in 2016 (Figure 5-10). In all other years the MVFP indicated severe impairment. According to McGuire's guidance, the MTI indicated slight impairment from metals in most years since 2010. The HBI indicated moderate-to-severe nutrient enrichment since 2010, although the lowest HBI scores were recorded from 2016 to 2018 (Figure 5-11).

5.3.3.4.2 2018 Data

5.3.3.4.2.1 Water quality

The moderately elevated HBI (4.76), the collection of only one mayfly taxon (the ubiquitous *Baetis tricaudatus* complex, 22.2 percent), the absence of pollution-sensitive taxa, and the higher than expected percentages of collector-filterers (41.9 percent, mainly the caddisfly *Hydropsyche* species (36.4 percent) the dominant animal in the sample) and pollution-tolerant organisms (28.9 percent) suggested that water quality at this site was impaired. The low mayfly abundance, high HBI and high percentage of collector-filterers indicated that the impairment may have been related to high nutrient levels. There was little evidence of hypoxic sediments as only a few hemoglobin-bearing organisms (0.2 percent) were found. Contamination by metals may have occurred, as the MTI (4.71) exceeded the impairment threshold.

5.3.3.4.2.2 Thermal condition

Similar to all but one site sampled in 2018, no cold-loving taxa were found in this sample. Two specimens of the warm-water loving snail *Stagnicola* species (0.4 percent) were collected and the caddisfly *Oecetis* species (1.8 percent) was common. The thermal preference of the assemblage was 16.4 C.

5.3.3.4.2.3 Sediment deposition

The FSBI-2000 of 4.36 indicated an assemblage that was moderately tolerant of fine sediment. However, the FSBI-2012 score of 15 provided little evidence for or against the deposition of fine sediment on the stony stream bottom. Eight caddisfly taxa, seven of which were associated with stony stream bottoms, and 12 "clinger" taxa were recorded from this site. Many of the caddisflies were abundant (e.g., *Hydropsyche* species) or common (e.g., *Oecetis* species). Thus, slight hindrance of invertebrate colonization by fine sediment deposition could not be ruled out here.

5.3.3.4.2.4 Habitat diversity and integrity

The diversity (24 taxa) of the benthic fauna was low at this site and as with many of the other Silver Bow sites, no stoneflies were found in the sample. These results suggested that both instream and reach-scale habitats were disrupted. Poor water quality could also contribute to reduced taxa richness. Three semivoltine taxa were collected: only one specimen of the elmid beetle *Zaitzevia* species (0.2 percent) and a few specimens of the caddisfly *Brachycentrus*

occidentalis (0.7 percent) were collected, but the elmid beetle *Optioservus* species (23.9 percent) was the second most abundant organism in the sample. Catastrophic events such as thermal extremes seem unlikely here. Collectors (filterers, 41.9 percent; gatherers, 27.4 percent) dominated the functional composition of the assemblage. Lack of channel shading may have benefited the well-developed algal films that were suggested by the high relative abundance of scrapers (25.0 percent). Thus, fine particulate organic matter and autochthonous algal production were both important in the food web. Shredders (0.6 percent) were rare, implying that coarse particulate organic matter deposited mainly from stream-side vegetation contributed little to the food web.

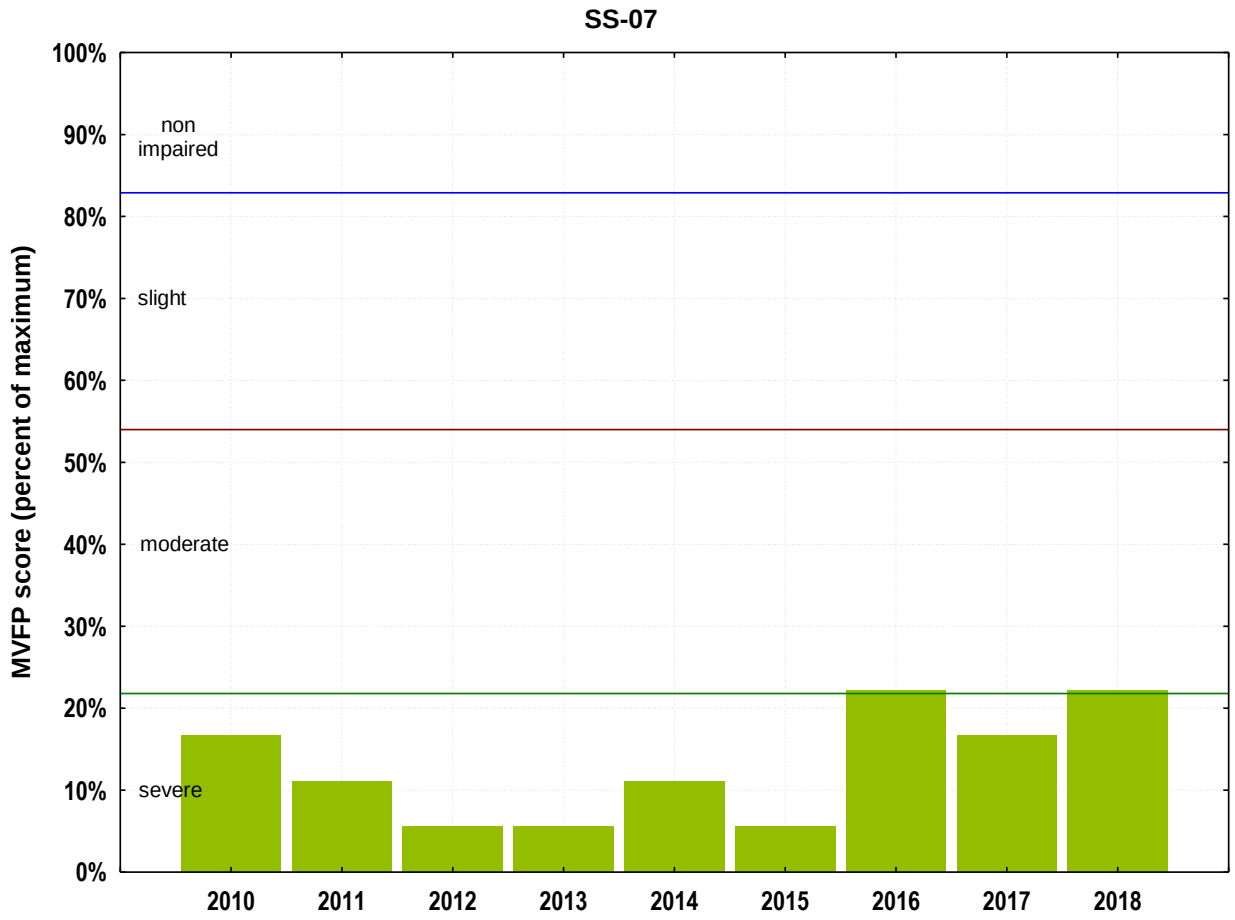

Figure 5-10. Montana Valley and Foothill Prairies (MVFP) bioassessment scores: comparison among years for Site SS-07. Bars are labeled with impairment classifications.

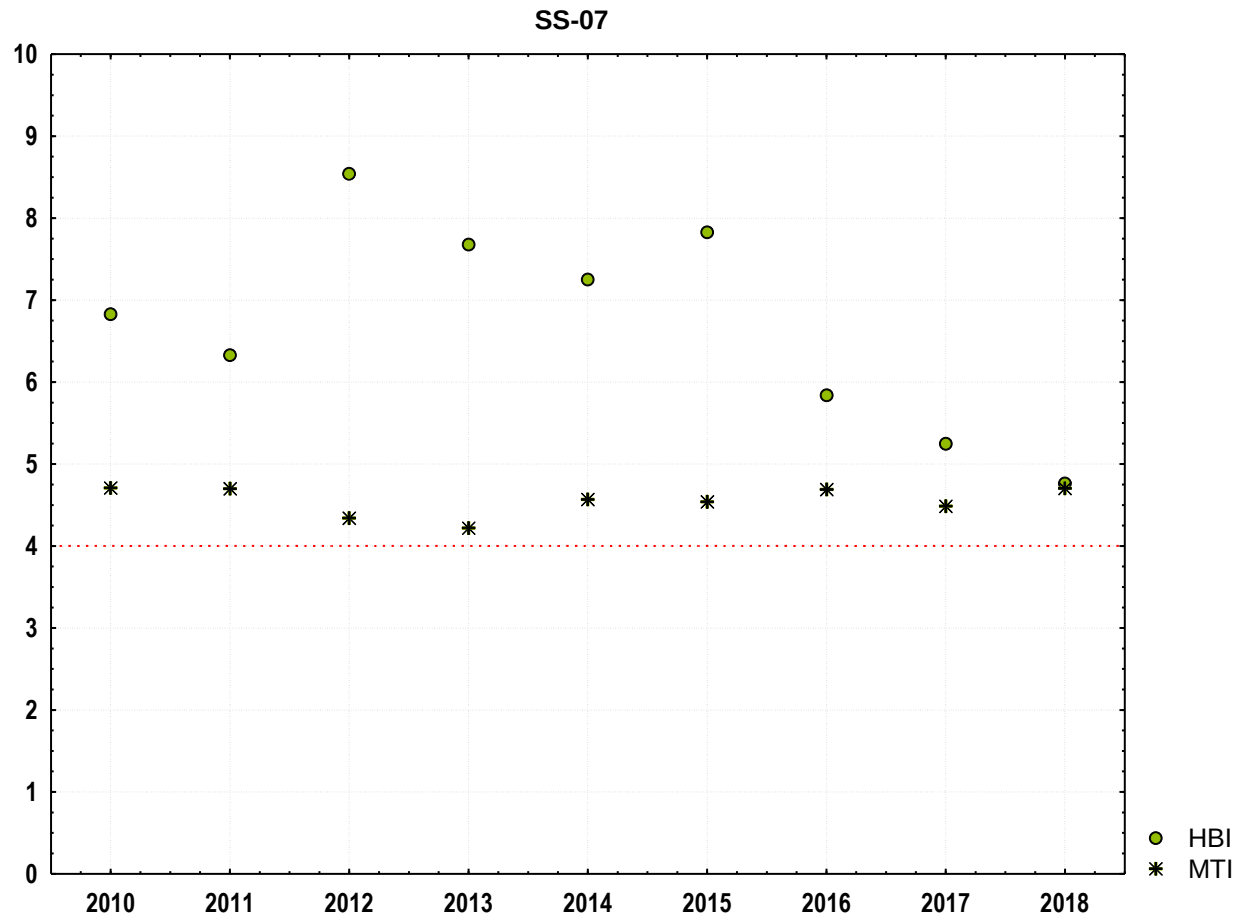

Figure 5-11. Hilsenhoff Biotic Index (HBI) and metals tolerance index (MTI) values: comparison among years for Site SS-07. The red dashed line represents the "no impact" threshold for both metrics established by McGuire for the Clark Fork River basin.

5.3.3.5 SS-08: Silver Bow Creek at Rocker

5.3.3.5.1 Comparisons among Years

Severe impairment was indicated by the MVFP index at Site SS-08 in 2018 (Figure 5-12). This rating was a reduction from the moderate scores seen from 2014 through 2017. According to McGuire's guidance, the MTI indicated slight impairment from metals in 2018. The MTI varied between slight and no impairment in all other years. In most years the HBI indicated mild-to-moderate nutrient enrichment. HBI and MTI scores are graphed in Figure 5-13.

5.3.3.5.2 2018 Data

5.3.3.5.2.1 Water quality

Mayfly diversity was well below expectations: the ubiquitous *Baetis tricaudatus* complex (9.0 percent) was the only mayfly taxon collected. The HBI (4.92) was elevated over expectations. indicating an assemblage that was somewhat tolerant of organic pollution. The sample contained no pollution-sensitive taxa and a very high percentage of pollution-tolerant organisms (38.6 percent). *Cheumatopsyche* species (24.5 percent), the most abundant taxon in the sample, made up most of the pollution-tolerant animals. In addition, given the abundance of *Cheumatopsyche* and *Hydropsyche* (20.0 percent), collector-filterers were very abundant (56.1 percent) in the sample. These ecological characteristics suggested that water quality was impaired through nutrient enrichment. Sediments may have also been hypoxic at times because hemoglobin-bearing organisms (1.5 percent) were common. A few specimens (4) of the flatworm class Trepaxonemata were collected suggesting that ground water was entering this reach. The MTI (4.69) exceeded the impairment threshold, consequently contamination by metals may have occurred in at Site SS-08.

5.3.3.5.2.2 Thermal condition

No cold-stenotherm taxa were collected at this site and warm water-loving taxa (*Stagnicola* species, 1.1 percent; *Oecetis* species, 2.6 percent; leeches in the genus *Erpobdella,* 0.2 percent) were common. The temperature preference of the assemblage was 16.5 C.

5.3.3.5.2.3 Sediment deposition

Eight caddisfly taxa (7 associated with stony sediments), many of which were abundant or common, along with 11 "clinger" taxa, were collected. The FSBI-2000 (3.84) indicated an assemblage that was moderately tolerant of the presence of fine sediments. However, little evidence was provided for the deposition of fine sediments on the stream bottom by the FSBI-2012 score of 25. These results suggested that slight hinderance of the colonization of the stony stream bottom by fine sediment could not be ruled out here.

5.3.3.5.2.4 Habitat diversity and integrity

No stonefly taxa and only 31 total taxa were found in this sample, consequently, instream and reach-scale habitats might be disturbed, although poor water quality cannot be ruled out as the cause. Although only two long-lived taxa were collected, the elmid beetle *Optioservus* species (9.6

percent) and the caddisfly *Brachycentrus occidentalis* (9.0 percent) were both abundant. Catastrophes such as toxic pollutants, dewatering, scouring sediment pulses, or thermal extremes can probably be ruled out. The functional composition of the assemblage was dominated by collector-filterers (56.1 percent) followed by collector-gatherers (22.8 percent). Scrapers (11.1 percent) were also well represented, but shredders (0.8 percent) were rare. These results suggested that the energy flow was dominated by fine particulate organic matter and that autochthonous algal production was also important. The lack of shredders suggested that leaf fall from the riparian zone was reduced or that such material was not retained in the reach.

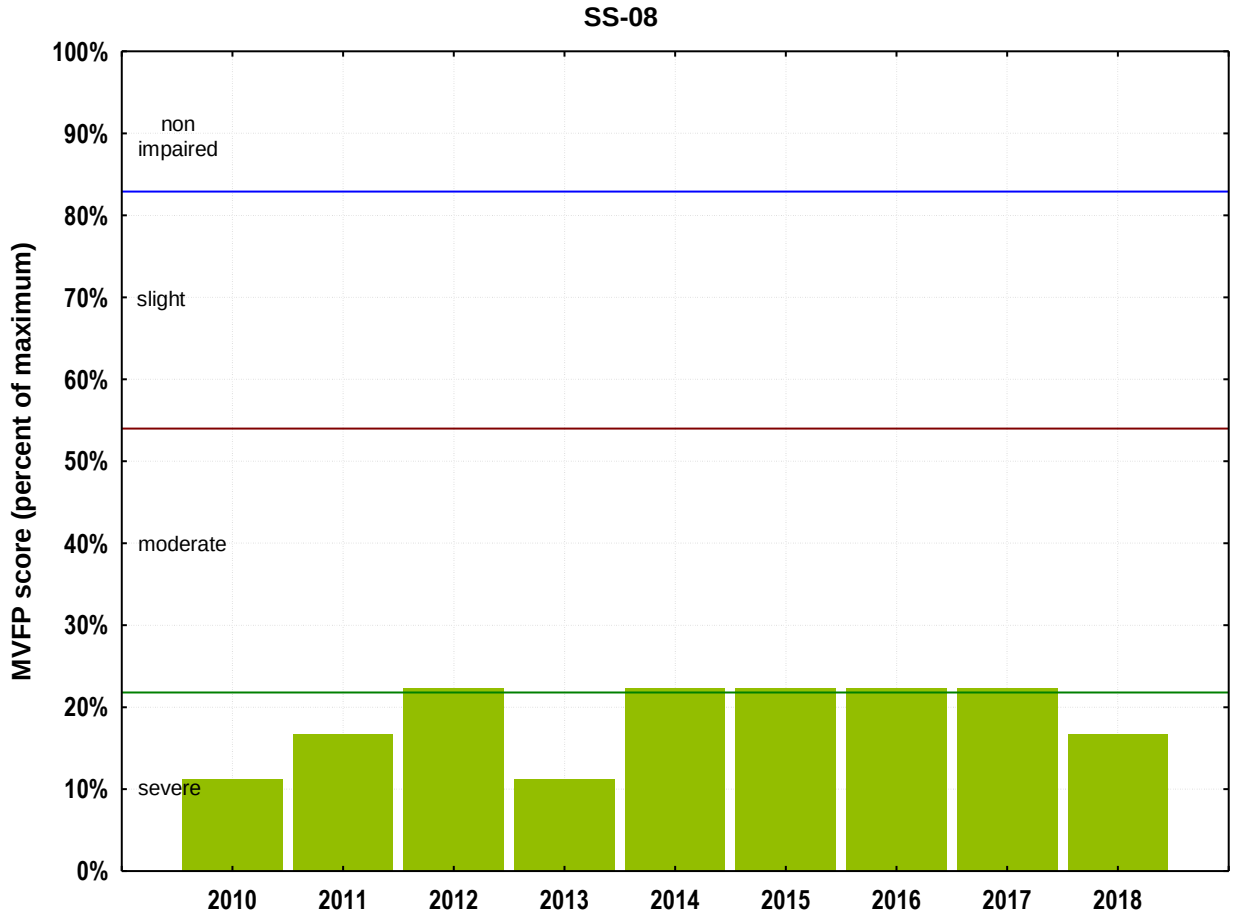

Figure 5-12. Montana Valley and Foothill Prairies (MVFP) bioassessment scores: comparison among years for Site SS-08 Bars are labeled with impairment classifications.

Figure 5-13. Hilsenhoff Biotic Index (HBI) and metals tolerance index (MTI) values: comparison among years for Site SS-08. The red dashed line represents the "no impact" threshold for both metrics established by McGuire for the Clark Fork River basin.

5.3.3.6 SS-10A: Silver Bow Creek above Sand Creek

5.3.3.6.1 Comparisons among Years

Moderate impairment was indicated by the MVFP bioassessment score in 2018. From 2010 to 2018 MVFP scores have indicated moderate impairment six times and severe impairment three times (Figure 5-14). The MTI indicated slight impairment in 2018 according to McGuire's guidance. MTI values in previous years varied between slight and no impairment (Figure 5-15). Although the HBI indicated moderate-to-severe nutrient enrichment from 2010 to 2017, mild enrichment was indicated in 2018 (Figure 5-15).

5.3.3.6.2 2018 Data

5.3.3.6.2.1 Water quality

The composition of the fauna suggested that water quality was impaired at Site SS-10A in 2018. *Baetis tricaudatus* complex (8.6 percent) was the only mayfly taxon reported from this location. The HBI (4.42) was elevated and the percentage of collector-filterers (65.7 percent) was extremely high; the filtering caddisflies *Hydropsyche* species (20.9 percent) and *Cheumatopsyche* species (20.3 percent) were the two most abundant taxa. Pollution-tolerant organisms (30.1 percent) were a large component of the assemblage and no pollution-sensitive taxa were found here. Given these characteristics water quality appeared to be impaired and nutrient enrichment probably played a role in that impairment. In addition, hemoglobin-bearing organisms (2.4 percent) were somewhat common, raising the possibility of hypoxic sediments. The MTI of 4.45 indicated the possibility of metals contamination at the site. Like several sites, a few flatworms in the class Trepaxonemata (5, 1.0 percent) were reported from the sample suggesting that ground water may be entering and influencing the composition of the invertebrate assemblage in this reach.

5.3.3.6.2.2 Thermal condition

Like all but one site in 2018, no cold-stenotherm taxa were reported from this site. The warm-water preferring caddisfly *Oecetis* species (1.0 percent) was present. The temperature preference of the assemblage was 17.1 C.

5.3.3.6.2.3 Sediment deposition

Caddisfly taxa richness (7, six associated with stony sediments) and "clinger" taxa richness (13) were slightly lower than expectations for a low order stream in the Middle Rockies ecoregion. All but one of the six caddisfly taxa associated with stony sediments were abundant or common (caddisflies made up 64.9 percent of the fauna). The FSBI-2000 of 4.23 suggested a moderately sediment-tolerant assemblage. The FSBI-2012 (10) provided little evidence of fine sediment deposition in this reach. Consequently, the data suggested that slight inhibition of invertebrate colonization of the stony stream bottom could not be ruled out at Site SS-10A.

5.3.3.6.2.4 Habitat diversity and integrity

As with many of the other sites, stoneflies were absent and overall taxa richness (30) was low, suggesting disturbed instream and reach-scale habitat features or poor water quality or both. However, 5 long-lived taxa were collected including the abundant caddisfly *Brachycentrus occidentalis* (17.3 percent) and the common beetle *Optioservus* species (2.6 percent). Consequently, catastrophes like periodic thermal extremes, scour, dewatering, or toxic pollutants were unlikely here in 2018. As mentioned earlier, collector-filterers (65.4 percent) were the most common functional group. Collector-gatherers (14.5 percent) and scrapers (8.6 percent) were also well represented. However, shredders (0.2 percent) were underrepresented. Thus, both fine particulate matter and autochthonous algal production appeared to be important to the energy flow in this reach, whereas coarse particulate organic matter was either rarely deposited in the reach, or if deposited, was not retained.

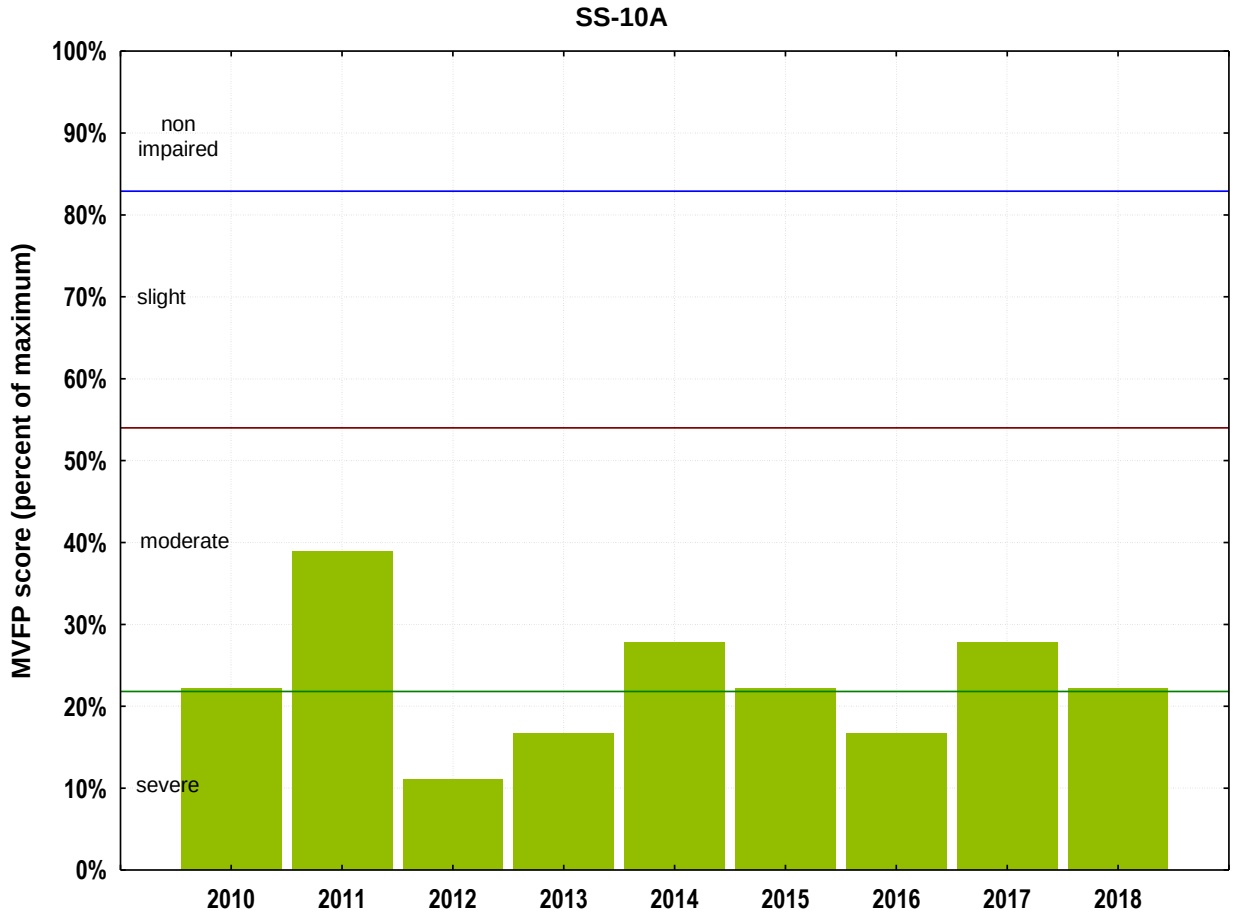

Figure 5-14. Montana Valley and Foothill Prairies (MVFP) bioassessment scores: comparison among years for Site SS-10A. Bars are labeled with impairment classifications.

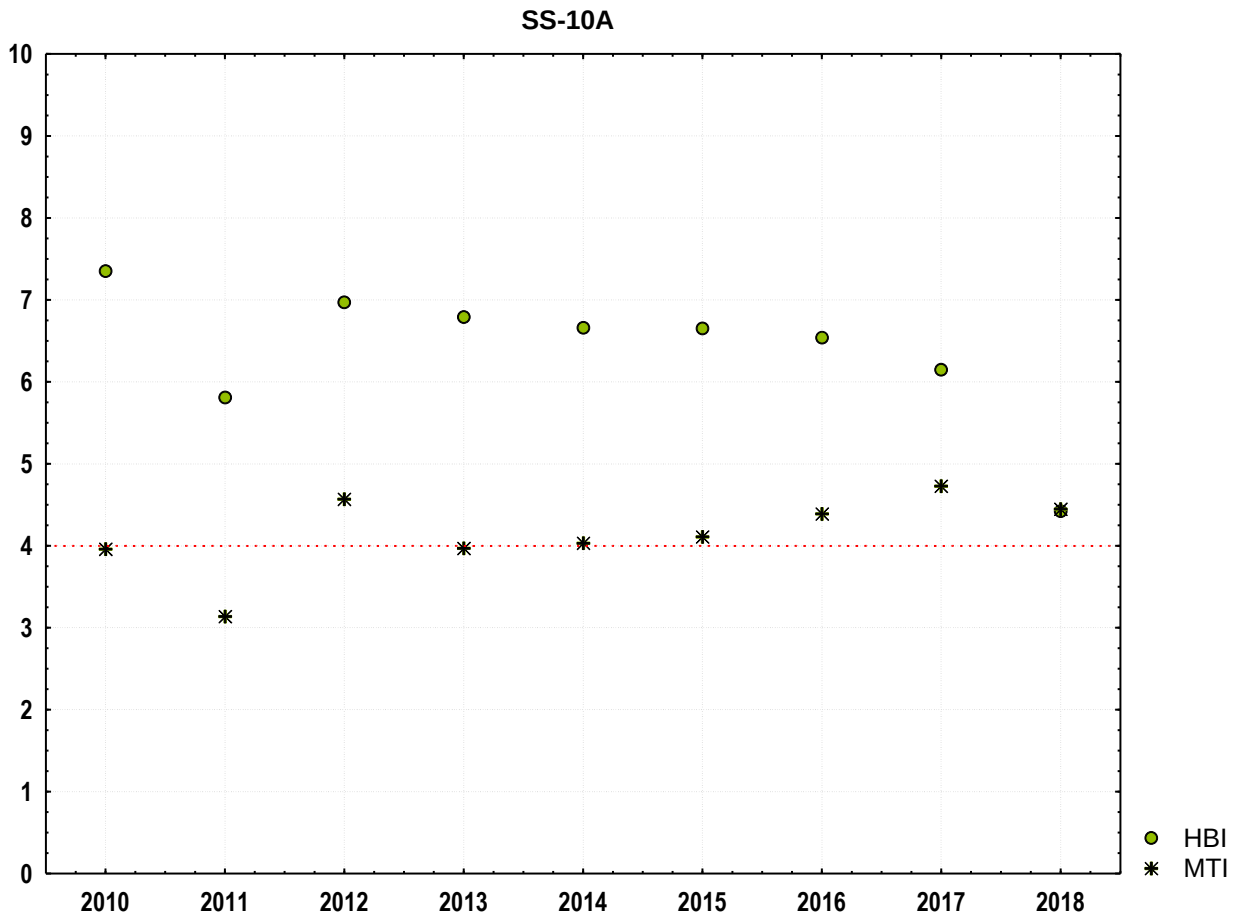

Figure 5-15. Hilsenhoff Biotic Index (HBI) and metals tolerance index (MTI) values: comparison among years for Site SS-10A. The red dashed line represents the "no impact" threshold for both metrics established by McGuire for the Clark Fork River basin.

5.3.3.7 SS-11C: Silver Bow Creek above Browns Gulch

5.3.3.7.1 Comparisons among Years

The MVFP bioassessment score indicated moderate impairment (Figure 5-16) as it had in 5 of eight of the previous years. Severe impairment was indicated in 2011, 2014 and 2017. The HBI indicated mild nutrient enrichment in 2018, similar to the mild-to-moderate nutrient enrichment detected since 2010 (Figure 5-17). According to McGuire's guidance, the MTI was slightly higher than the threshold for impairment in 2018 and it vacillated between slightly above and below that threshold since 2010 (Figure 5-17).

5.3.3.7.2 2018 Data

5.3.3.7.2.1 Water quality

The characteristics of the invertebrate fauna suggested that water quality was impaired, and that nutrient enrichment played a role in the impairment. Like many other sites visited in 2018, *Baetis tricaudatus* complex (10.9 percent) was the only mayfly taxon reported from this sample. The HBI value (4.82) suggested slight impairment as the result of nutrient enrichment. Sediment hypoxia was probably likely here as well because hemoglobin-bearing organisms (4.7 percent, mainly the midge *Microtendipes* species, (4.4 percent) were common. No pollution-sensitive taxa were collected. Pollution-tolerant organisms (24.2 percent) were a large component of the fauna, mainly due to the abundance of the caddisfly *Helicopsyche* species (11.1 percent) and the elmid beetle *Optioservus* species (6.7 percent). Collector-filterers (38.7 percent), including the filtering caddisfly *Brachycentrus occidentalis* (18.0 percent, the most abundant organism in the sample), sphaeriid clams (6.6 percent), blackflies (*Simulium* species, 4.2 percent), and *Microtendipes*, were extremely abundant. The MTI (4.09) provided only slight evidence for metals contamination.

5.3.3.7.2.2 Thermal condition

Several warm water-loving taxa were collected (e.g., *Helicopsyche* species, 11.1 percent; the leech *Theromyzon* species; 0.2 percent) and no cold water-loving taxa were reported in this sample. The temperature preference of the assemblage was 17.0 C.

5.3.3.7.2.3 Sediment deposition

An FSBI-2000 of 4.66 suggested that the assemblage was moderately sediment-tolerant and the FSBI-2012 (10) provided no additional evidence for the impact of fine sediment on the biota. Eight caddisfly and 11 "clinger" taxa were found. Given these data it appeared that the effects of fine sediment on the assemblage should not be dismissed here.

5.3.3.7.2.4 Habitat diversity and integrity

The sample yielded only 28 taxa, which may have been an indication of impaired water quality, disrupted habitats, or both. Like many other sites sampled in 2018, stoneflies were again absent suggesting that reach-scale disturbances such as unstable streambanks, loss of riparian function, or channel alteration may have occurred. Only three long-lived taxa were counted: *B. occidentalis* and the elmid beetle *Optioservus* species, which were both abundant, and the elmid *Zaitzevia*

species (0.4 percent), which was rare. Scour, dewatering, toxic pollutants, thermal extremes or other severe events that would prevent the completion of long-life cycles were unlikely here. Collector-filterers (38.7 percent), collector-gatherers (27.3 percent) and scrapers (18.6 percent) dominated the functional composition of the assemblage, which suggested that organic material as fine particulates, bacteria in suspension and deposited on the stream bottom, as well as algal production were important energy sources in the reach. However, few shredders (1.6 percent) were collected. Consequently, it appears that litter fall from riparian zones contributed little to the food web.

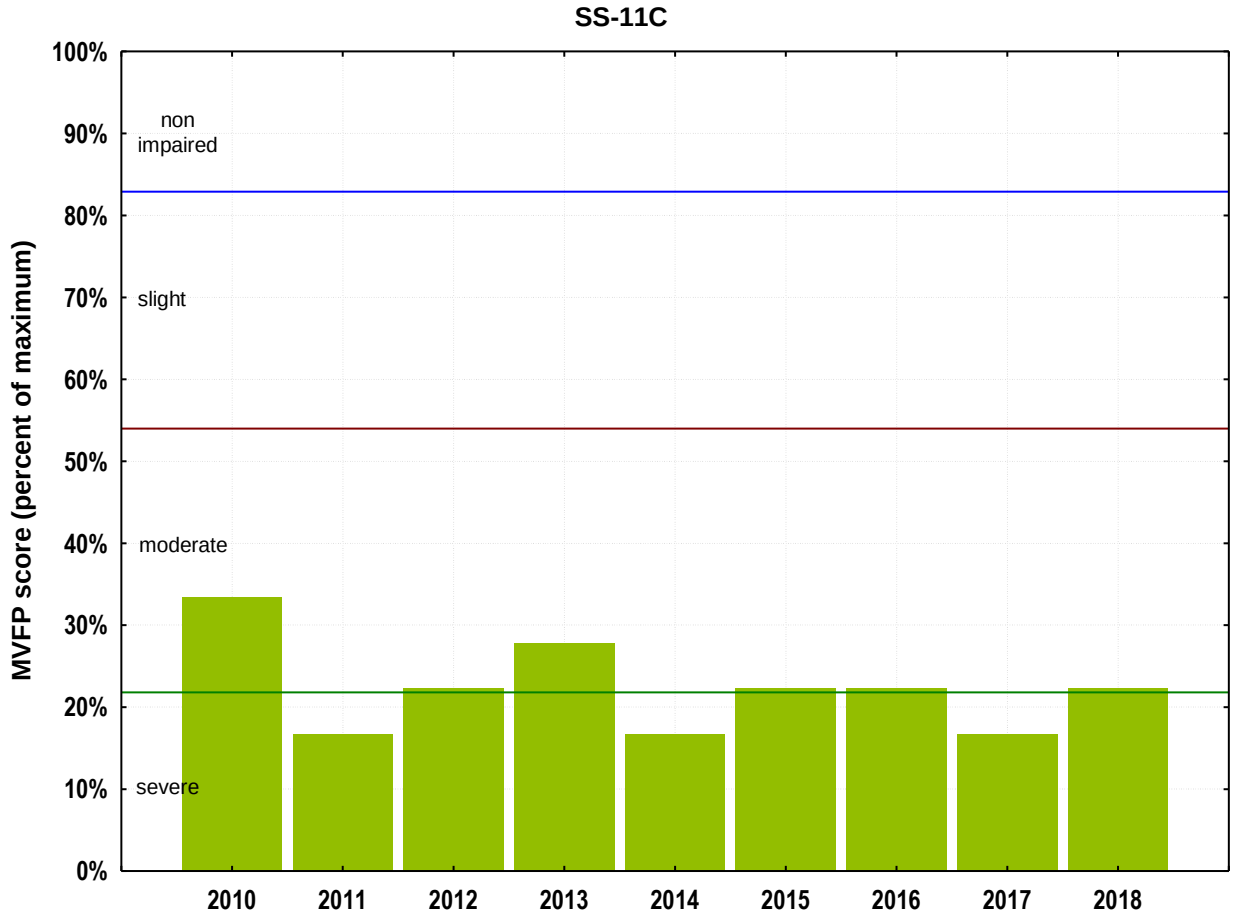

Figure 5-16. Montana Valley and Foothill Prairies (MVFP) bioassessment scores: comparison among years for Site SS-11C. Bars are labeled with impairment classifications.

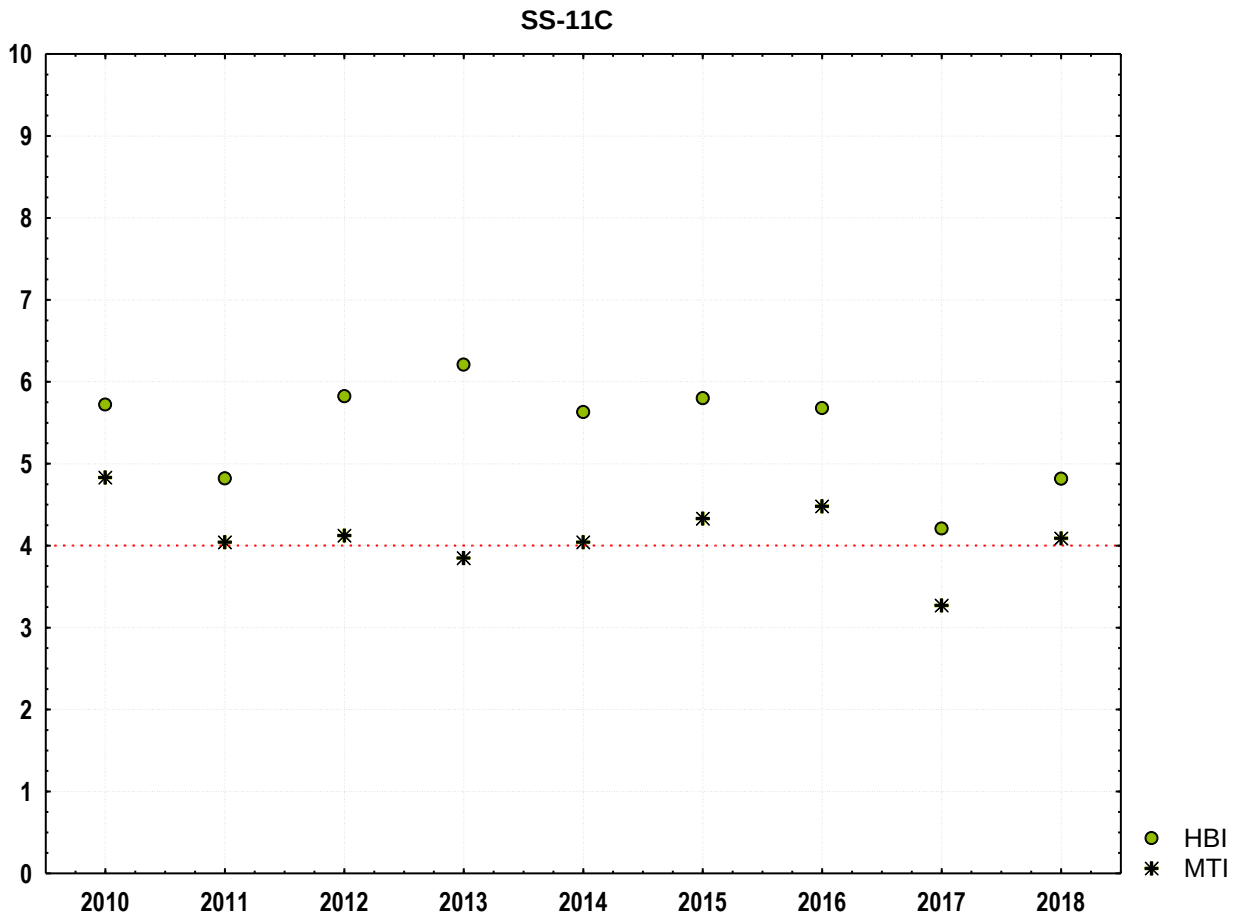

Figure 5-17. Hilsenhoff Biotic Index (HBI) and metals tolerance index (MTI) values: comparison among years for Site SS-11C. The red dashed line represents the "no impact" threshold for both metrics established by McGuire for the Clark Fork River basin.

5.3.3.8 SS-11D: Silver Bow Creek below Browns Gulch

5.3.3.8.1 Comparisons among Years

Like scores in most other years, the MVFP index score indicated moderate impairment at Site SS-11D in 2018 (Figure 5-18). The MTI did not indicate contamination by metals in 2018 using McGuire's guidance (Figure 5-19). Indeed, the MTI has fluctuated between slight and no evidence for metals contamination since 2010. The HBI indicated mild nutrient enrichment in 2018 and has vacillated between mild and moderate nutrient enrichment since 2010 (Figure 5-19).

5.3.3.8.2 2018 Data

5.3.3.8.2.1 Water quality

Baetis tricaudatus complex (5.1 percent), *Iswaeon* species (0.6 percent) and an unidentified genus in the family Leptophlebiidae (0.2 percent) were the only mayfly taxa collected at this site in 2018. The HBI was 4.52 indicating an assemblage that was somewhat tolerant of organic pollution. Similar to Site SS-11C, hemoglobin-bearing organisms (4.4 percent) were common and were represented primarily by the midge *Microtendipes* species (3.7 percent). These results suggested that water quality was impaired in part through nutrient enrichment and that hypoxic sediments might have been a problem as well. The sample contained no pollution-sensitive taxa and a very high percentage of pollution-tolerant organisms (43.9 percent). In addition, a few specimens of flatworms in the order Trepaxonemata (0.7 percent) were reported, which may indicate that ground water had an influence on surface waters at this site. There appeared to be no evidence of metals contamination as the MTI (3.98) was below the impairment threshold.

5.3.3.8.2.2 Thermal condition

No cold-stenotherm and several warm-water loving taxa were collected including the caddisfly *Helicopsyche* species (20.3 percent, the most abundant organism in the sample) and leeches *Erpobdella* species (1 specimen) and *Theromyzon* species (5 specimens). The temperature preference of the assemblage was 16.6 C.

5.3.3.8.2.3 Sediment deposition

The caddisflies were represented by nine taxa (8 associated with stony sediments) and the "clingers" were represented by 14 taxa. The FSBI-2000 of 4.12 indicated a fauna that was moderately sediment-tolerant; however, the FSBI-2012 (10) added no support to this contention. Thus, most characteristics suggested that slight limitation of invertebrate colonization by the deposition of fine sediment should not be dismissed at Site SS-11D.

5.3.3.8.2.4 Habitat diversity and integrity

Instream habitats appeared to be diverse and intact at Site SS-11D as overall taxa richness was 44. Three stonefly taxa were recorded: *Isoperla* species (2 specimens, 0.4 percent), *Skwala* species (2 specimens, 0.4 percent), and unidentified Chloroperlidae (6 specimens, 1.1 percent). Although only one other site had more stonefly taxa in 2018 than Site SS-11D, the diversity of stoneflies was still somewhat below expectations, suggesting that reach-scale habitat disruption

cannot be ruled out here. Four non-pioneer semivoltine taxa were present. The caddisfly *Brachycentrus occidentalis* (8.6 percent) and the elmid beetle *Optioservus* species (14.1 percent) were both abundant, whereas the elmid *Zaitzevia* species (1.3 percent) and dragonflies in the family Gomphidae (0.9 percent) were common. Given the abundances of these taxa, catastrophes such as periodic scour, dewatering, thermal stress, or toxic pollutants were probably unlikely. Interestingly, scrapers (36.2 percent) dominated the functional-feeding groups in part because the grazing caddisfly *Helicopsyche* species was the dominant organism in the sample. Thus, algal films were probably important autochthonous energy sources in this reach and may have indicated an open canopy. Fine particulate organic matter was also a major part of the food web as collector-filterers (20.5 percent) and collector-gatherers (20.7 percent) were also very abundant. Although shredders (4.9 percent) were not extremely abundant, their presence suggested that large organic materials such as leaves and woody debris from riparian sources were significant in the food web as well.

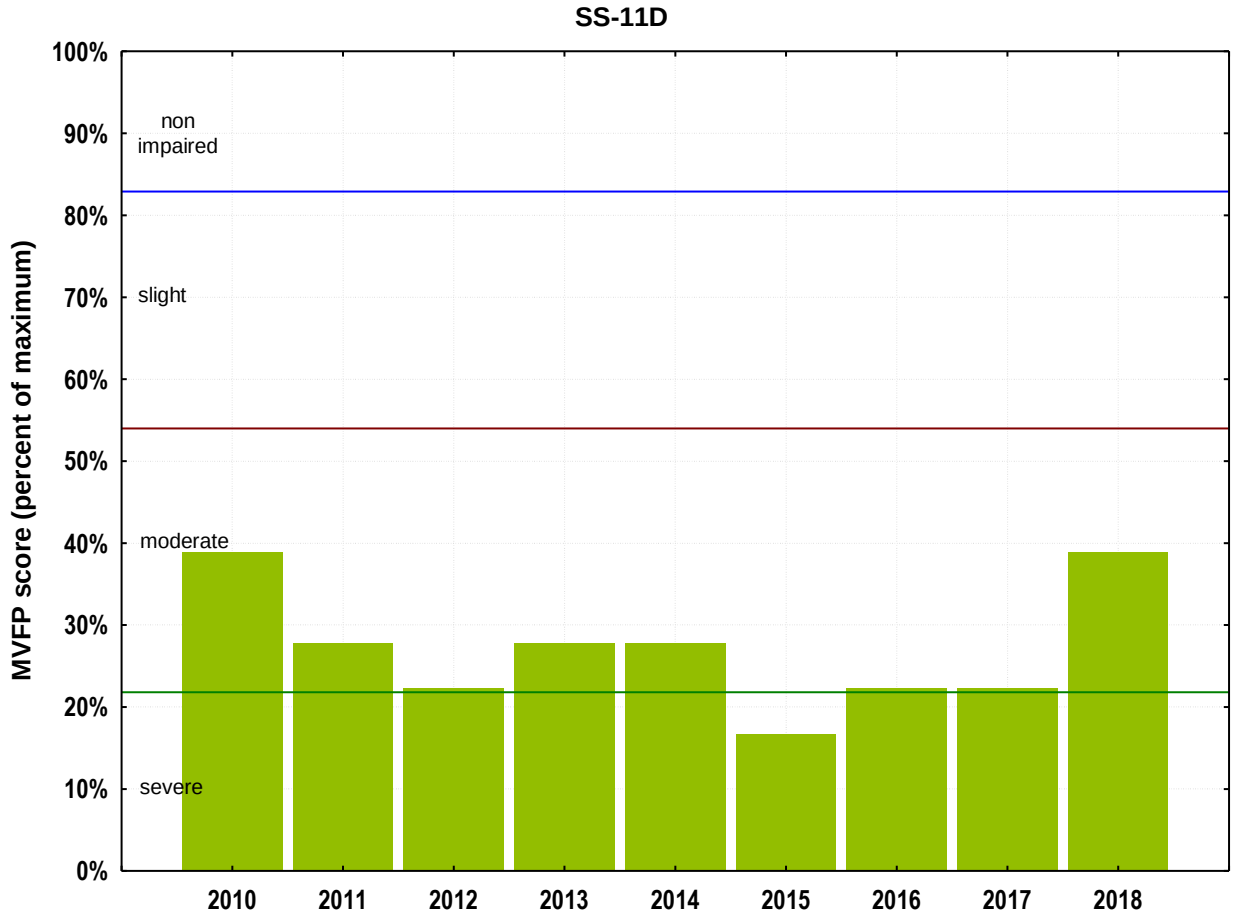

Figure 5-18. Montana Valley and Foothill Prairies (MVFP) bioassessment scores: comparison among years for Site SS-11D. Bars are labeled with impairment classifications.

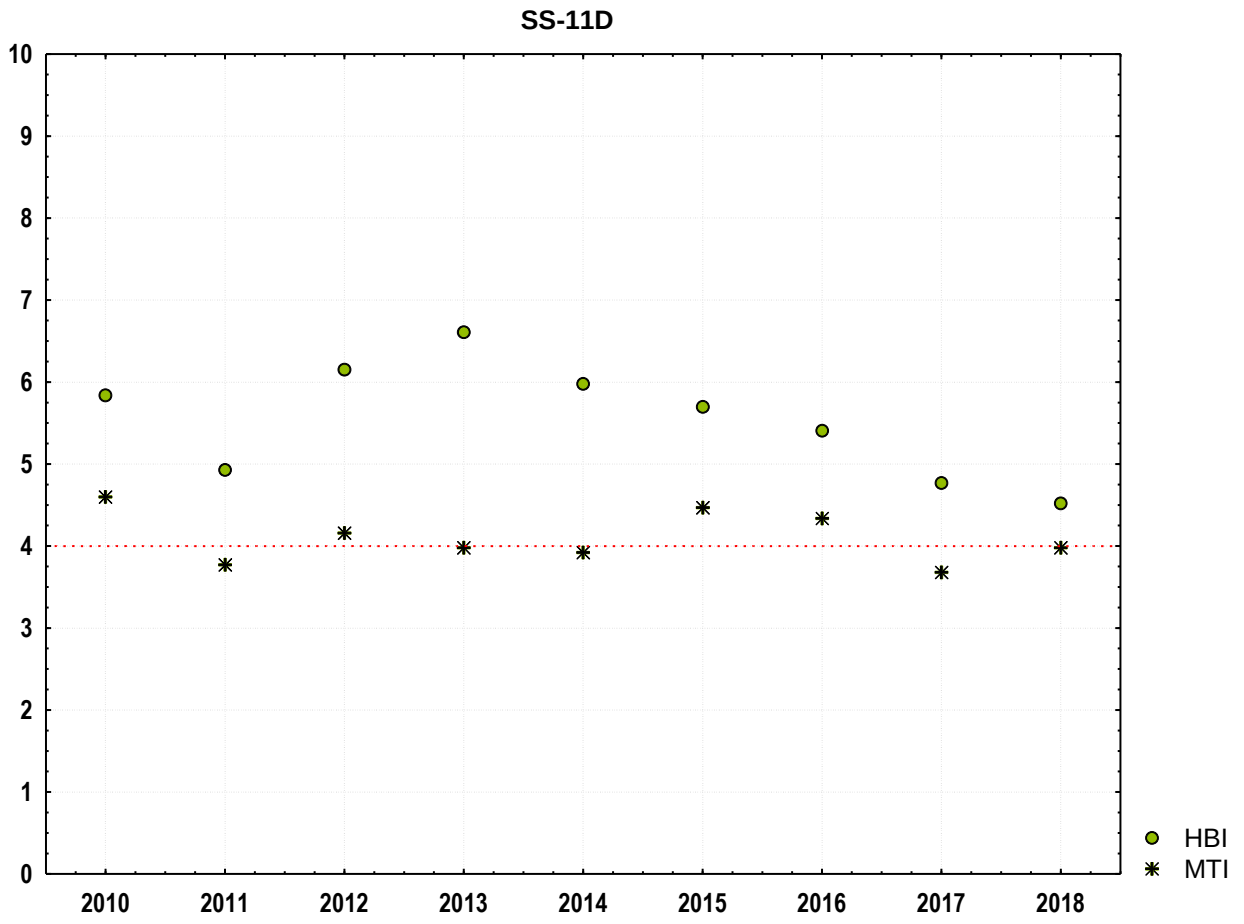

Figure 5-19. Hilsenhoff Biotic Index (HBI) and metals tolerance index (MTI) values: comparison among years for Site SS-11D. The red dashed line represents the "no impact" threshold for both metrics established by McGuire for the Clark Fork River basin.

5.3.3.9 SS-13: Silver Bow Creek in Reach L

5.3.3.9.1 Comparisons among Years

The MVFP bioassessment index score rebounded from a low in 2017, which resulted in a severely impaired rating, to again rate the site as moderately impaired in 2018 (Figure 5-20). According to McGuire's guidance, the MTI provided no evidence of impairment from metals in 2018, an impairment classification that was similar to 2014 and 2017 (Figure 5-21). The HBI reversed the steady downward trend in values seen between 2013 and 2017: slight nutrient enrichment was indicated in 2018 (Figure 5-21).

5.3.3.9.2 2018 Data

5.3.3.9.2.1 Water quality

Most of the ecological characteristics that were examined suggested that water quality was impaired in this reach. Four mayfly taxa were found in this sample, but only *Baetis tricaudatus* complex (1.5 percent) was common. The HBI (5.09), which indicated that organic pollution influenced the fauna in this reach, was the highest of any of the sites examined in 2018. Collector-filterers (49.0 percent), mainly the midge *Microtendipes* species (26.0 percent, the dominant organism in the sample) and the caddisfly *Brachycentrus occidentalis* (14.5 percent), dominated the functional mix. These results suggested that water quality impairment was due to nutrient enrichment. In addition, hemoglobin-bearing organisms (26.7 percent, mostly the midge *Microtendipes* species) were very abundant: sediments may have been hypoxic. No sensitive taxa were counted and pollution-tolerant organisms (21.7 percent) *were* a very large component of the assemblage. The MTI (3.95) indicated no impact from metals contamination.

5.3.3.9.2.2 Thermal condition

The calculated thermal preference of the assemblage was 18.4 C and no cold-loving taxa were collected from this site. The high relative abundance of the scraping caddisfly *Helicopsyche* species (10.9 percent) and the presence of the leeches *Erpobdella* species (5 animals) and *Theromyzon* species (1 animal) also suggested warm water temperatures.

5.3.3.9.2.3 Sediment deposition

Seven caddisfly taxa were found in this sample. *Brachycentrus occidentalis* and *Helicopsyche* species were very abundant and *Hydropsyche* species (1.3 percent), *Nectopsyche* species (1.5 percent), and *Oecetis* species (1.1 percent) were common. The "clingers" were represented by 12 taxa. The FSBI-2000 (4.73) indicated a moderately sediment-tolerant fauna. The FSBI-2012 was 5. Thus, slight inhibition of invertebrate colonization of stony substrates by fine sediment could not be ruled out.

5.3.3.9.2.4 Habitat diversity and integrity

Overall diversity (taxa richness = 31) was somewhat lower than expected and may have been associated with water quality impairment or limited instream habitats, or both. *Skwala* species (2 specimens, 0.4 percent of the fauna) was the only stonefly species collected, which may have

also reflected poor water quality or disrupted reach-scale habitat features. Four semivoltine taxa were reported: the elmid *Dubiraphia* species (0.2 percent) and gomphid odonates (0.6 percent) were rare, whereas *Optioservus* species (6.2 percent) and *Brachycentrus occidentalis* were abundant. Catastrophes that disrupt the life cycles of long-lived organisms were rare enough that semivoltine species were able to complete their life cycles. Collector-filterers (49.0 percent) followed by scrapers (17.5 percent) and collector-gatherers (15.1 percent) were the most abundant functional groups indicating the importance of fine particulate organic matter and instream algal production to the energy flow in this system. Shredders (2.6 percent) were underrepresented, perhaps reflecting a lack of riparian inputs to the stream, or the lack of retention of such material.

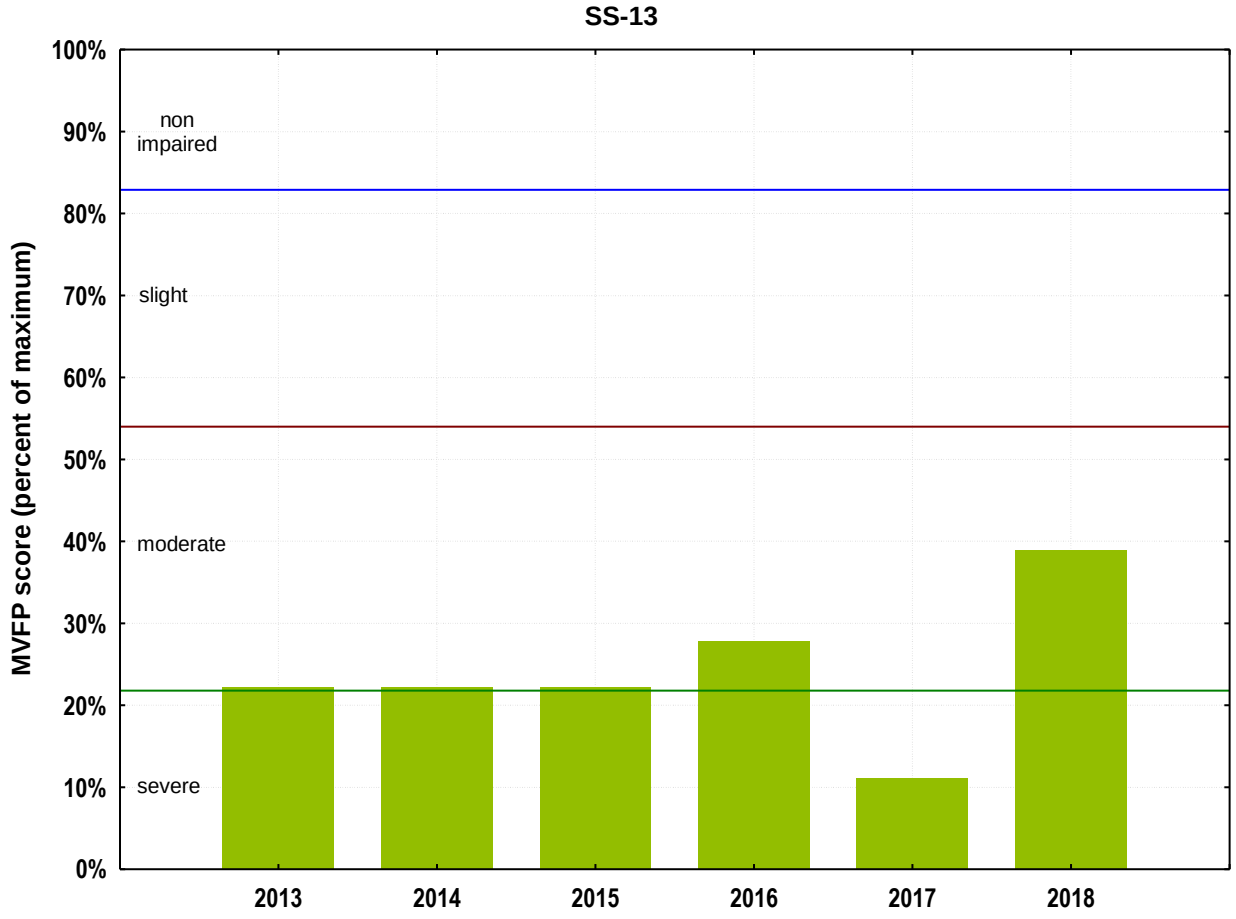

Figure 5-20. Montana Valley and Foothill Prairies (MVFP) bioassessment scores: comparison among years for Site SS-13. Bars are labeled with impairment classifications.

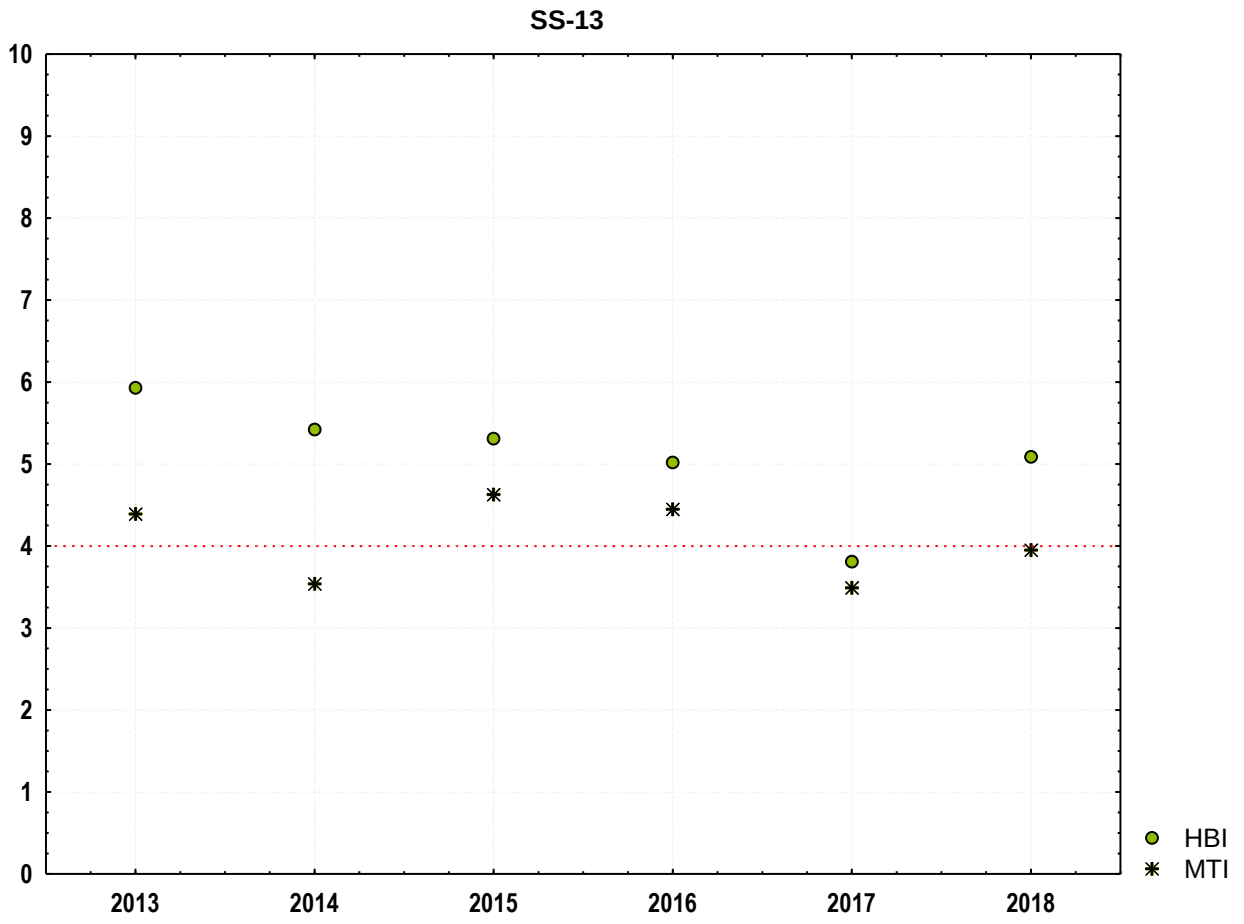

Figure 5-21. Hilsenhoff Biotic Index (HBI) and metals tolerance index (MTI) values: comparison among years for Site SS-13. The red dashed line represents the "no impact" threshold for both metrics established by McGuire for the Clark Fork River basin.

5.3.3.10 SS-14D: Silver Bow Creek at Miles Crossing

5.3.3.10.1 Comparisons among Years

Since sampling began in 2010, MVFP scores have consistently indicated moderate impairment at Site SS-14D, a trend that continued in 2018 (Figure 5-22). Based on McGuire's guidance, the MTI in 2018 continued a trend of no metals contamination that began in 2013 (Figure 5-23). The HBI indicated very slight impact from nutrient enrichment in 2018, which followed two years of no impact and several years of mild-to-moderate enrichment (2010-2015) (Figure 5-23).

5.3.3.10.2 2018 Data

5.3.3.10.2.1 Water quality

In 2018, water quality appeared to be impaired at Site SS-14D. The HBI (4.15) was elevated above expectations and only three mayfly taxa were found in the sample. *Baetis tricaudatus* complex (3.1 percent) was common, but *Iswaeon* species (0.2 percent) and *Tricorythodes* species (0.2 percent) were rare. Hemoglobin-bearing organisms (14.5 percent, mostly the midge *Microtendipes* species (14.2 percent)) were very abundant and collector-filterers (50.7 percent, mainly *Brachycentrus occidentalis*, 29.5 percent, the most abundant organism in the sample, and *Microtendipes*) dominated the functional mix. Pollution-tolerant organisms (28.3 percent) were a large component of the assemblage and no pollution-sensitive taxa were reported. Impacts to water quality through nutrient enrichment seemed likely here. In addition, sediments may have had times of low oxygen concentration given the number of hemoglobin-bearing organisms that were collected. The MTI (3.64) indicated no impact from metals contamination.

5.3.3.10.2.2 Thermal condition

No cold-stenotherms were found in the sample from this site. The temperature preference of the assemblage was 16.8 C. In addition, the warm-water loving caddisfly taxa *Helicopsyche* species (14.0 percent) and *Oecetis* species (2.1 percent) and the leech *Erpobdella* species (2 specimens) were collected.

5.3.3.10.2.3 Sediment deposition

Eight caddisfly taxa were present in the sample including the abundant *Brachycentrus occidentalis*, *Helicopsyche* species, *Oecetis* species, and *Hydropsyche* species (2.9 percent). In addition, 12 "clinger" taxa were collected. The FSBI-2000 (5.06) indicated a moderately sediment-tolerant assemblage and the FSBI-2012 was 15. Consequently, sediment deposition limiting invertebrate colonization of stony substrates cannot be ruled out in this reach.

5.3.3.10.2.4 Habitat diversity and integrity

As with many of the other sites, taxa richness (35) was below expectations. Stoneflies were rare: *Skwala* species (1.5 percent) was the only plecopteran collected. Thus, disturbed instream and reach-scale habitat features or poor water quality or both may have been indicated. Catastrophes were probably unlikely here as 4 long-lived taxa were collected, including the abundant caddisfly *B. occidentalis* (29.5 percent) and the abundant elmid beetle *Optioservus*

species (9.0 percent). Collector-filterers (50.7 percent) were the most abundant functional feeding group followed by scrapers (25.4 percent) and collector-gatherers (12.2 percent). These features of the feeding guild suggested that fine particulate organic matter and its associated bacteria and autochthonous algal production were important to the energy flow in this reach. Shredders (2.5 percent) were not well represented implying that coarse particulate organic matter was not deposited or retained on the stream bottom.

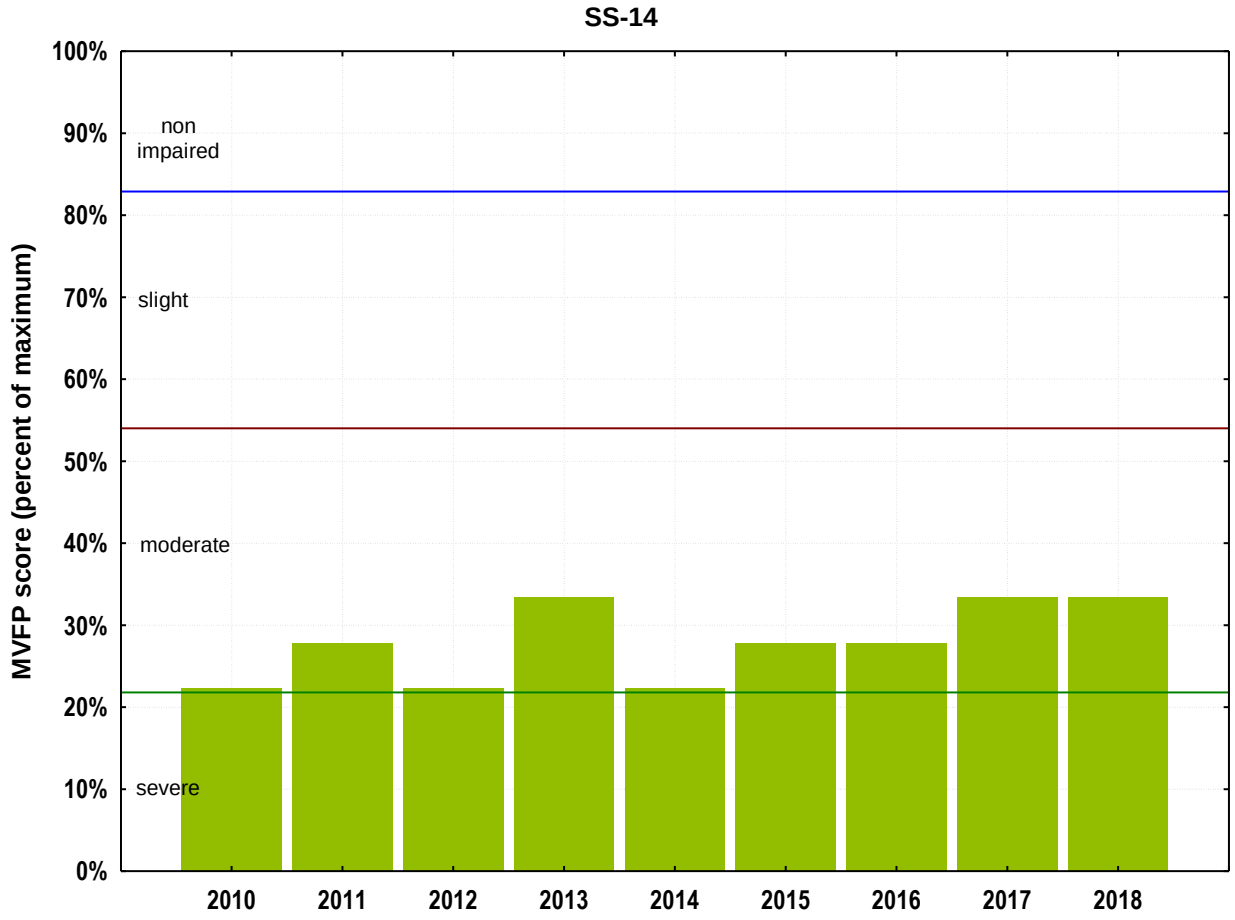

Figure 5-22. Montana Valley and Foothill Prairies (MVFP) bioassessment scores: comparison among years for Site SS-14D. Bars are labeled with impairment classifications.

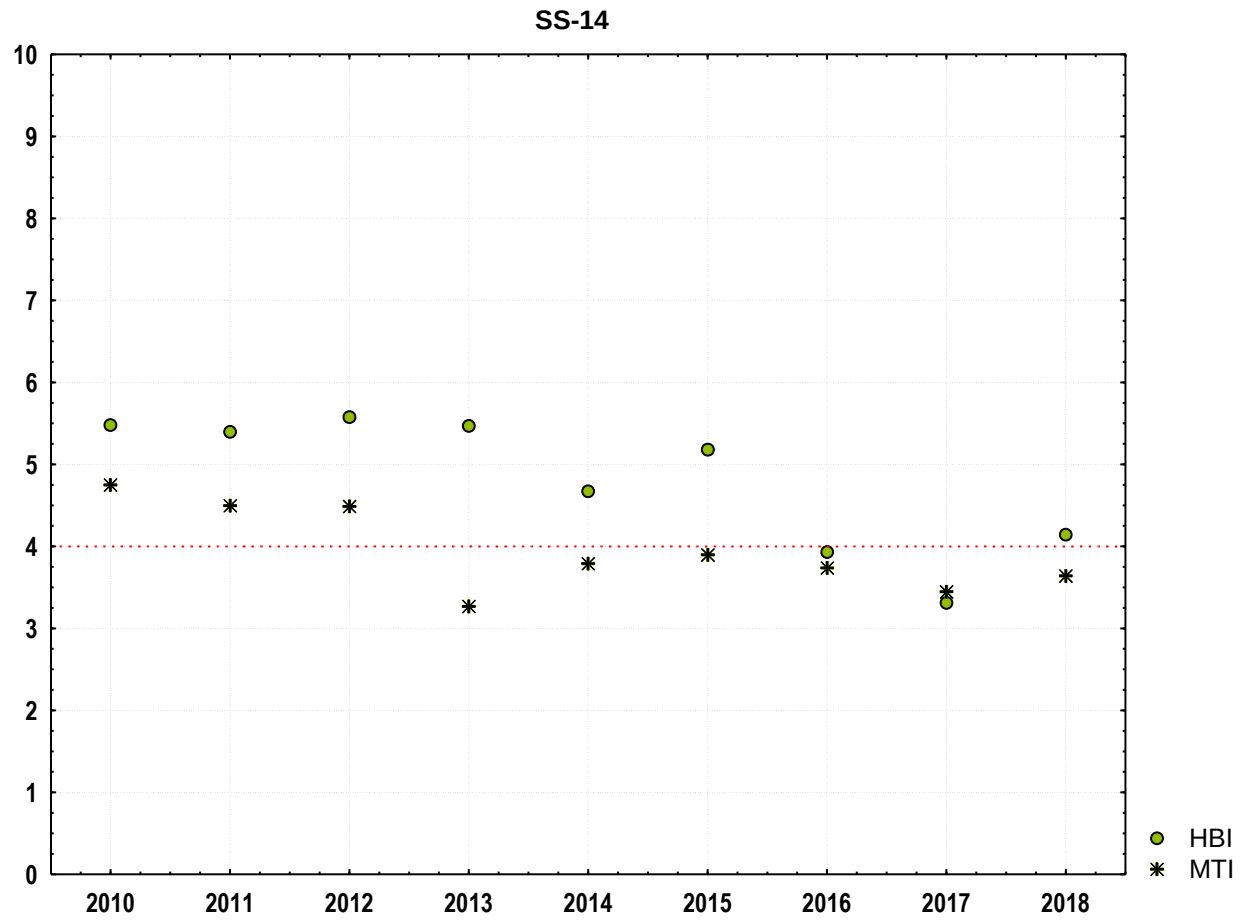

Figure 5-23. Hilsenhoff Biotic Index (HBI) and metals tolerance index (MTI) values: comparison among years for Site SS-14D. The red dashed line represents the "no impact" threshold for both metrics established by McGuire for the Clark Fork River basin.

5.3.3.11 SS-15A-2: Silver Bow Creek above German Gulch (Alternate Site)

5.3.3.11.1 Comparisons among Years

Site SS-15A was moved upstream into a remediated reach (Site SS-15A-2) in 2018 (see methods for discussion of the site change). MVFP scores and MTI and HBI scores from 2010 to 2017 at Site SS-15A and in 2018 at Site SS-15A-2 site are graphed in Figure 5-24 and Figure 5-25, respectively. Like Site SS-15A in most previous years, Site SS-15A-2 was moderately impaired in 2018, as measured by the MVFP bioassessment index. Following the score reduction that occurred in 2017 at Site SS-15A, the HBI at Site SS-15A-2 was lower in 2018 with the lowest value ever scored at these sites. According to McGuire's guidance, the MTI indicated no impairment from metals continuing an improvement that began in 2015 (Figure 5-25).

5.3.3.11.2 2018 Data

5.3.3.11.2.1 Water quality

As described above, Site SS-15A was abandoned, and replaced by Site SS-15A-2 in 2018 (see methods section for details). Indicators of water quality at the Silver Bow Creek site above German Gulch site gave mixed results in 2018. Only one mayfly taxon was found in this sample; however, it was abundant (*Baetis tricaudatus* complex; 9.7 percent). No pollution-sensitive taxa were collected and the relative abundance of pollution-tolerant organisms (8.5 percent) was somewhat above expectations. In addition, the relative abundance of collector-filterers (15.9 percent) was slightly above expectations. However, the HBI (2.53) provided no evidence for water quality impairment through organic pollution and no hemoglobin-bearing organisms were reported from this sample. The mixed results for water quality impairment suggested that slight impairment through nutrient enrichment cannot be dismissed at this site in spite of the low HBI. The MTI (2.60) was not indicative of metals pollution. In fact, the metals-intolerant caddisfly *Lepidostoma* species (48.8 percent) was the dominant animal in the assemblage.

5.3.3.11.2.2 Thermal condition

The temperature preference of the assemblage was 16.6 C. No cold-stenotherm taxa were collected, and a few warm-water preferring taxa were present (i.e., *Helicopsyche,* 1.9 percent; *Oecetis*, 1.0 percent).

5.3.3.11.2.3 Sediment deposition

Eleven "clinger" and six caddisfly taxa were collected at Site SS-15A-2. Four of the caddisfly taxa were abundant (i.e., *Lepidostoma* species, *Hydropsyche* species (6.8 percent), *Brachycentrus occidentalis* (5.9 percent), *Glossosoma* species (6.1 percent)). However, the FSBI-2000 value of 3.32 indicated a sediment-tolerant assemblage. The FSBI-2012 was 15. Thus, limitation of colonization of stony sediments by the deposition of fine sediments cannot be dismissed at Site SS-15A-2.

5.3.3.11.2.4 Habitat diversity and integrity

Taxa richness (26) was lower than expected thus, instream habitats may have been monotonous or disrupted. *Zapada cinctipes* (0.4 percent), *Isoperla* species (0.2 percent), and *Skwala* species (1.1 percent) were the three stonefly taxa recorded from this site. Although only one other site had stonefly diversity higher than Site SS-15A-2, richness here was still lower than expected: this may be related to disrupted reach-scale habitat features. Three long-lived taxa (*Brachycentrus occidentalis; Optioservus* species, 3.6 percent; *Zaitzevia* species, 0.2 percent) were counted, consequently catastrophic scour, thermal extremes, dewatering, or toxic pollutants probably did not stress the fauna here. Interestingly, shredders (49.2 percent) dominated the functional composition of the assemblage, because of the abundance of the shredding caddisfly *Lepidostoma*. Collector-filterers (15.9 percent), collector-gatherers (17.3 percent) and scrapers (11.8 percent) were also abundant. It seems likely that both allochthonous fine and coarse organic particulate matter, probably a result of algal decomposition in upstream reaches and litter-fall from stream side vegetation, were important energy sources here. It also seems likely that there was some contribution to the food web by autochthonous algal production.

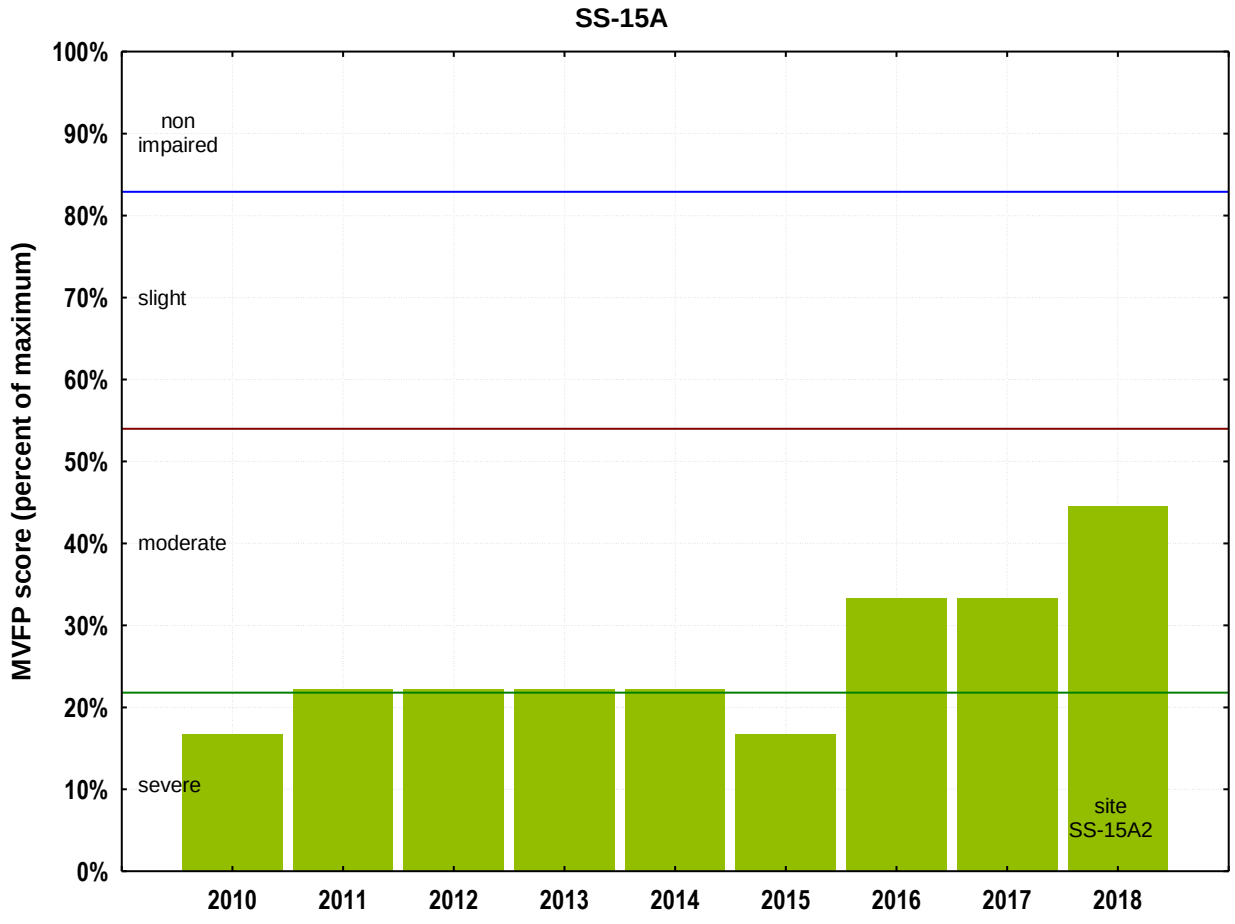

Figure 5-24. Montana Valley and Foothill Prairies (MVFP) bioassessment scores: comparison among years for Site SS-15A. Bars are labeled with impairment classifications.

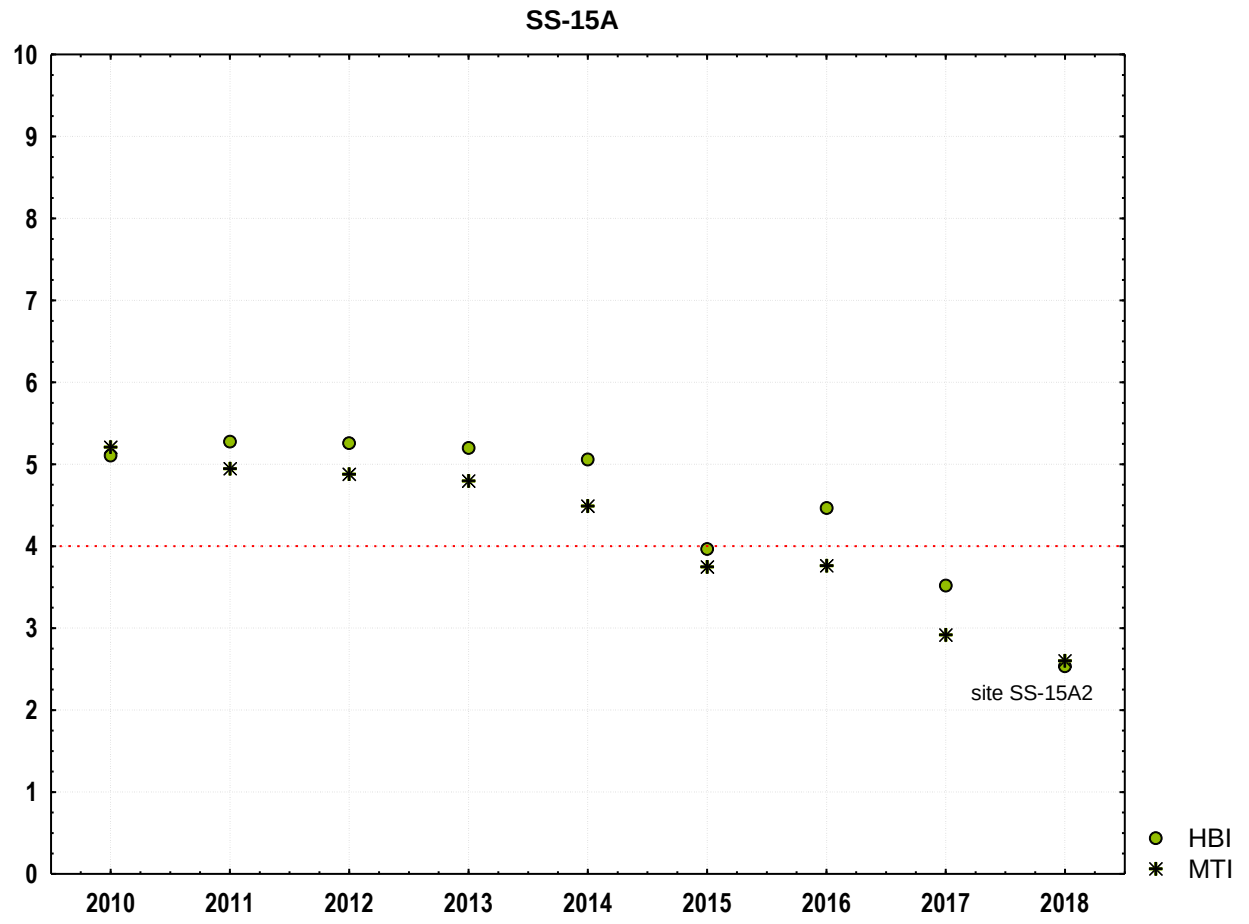

Figure 5-25. Hilsenhoff Biotic Index (HBI) and metals tolerance index (MTI) values: comparison among years for Site SS-15A. The red dashed line represents the "no impact" threshold for both metrics established by McGuire for the Clark Fork River basin.

5.3.3.12 SS-15B: Silver Bow Creek below German Gulch

5.3.3.12.1 Comparisons among Years

In 2018, the MVFP score showed moderate impairment at Site SS-15B. MVFP scores have varied over time at this site: slight impairment was indicated in two years, moderate impairment in six years and severe impairment in one year (Figure 5-26). Both the MTI (according to McGuire's guidance) and HBI indicated no impairment in 2018 (Figure 5-27). Both metrics continued trends of consistent improvement in recent years.

5.3.3.12.2 2018 Data

5.3.3.12.2.1 Water quality

Characteristics of the invertebrate fauna provided mixed results concerning water quality at this site. Of the 4 mayfly taxa reported from Site SS-15B, the ubiquitous *Baetis tricaudatus* complex (3.0 percent) was abundant, *Cinygmula* species (0.9 percent) was common and *Drunella* species (0.2 percent) and *Rhithrogena* species (0.2 percent) were rare. The HBI (2.50) indicated an assemblage that was probably not impacted by organic pollution and there were no hemoglobin-bearing organisms in the sample. However, the percentages of collector-filterers (31.2 percent), primarily made up of the caddisfly *Hydropsyche* species (27.0 percent, the most abundant animal in the collection), were above expectations. Pollution-tolerant organisms (5.8 percent) were slightly above expectations, but they did not overwhelm the composition of the assemblage. No pollution-sensitive taxa were collected. Given that no pollution sensitive taxa were collected, that mayfly diversity was slightly lower than expected, and that collector-filterers and pollution tolerant organisms made up significant percentages of the assemblage, slight water quality impairment cannot be ruled out. However, most indicators suggested that water quality was improved compared to upstream sites. A low MTI (2.97), high abundance of the caddisfly *Lepidostoma* species (25.7 percent), and the presence of the heptageniid mayflies *Cinygmula* and *Rhithrogena* suggested that metals contamination was not influential.

5.3.3.12.2.2 Thermal condition

No cold-loving taxa were reported; however, few warm-water loving organisms were found. The temperature preference calculated for this assemblage was 14.3 C, which was the second lowest calculated temperature preference in 2018.

5.3.3.12.2.3 Sediment deposition

Twenty "clinger" and nine caddisfly taxa were found in this sample. Some of the caddisfly taxa were very abundant (e.g., *Hydropysche*, *Lepidostoma*). The FSBI-2000 was 4.37 indicating a moderately sediment-tolerant assemblage. However, the FSBI-2012 was 110. Fine sediments are typically less than 30 percent of the stream bottom when sites have an FSBI-2012 score near this value. Consequently, it appeared likely that sediment deposition did not influence invertebrate colonization in this reach.

5.3.3.12.2.4 Habitat diversity and integrity

Both the perlid stonefly *Hesperoperla pacifica* (0.9 percent) and the nemourid *Zapada cinctipes* (1.5 percent) were collected and taxa richness (33) was lower than expected so streambanks may have been unstable, channel morphology may have been altered, and riparian function may have been poor. It seems unlikely that catastrophes that would limit long life cycles were influential here because seven semivoltine taxa were found. Of the long-lived taxa, the elmid beetle *Optioservus* species (3.2 percent) and the caddisfly *Brachycentrus occidentalis* (1.7 percent) were common. Collector-filterers (31.2 percent), scrapers (29.2 percent), and shredders (27.7 percent) contributed similarly to the functional mix. Collector-gatherers (8.6 percent) were also well represented. These results suggested that both autochthonous materials (algal production within the reach) and allochthonous materials (fine and coarse particulate matter from sources outside the reach) were all important to the food web here.

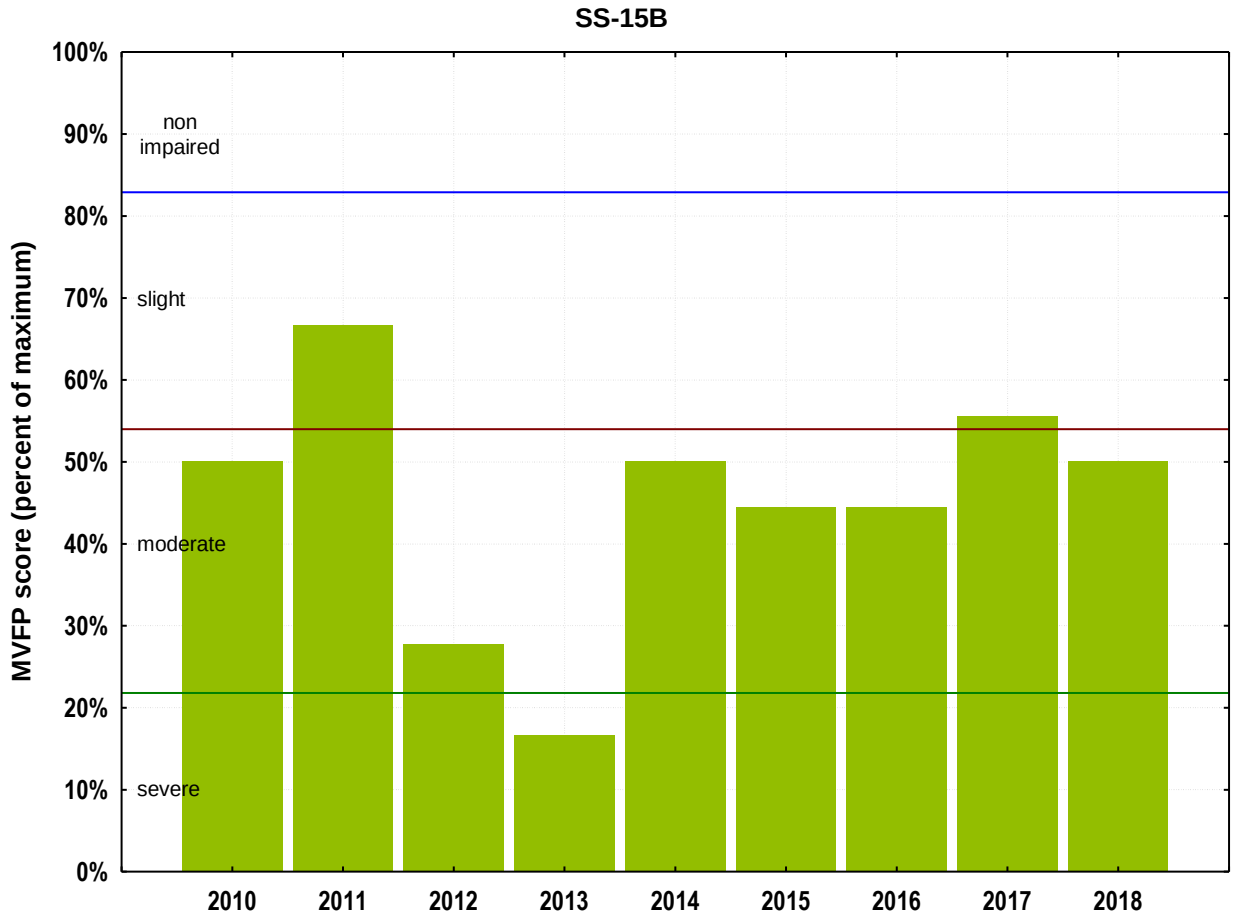

Figure 5-26. Montana Valley and Foothill Prairies (MVFP) bioassessment scores: comparison among years for Site SS-15B. Bars are labeled with impairment classifications.

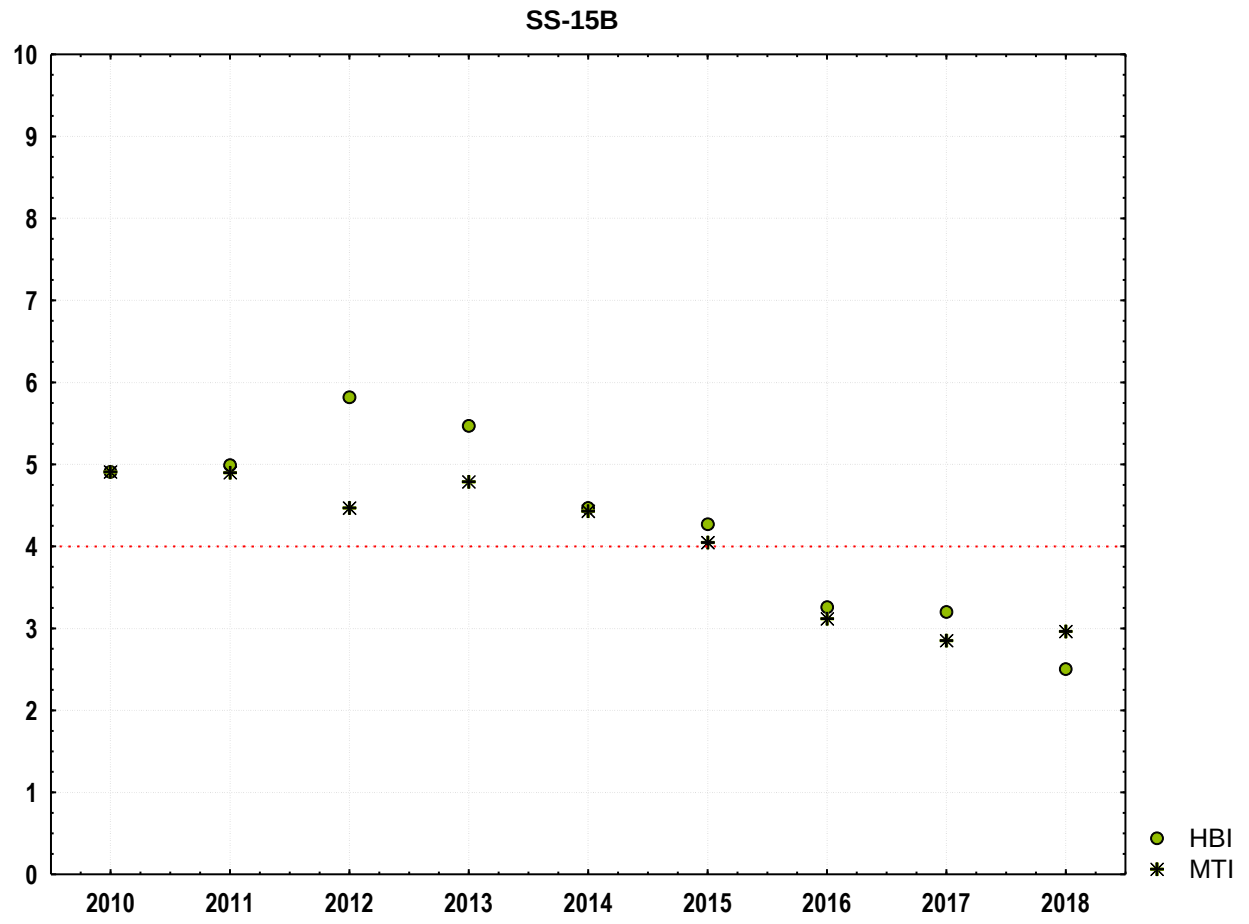

Figure 5-27. Hilsenhoff Biotic Index (HBI) and metals tolerance index (MTI) values: comparison among years for Site SS-15B. The red dashed line represents the "no impact" threshold for both metrics established by McGuire for the Clark Fork River basin.

5.3.3.13 SS-15G: German Gulch near Confluence

5.3.3.13.1 Comparisons among Years

MVFP scores at Site SS-15G indicated non-impaired conditions in 2018, which was similar to the ratings that were given to this site from 2010 to 2012 and higher than the slight impairment indicated from 2013 to 2017. Scores are graphed in Figure 5-28. Since 2010, the HBI has consistently indicated no evidence of nutrient enrichment and the MTI, according to McGuire's guidance, has also indicated no evidence of impairment by metals contamination (Figure 5-29).

5.3.3.13.2 2018 Data

5.3.3.13.2.1 Water quality

Most invertebrate characteristics suggested that water quality was good at this site in 2018. Site SS-15G had the greatest number of mayfly taxa (7) recorded from any site in 2018. Mayflies included the abundant heptageniids *Cinygmula* species (10.8 percent) and *Rhithrogena* species (2.2 percent) and *Baetis tricaudatus* complex (8.9 percent) as well as the pollution-sensitive ephemerellids *Drunella doddsii* (0.7 percent), *D. grandis* (0.2 percent) and *Caudatella* sp (0.9 percent). The HBI (3.50) indicated little impact from organic pollution. No hemoglobin-bearing organisms were obtained in this sample. There were also seven pollution-sensitive taxa collected. In addition to the pollution-sensitive mayflies described above, the midge *Cricotopus* (*Nostococladius*) species (0.6 percent), the stoneflies *Doroneuria* species (0.9 percent) and Leuctridae (0.2 percent) and the caddisfly *Dolophilodes* species (1.3 percent) were found. Pollution-tolerant organisms (2.6 percent) made up only a small percentage of the assemblage. The only attribute of the assemblage that indicated poor water quality was the higher than expected percentage of collector-filterers (46.6 percent). This high value was primarily due to the large percentage of blackflies (*Simulium* species, 44.7 percent, the dominant organism in the sample) collected. This gregarious taxon often occurs in large numbers in kicknet collections. The MTI (3.81) was below the threshold indicating metals contamination. This fact, combined with the high abundances of organisms with demonstrated sensitivity to metals, including heptageniid mayflies (*Cinygmula* species was the second most abundant organism in the sample) suggested that metals did not influence this reach.

5.3.3.13.2.2 Thermal condition

Six cold-stenotherm taxa making up 4.7 percent of the assemblage were found in this sample: no cold-loving taxa were reported from any other site in 2018. Consequently, like 2016 and 2017, it is not surprising that the temperature preference of this assemblage (13.3 C) was the lowest of any site studied in 2018.

5.3.3.13.2.3 Sediment deposition

Six caddisfly taxa (3 were abundant or common) and 21 "clinger" taxa were found in this sample. The FSBI-2000 (4.23) indicated an assemblage with moderate sediment tolerance and

the FSBI-2012 was 160. The high FSBI-2012 suggested that the stream bottom sediments were made up of less than 20 percent fine material. Sediment deposition probably did not appreciably limit colonization of stony substrates in this reach.

5.3.3.13.2.4 Habitat diversity and integrity

Overall taxa richness (40) was only somewhat lower than expected and seven stonefly taxa were collected, including the common *Zapada cinctipes* (2.4 percent) and *Hesperoperla pacifica* (3.9 percent). Thus, it seems unlikely that instream and reach-scale habitat features such as streambanks, channel morphology, and riparian zone function were somewhat disturbed. Catastrophes that would abort long life cycles were probably not influential here as seven semivoltine taxa were found in this sample and some of them were abundant (e.g., *H. pacifica;* the caddisfly *Arctopsyche* species, 2.4 percent). Collector-filterers (46.6 percent) were the most abundant functional group. All other functional components were represented in apparently appropriate proportions. These results suggested that both autochthonous (instream algal production) and allochthonous (fine and coarse particulate organic matter from upstream and riparian zones) energy sources were important in this reach.

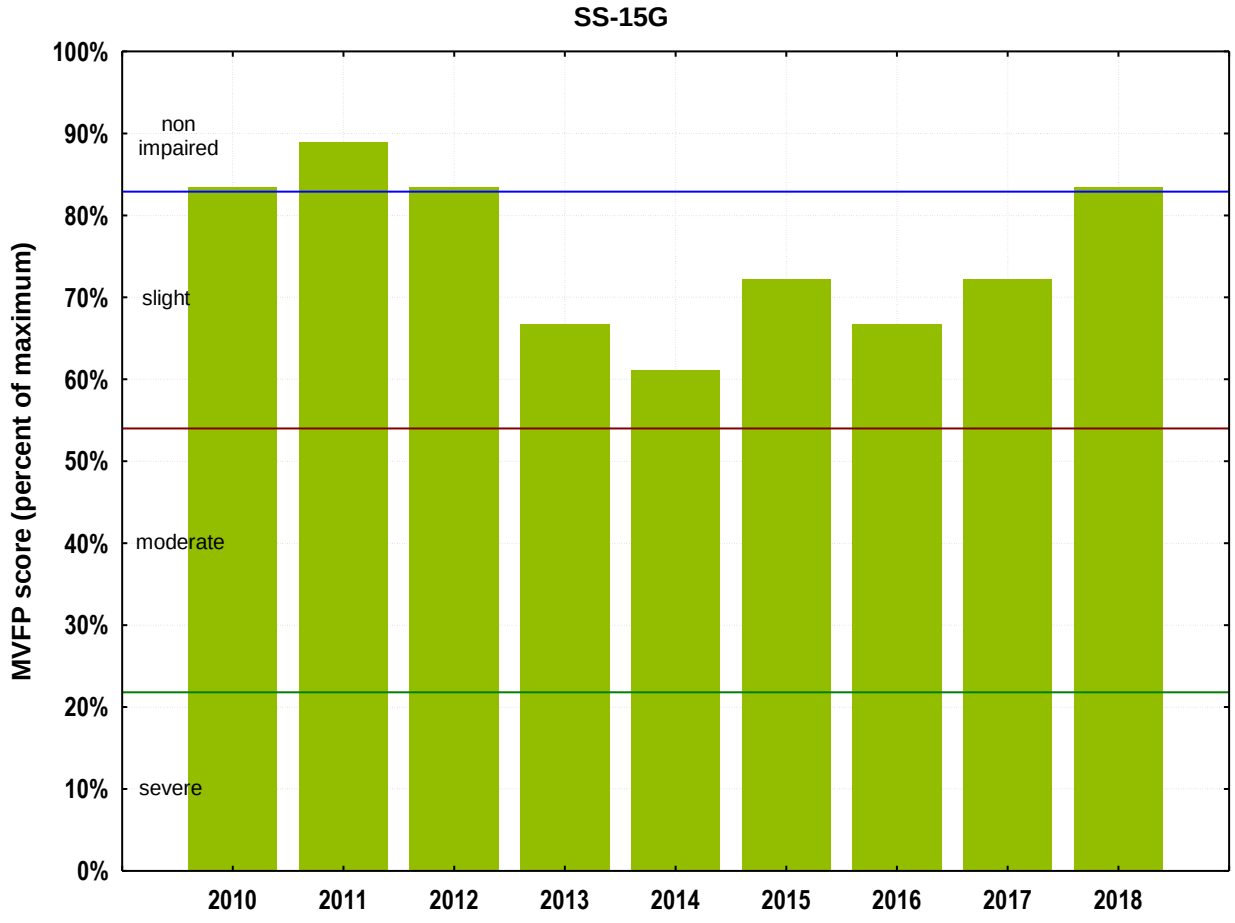

Figure 5-28. Montana Valley and Foothill Prairies (MVFP) bioassessment scores: comparison among years for Site SS-15G. Bars are labeled with impairment classifications.

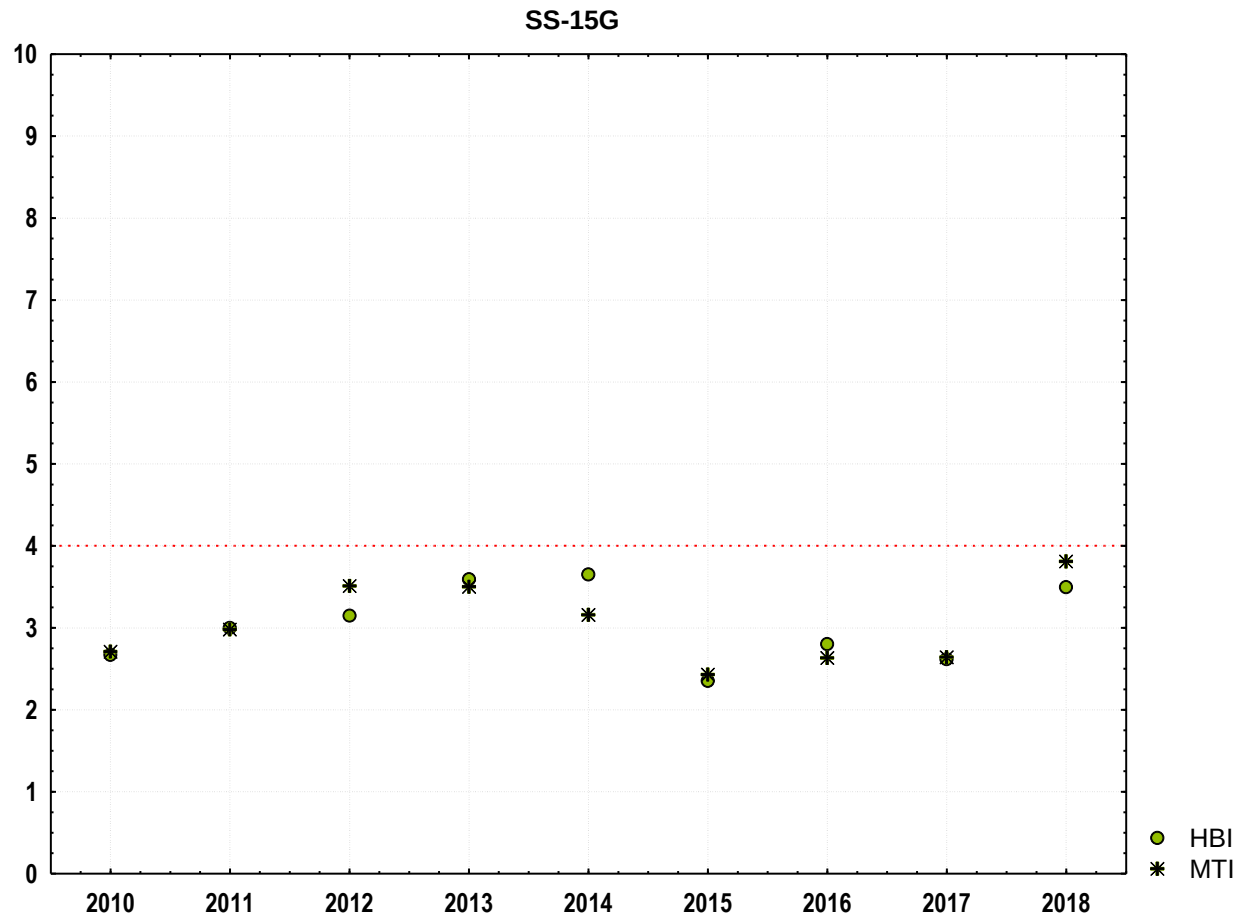

Figure 5-29. Hilsenhoff Biotic Index (HBI) and metals tolerance index (MTI) values: comparison among years for Site SS-15G. The red dashed line represents the "no impact" threshold for both metrics established by McGuire for the Clark Fork River basin.

5.3.3.14 SS-16B: Silver Bow Creek in Reach P near Fairmont

5.3.3.14.1 Comparisons among Years

Like 2106 and 2017, the MVFP index indicated moderate impairment in 2018 at Site SS-16B. This site was rated as severely impaired from 2013 (the first year samples were taken here) to 2015 (Figure 5-30). In 2018, the HBI fell below the threshold indicating impairment by nutrient enrichment. The HBI scored below this threshold in all years but 2017. Similarly, the MTI (according to McGuire's guidance) indicated no impairment by metals contamination in 2018 and 2013 to 2016 with slight impairment only indicated in 2017 (Figure 5-31).

5.3.3.14.2 2018 Data

5.3.3.14.2.1 Water quality

Water quality degradation cannot be ruled out in this reach based on the ecological attributes of the invertebrate assemblage collected in 2018. Several characteristics suggested that water quality was impaired. Mayflies were represented by only two taxa, *Baetis tricaudatus* complex (0.6 percent) and *Drunella* sp, (1.0 percent). Collector-filterers (21.6 percent) were abundant. No pollution-sensitive taxa were collected and the abundance of pollution-tolerant organisms (19.9 percent) exceeded expectations. In addition, hemoglobin-bearing organisms made up 0.08 percent of the assemblage so hypoxic sediments cannot be ruled out. However, the HBI (2.07) was low. The MTI (2.26) was also low, and the caddisfly *Lepidostoma* species (49.1 percent) was the most abundant animal in the sample: these findings suggest that metals contamination did not influence this reach.

5.3.3.14.2.2 Thermal condition

No cold-stenotherm taxa were found in the sample and organisms that prefer warm water, including the caddisflies *Helicopsyche* species (10.3 percent) and *Oecetis* species (1.3 percent), were collected. The temperature preference calculated for the assemblage at this site was 15.9 C.

5.3.3.14.2.3 Sediment deposition

An FSBI-2000 of 3.27 suggested that the assemblage was sediment-tolerant and an FSBI-2012 of 20 did not contradict this hypothesis. However, nine caddisfly taxa, several of which were abundant, and 14 "clinger" taxa were counted from the sample. Given this information, it appeared that slight impediment of invertebrate colonization of this reach by fine sediment cannot be ruled out here in 2018.

5.3.3.14.2.4 Habitat diversity and integrity

Overall taxa richness (23) was low: instream habitats may have been monotonous or disrupted. Only one specimen of one stonefly taxon (*Skwala* species) was found here: this may be related to altered channel morphology, loss of riparian function, or unstable streambanks. There were three long-lived taxa in the sample: *Brachycentrus occidentalis* (12.0 percent), *Optioservus* species (4.4 percent) and *Zaitzevia* species (0.2 percent). Consequently, catastrophes such as dewatering, scour, toxic pollutants, or thermal extremes appeared to be unlikely at this site. Shredders (49.1

percent) were the dominant functional group as a result of the abundance of the caddisfly *Lepidostoma* species Other functional groups occurred in expected proportions.

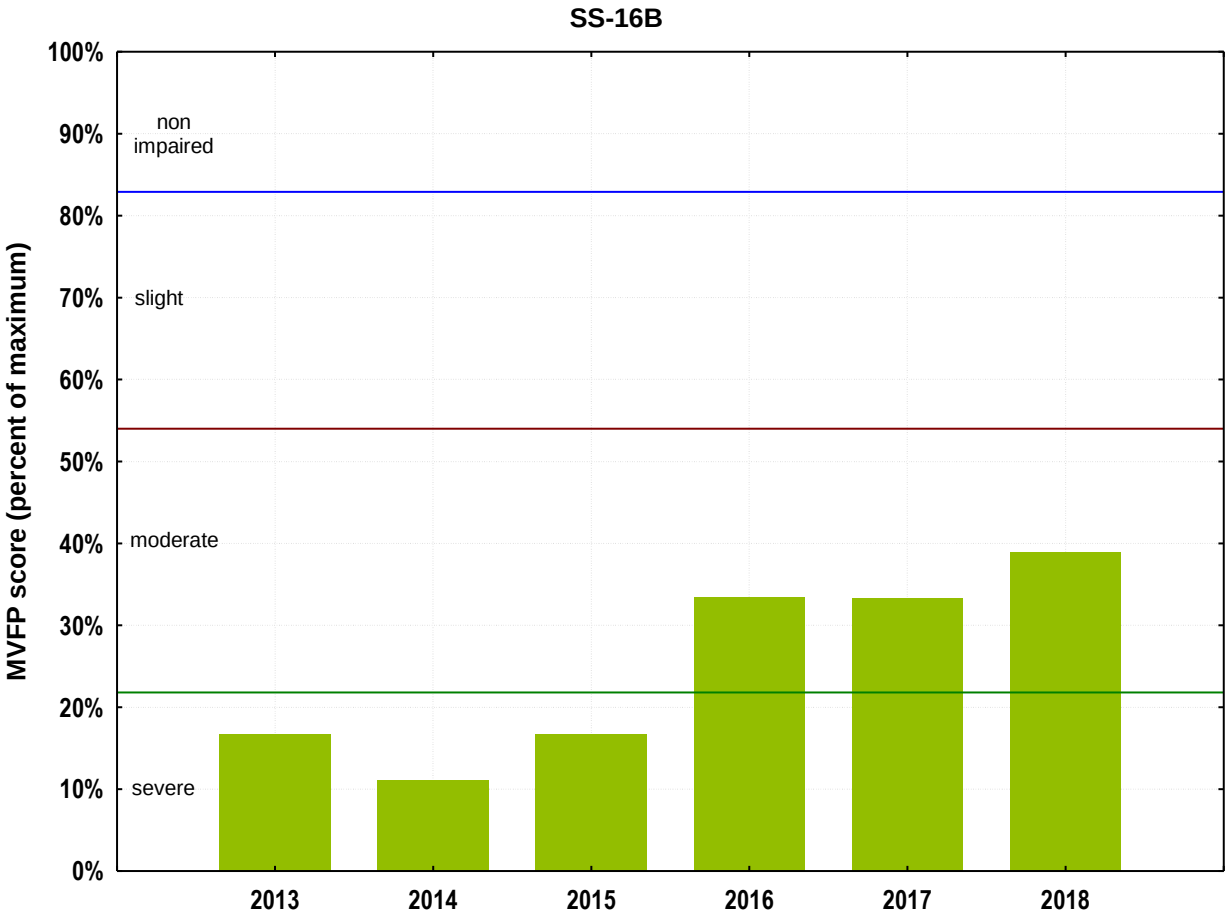

Figure 5-30. Montana Valley and Foothill Prairies (MVFP) bioassessment scores: comparison among years for Site SS-16B. Bars are labeled with impairment classifications.

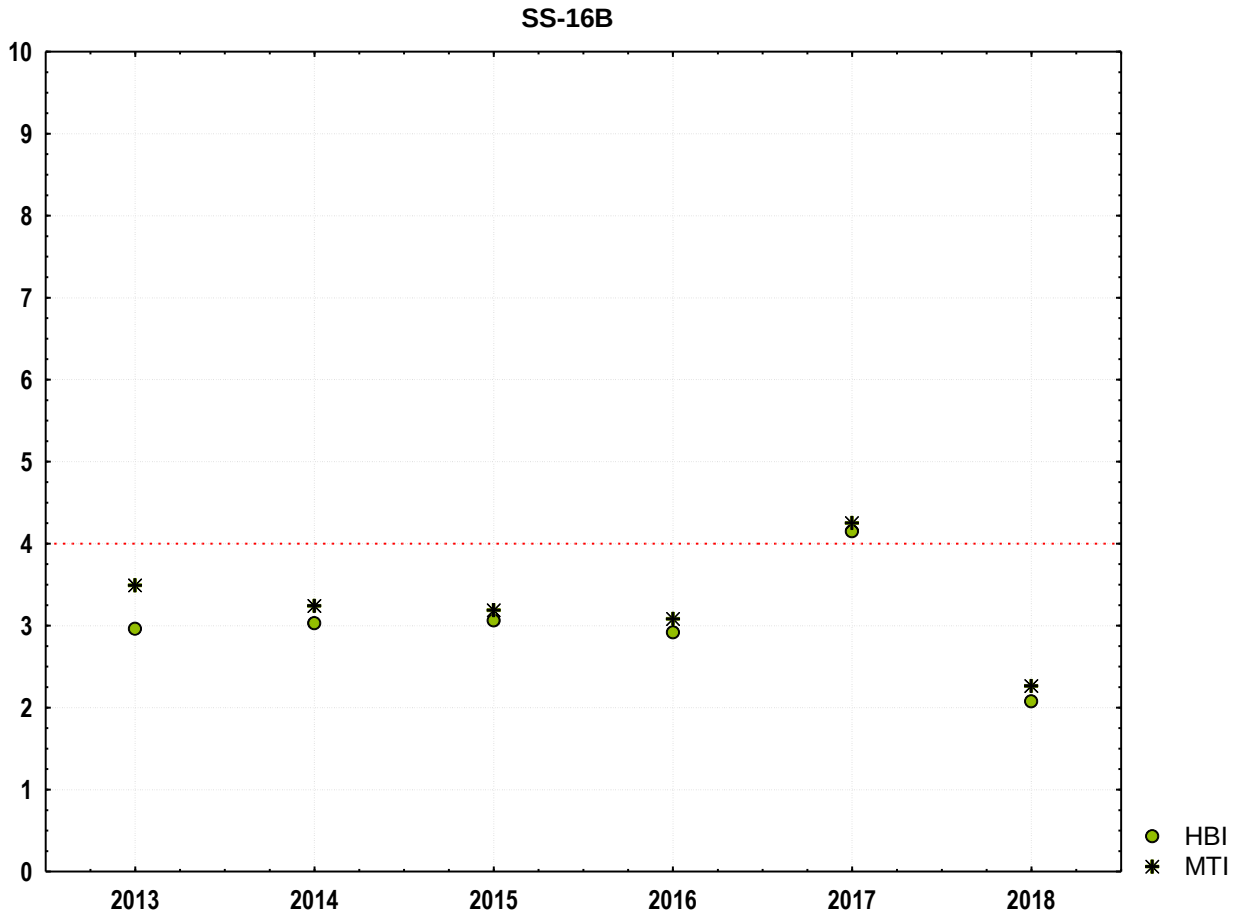

Figure 5-31. Hilsenhoff Biotic Index (HBI) and metals tolerance index (MTI) values: comparison among years for Site SS-16B. The red dashed line represents the "no impact" threshold for both metrics established by McGuire for the Clark Fork River basin.

5.3.3.15 SS-17D: Silver Bow Creek below Stewart Street at Opportunity

5.3.3.15.1 Comparisons among Years

The MVFP indicated moderate impairment at Site SS-17D in 2018 and in eight out of the nine years the site has been sampled: only in 2012 was the site rated as severely impaired (Figure 5-32). In 2018, the HBI and MTI metrics indicated no impairment by nutrient enrichment or metals contamination at this site according to McGuire's guidance (Figure 5-33). In most other years, these metrics varied between unimpaired to slightly impaired.

5.3.3.15.2 2018 Data

5.3.3.15.2.1 Water quality

Similar to Site SS-16B, water quality degradation cannot be dismissed at Site SS-17D as attributes of the invertebrate assemblage gave mixed results. Only one mayfly taxon was recorded (*Baetis tricaudatus* complex) and it was represented by only two specimens (0.4 percent). No pollution-sensitive taxa were collected and pollution-tolerant organisms (8.2 percent) slightly exceeded expectations. Collector-filterers (17.7 percent) also exceeded expectations. Sediments may have been hypoxic at times because hemoglobin-bearing organisms (1.5 percent) were common. On the other hand, the HBI (1.52) indicated little impact from organic pollution. However, given the balance of invertebrate metrics, impairment through nutrient enrichment cannot be dismissed at this site. The MTI (2.18) did not indicate impairment by metals, a conclusion that is also supported by the abundance of organisms that are sensitive to metals (i.e., *Lepidostoma* species, 39.2 percent, the most abundant taxon in the sample).

5.3.3.15.2.2 Thermal condition

The temperature preference of the assemblage was calculated at 15.7 C. No cold-stenotherm taxa were collected and organisms that prefer warm water, including the caddisflies *Helicopsyche* species (1.7 percent) and *Oecetis* species (0.4 percent), were reported from this sample.

5.3.3.15.2.3 Sediment deposition

The FSBI-2000 value (3.96) indicated a moderately sediment-tolerant assemblage. The FSBI-2012 was 10. Seven caddisfly taxa, including *Lepidostoma* species and *Glossosoma* species (32.1 percent), the two most abundant taxa in the sample, and 11 "clinger" taxa were counted. Colonization of stony substrates by invertebrates may have been slightly impeded.

5.3.3.15.2.4 Habitat diversity and integrity

Overall taxa richness (26) was below expectations for a low-to-mid order stream in the Middle Rockies ecoregion, suggesting that instream habitats may have been monotonous or disturbed in this reach. Only two stonefly taxa, the perlodids *Skwala* species (1.3 percent) and *Isoperla* species (0.2 percent), were reported from the sample, suggesting that reach-scale habitat features such as streambanks, channel morphology, or riparian function may have been disturbed. Three semivoltine taxa were collected: of these, *Optioservus* species (3.0 percent) and *Brachycentrus occidentalis* (8.0 percent) were abundant. Consequently, catastrophes that would interrupt long

life cycles seem unlikely here. Shedders (39.4 percent, primarily *Lepidostoma* sp) and scrapers (37.5 percent, primarily *Glossosoma* species) strongly dominated the functional composition of the assemblage, suggesting that both allochthonous and autochthonous production were important to the food web. Other functional groups were within expectations.

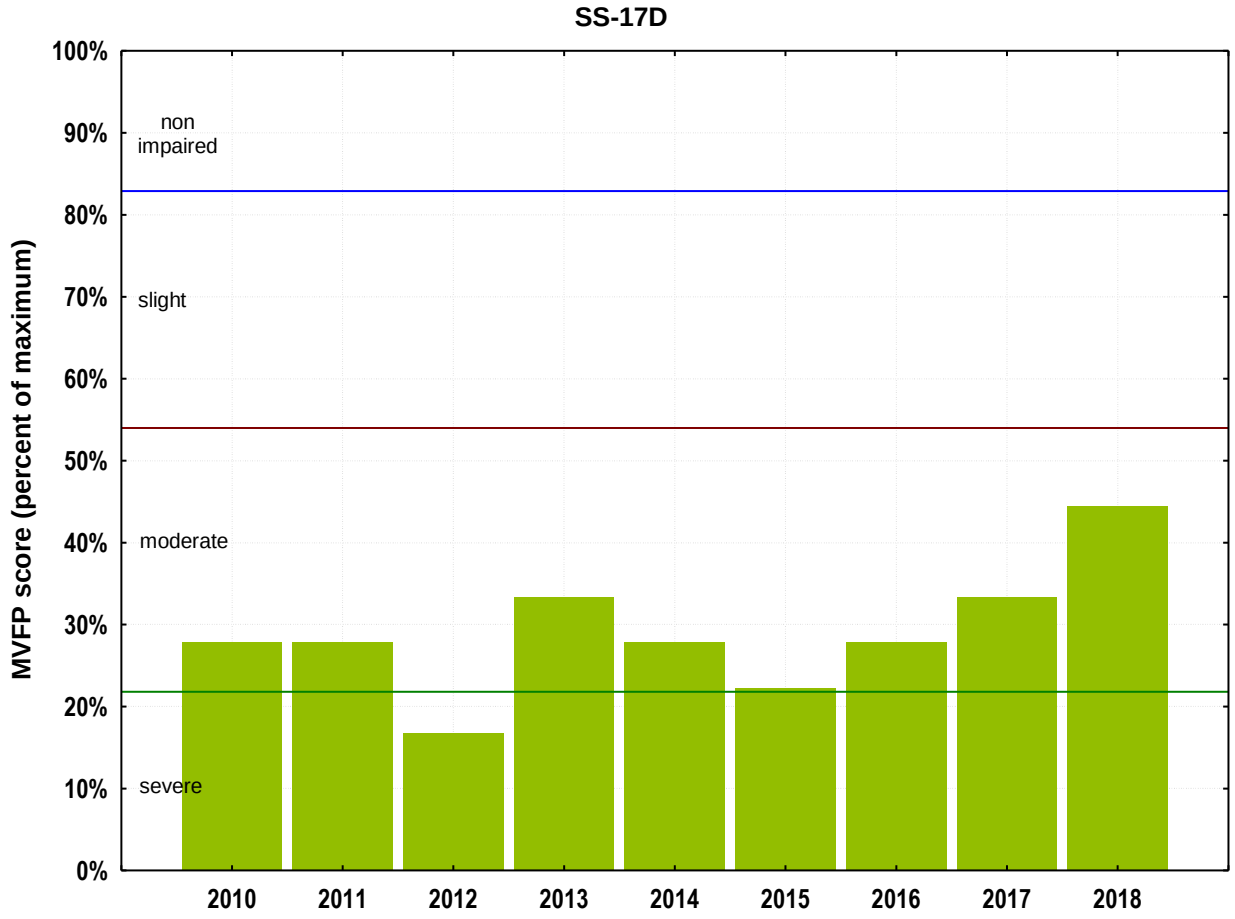

Figure 5-32. Montana Valley and Foothill Prairies (MVFP) bioassessment scores: comparison among years for Site SS-17D. Bars are labeled with impairment classifications.

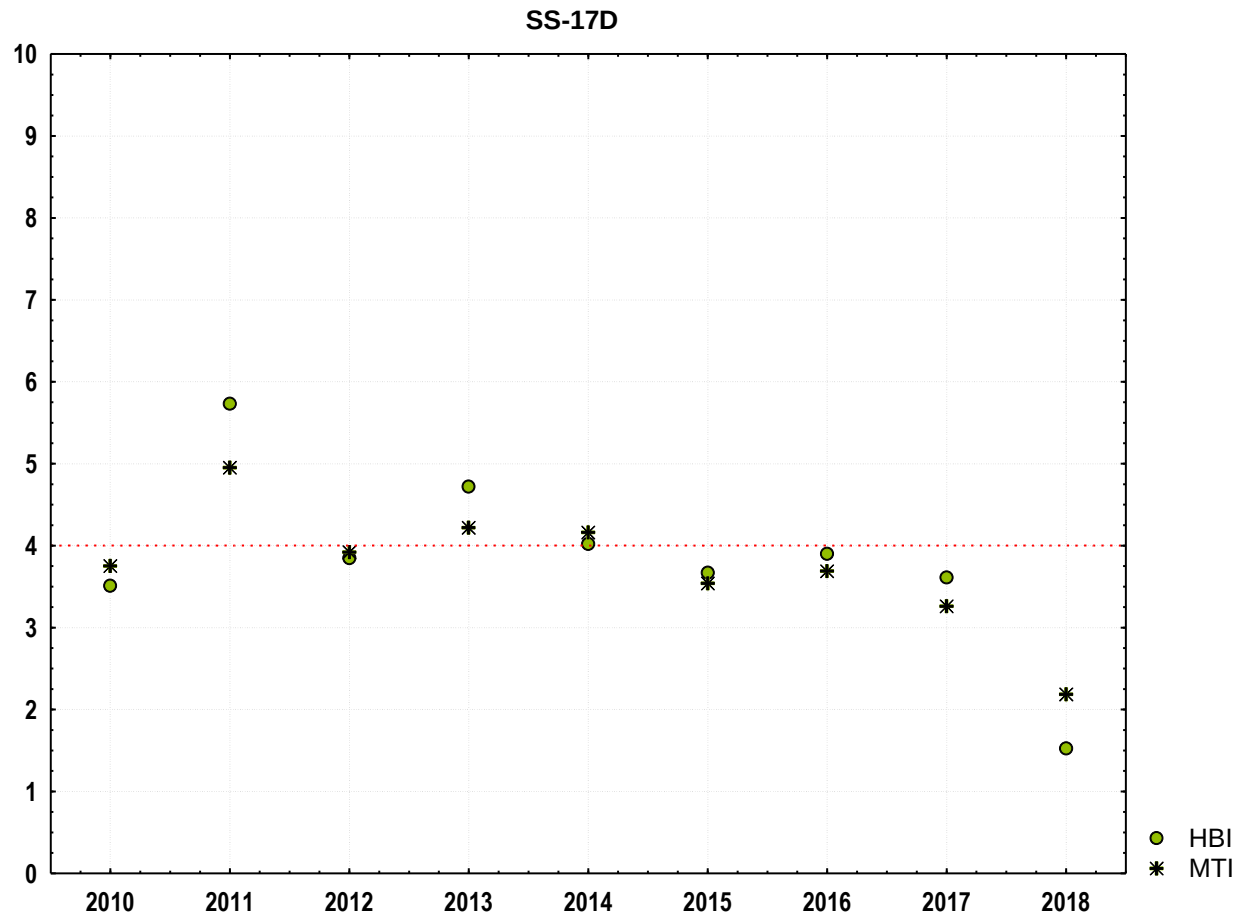

Figure 5-33. Hilsenhoff Biotic Index (HBI) and metals tolerance index (MTI) values: comparison among years for Site SS-17D. The red dashed line represents the "no impact" threshold for both metrics established by McGuire for the Clark Fork River basin.

5.3.3.16 SS-19: Silver Bow Creek at Frontage Road

5.3.3.16.1 Comparisons among Years

Moderate impairment continued to be indicated by the MVFP index at Site SS-19 in 2018 (Figure 5-34). Neither the MTI metric (according to McGuire's guidance) nor the HBI index provided evidence for impairment by metals or nutrients in 2018 (Figure 5-35). In previous years these metrics vacillated between slight impact to no impact.

5.3.3.16.2 2018 Data

5.3.3.16.2.1 Water quality

The mayfly fauna recorded from this reach was not diverse (3 taxa) and the taxa were not abundant (*Baetis tricaudatus* complex, 0.8 percent; *Attenella* species, 0.2 percent; *Tricorythodes* species, 1.0 percent). The HBI (2.77) suggested that the assemblage was not impacted by organic pollution. However, pollution-tolerant organisms made up 17.0 percent of the sample and no pollution-sensitive taxa were collected. The percentage of filter-feeders (31.8 percent) was above expectations, and hemoglobin-bearing taxa (7.1 percent), including the midge *Microtendipes* species (6.5 percent), were very common in this assemblage. These findings suggest that water quality impairment through nutrient enrichment cannot be ruled out here, and that there was additional stress associated with hypoxic conditions in the sediment. Contamination by metals was not indicated because the MTI (2.71) was low and the caddisfly *Lepidostoma* species (41.0 percent) was abundant in the sample.

5.3.3.16.2.2 Thermal condition

Similar to most sites, no cold-stenotherm taxa were recorded here. The temperature preference of the assemblage was 16.8 C. Warm-water loving taxa (e.g., *Helicopsyche* species, 8.0 percent) were abundant.

5.3.3.16.2.3 Sediment deposition

Seven caddisfly taxa (6 were abundant) and 11 "clinger" taxa were found in this sample. The FSBI-2000 value (3.46) indicated a sediment-tolerant assemblage. The FSBI-2012 was 20. Given the low value for the FSBI-2000, the negative effects of fine sediment deposition on colonization of stony sediments by invertebrates cannot be ruled out here.

5.3.3.16.2.4 Habitat diversity and integrity

Overall taxa richness (24) was lower than expected and only two stonefly taxa were collected; neither of them (*Isoperla* species, 0.4 percent; *Skwala* species, 0.4 percent) were common. Consequently, monotonous or disturbed instream habitats and unstable streambanks, loss of riparian function, or altered channel morphology were suggested. Catastrophic dewatering, thermal extremes, sediment pulses or toxic inputs were probably unlikely because three long-lived taxa were collected, including the caddisfly *Brachycentrus occidentalis* (11.8 percent) and the elmid beetle *Optioservus* species (6.1 percent). Shredders (41.0 percent) and collector-filterers (31.8 percent) dominated the functional composition of the assemblage and all other functional

groups were well represented. Thus, both fine and coarse particulate matter and instream algal production appeared to be the important energy sources in this reach.

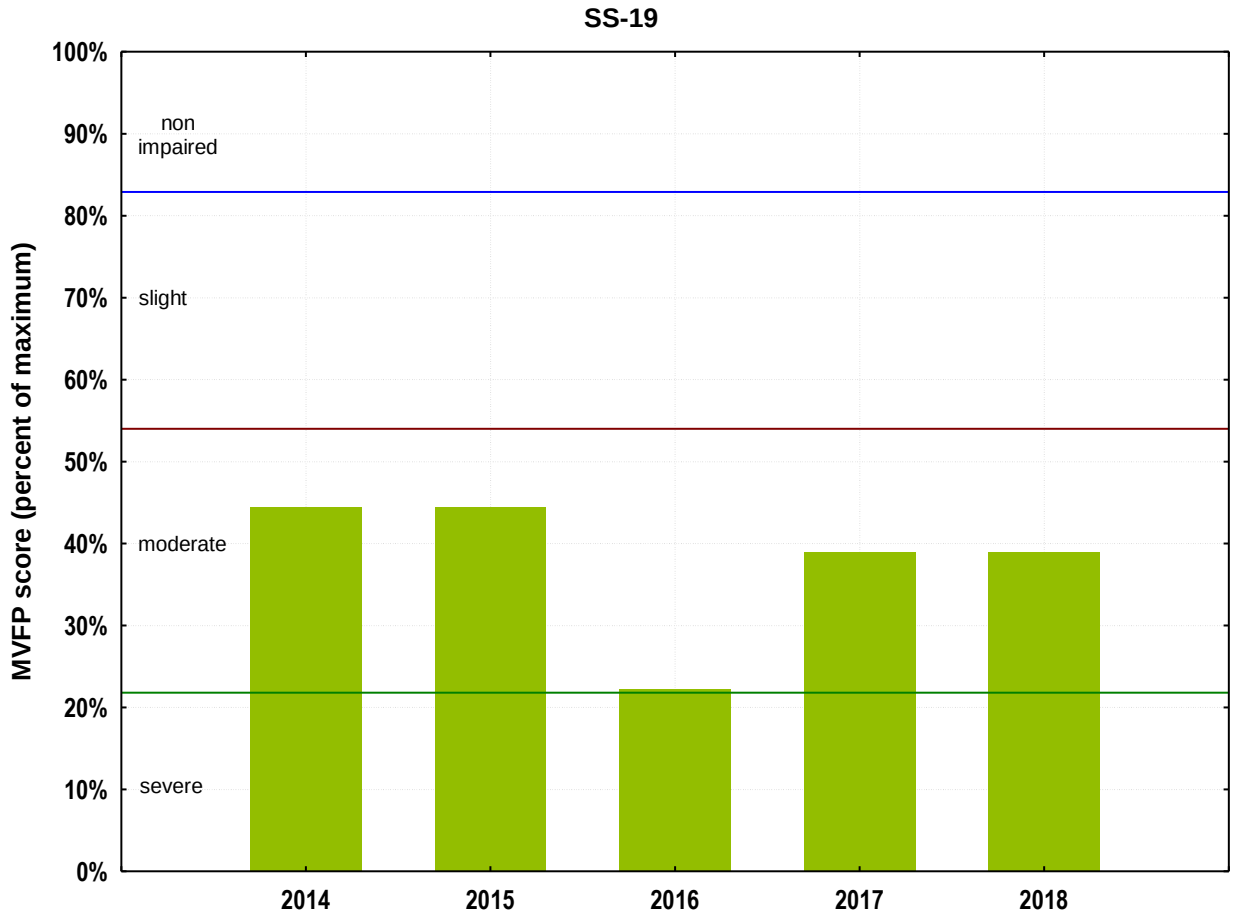

Figure 5-34. Montana Valley and Foothill Prairies (MVFP) bioassessment scores: comparison among years for Site SS-19. Bars are labeled with impairment classifications.

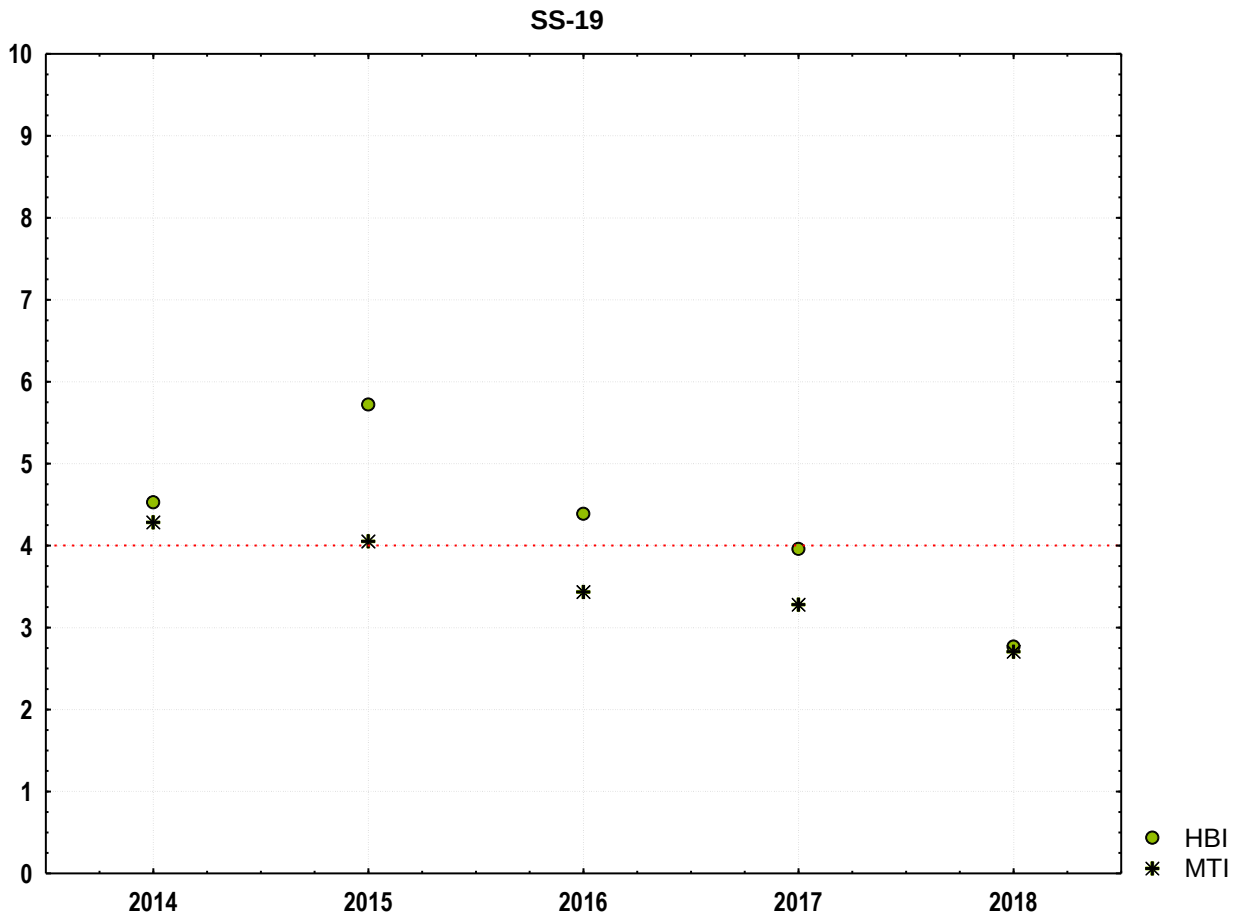

Figure 5-35. Hilsenhoff Biotic Index (HBI) and metals tolerance index (MTI) values: comparison among years for Site SS-19. The red dashed line represents the "no impact" threshold for both metrics established by McGuire for the Clark Fork River basin.

5.4 DISCUSSION

Based on the evidence from the aquatic invertebrate assemblages, the MVFP index indicated that biological integrity was impaired at all sites except Site SS-15G, whereas the O/E index indicated that all sites were impaired in 2018. Of the sites classified as impaired by the MVFP index, moderate impairment was indicated at all sites except Site SS-08 which was categorized as severely impaired (Table 5-6; Figure 5-1). Table 5-7 summarizes the probable stressors judged to be influential, based on the taxonomic composition and attributes (function, tolerance, physiology, habitus, etc.) of organisms identified at each site.

Aquatic invertebrate assemblages generally suggested that at least a portion of the impaired biological integrity indicated at all sites except at German Gulch near confluence (Site SS-15G) was the result of nutrient enrichment. From the upstream-most site (Blacktail Creek at Father Sheehan Park (Site SS-01)) through Miles Crossing (Site SS-14D), water quality appeared impaired by nutrient enrichment. There was some indication of nutrient enrichment at Silver Bow above (Site SS-15A-2) and below (Site SS-15B) German Gulch and sites SS-16B (Silver Bow in Reach P near Fairmont through Site SS-19 (Silver Bow Creek at Frontage Road); however, not all invertebrate indicators suggested nutrient enrichment at these locations.

Hypoxic sediments were indicated at the most upstream site (Blacktail Creek at Father Sheehan Park; Site SS-01) and could not be ruled out at Silver Bow Creek above the Butte Reduction Works (Site SS-05A) and at Silver Bow Creek at Rocker (Site SS-08). Beginning with Site SS-10A (Silver Bow Creek above Sand Creek), hypoxic sediments were suggested at all sites through Site SS-14D (Silver Bow Creek at Miles Crossing). Hypoxic conditions could not be ruled out in Reach P near Fairmont (Site SS-16B) and was indicated at the site below Stewart St Opportunity (Site SS-17D) and at the Frontage Road (Site SS-19).

Evidence for the influence of sediment deposition was equivocal at all sites: however, the combination of invertebrate attributes at most sites suggested that slight inhibition of colonization of invertebrates by fine sediment could not be ruled out. General trends were that caddisfly taxa richness was within expectations or slightly lower than expectations at most sites, whereas “clinger” taxa richness tended to be quite a bit lower at most sites. The Fine Sediment Biotic Index (FSBI-2000) indicated sediment-tolerant or moderately sediment-tolerant assemblages at all sites except Blacktail Creek at Father Sheehan Park (Site SS-01). Only at sites SS-15B (Silver Bow below German Gulch) and SS-15G (German Gulch near confluence) was “clinger” taxa richness high and the FSBI-2012 did not indicate significant fine sediment deposition.

Based on the performance of the Metals Tolerance Index (MTI) and the taxonomic composition of the aquatic invertebrate fauna, evidence for the influence of metals contamination was detected at Site SS-01 through Site SS-10A. In addition, the MTI was slightly elevated at Site SS-11C.

Investigation of the invertebrate assemblages suggested that the habitat was disrupted at most sites. No habitat disruption was indicated at German Gulch (Site SS-15G). In addition, only

at Silver Bow Creek below Browns Gulch (Site SS-11D) and Silver Bow Creek at the Frontage Road (Site SS-19) was the faunal evidence equivocal about whether habitat disruption was influential.

Table 5-7. Predicted stressors at each site, based on the taxonomic composition and attributes of biological assemblages.[54]

6.0 PERIPHYTON[55]

6.1 INTRODUCTION

Silver Bow Creek is a tributary to the Clark Fork River that extends from Butte, Montana approximately 23 miles downstream to the Warm Springs Ponds just north of Opportunity, Montana. Silver Bow Creek was impacted by mining waste and municipal sewage inputs from the 1870s through the 1980s. The earliest impacts resulted from underground mining and included waste rock, slag, and mill tailings that were deposited directly into the stream. In 1908 a major flood redistributed the waste rock and tailings downstream throughout the channel and floodplain. Mining efforts in the area shifted to open-pit operations with the 1955 opening of the Berkeley Pit mine near Butte. Open-pit mining ceased in the Berkeley Pit in 1982; however, copper precipitate is currently mined from the waters of the Berkeley Pit and mining continues in the nearby Continental Pit (molybdenum and copper). The ancestral headwaters of Silver Bow Creek have now been entirely subsumed into the Berkeley and Continental Pits and the city of Butte metro sewer system.

Silver Bow Creek and its adjacent floodplain have undergone major remediation that included excavation and removal of tailings and impacted soils from the floodplain, replacement of the removed tailings with local fill material, seeding and planting of vegetation, and reconstruction of the stream channel. Major remediation was completed in all subareas during 2017, but minor remedial actions occurred in Subareas 1 and 2 to remove some remnant tailings. The portion of the creek and its adjacent floodplain undergoing remediation is designated the Streamside Tailings Operable Unit (SSTOU) and is divided into four subareas. Remediation has already been accomplished in some subareas. A plan was established to monitor several factors as remediation progressed including surface water, instream sediments, geomorphology, groundwater, and aquatic biologic resources including periphyton (benthic algae).

This report describes results of periphyton monitoring in 2018 within the SSTOU of the Silver Bow Creek/Butte Area National Priorities List site. A total of 16 sites were sampled, including 14 sites on Silver Bow Creek, one site on German Gulch, and one site on Blacktail Creek. One site, Silver Bow Creek below Sand Creek (Site SS-10B) was eliminated from the monitoring network in 2017. In addition, the long-term monitoring site in Silver Bow Creek above German Gulch (Site SS-15A) was discontinued and replaced by an alternate site (Site SS-15A-2), which was located approximately 150 m upstream in 2018. This change occurred because Site SS-15A was thought to not represent most of the stream channel condition in Subarea 3 above German Gulch. Site SS-15A is in a short (approximately 0.3 stream km), narrow, bedrock chute with residual tailings. This portion of the floodplain was not remediated because removal of the tailings in this narrow chute was determined to be not worth the effort given the tight working space and poor access for

[55] Chapter 6 was prepared by W. Bollman and B. Kerans of Rhithron Associates Inc. (Missoula, Montana) with minor editing and formatting by RESPEC.

heavy equipment coupled with the low volume of tailings. All the other streambed and floodplain portions of Subarea 3 above German Gulch (approximately 6.5 stream km) were remediated.

Several approaches were used to examine the periphyton samples. The taxonomy and assemblage structure of non-diatom (soft-bodied) algae and diatom (silica-walled) algae were examined. A suite of analytical metrics was applied to the diatom data to assess the degree of impairment from metals, nutrients, and sedimentation. These metrics included a stressor-specific tool developed for the Middle Rockies Ecoregion [Teply 2010a; 2010b] and adopted by Montana Department of Environmental Quality (DEQ) as a periphyton standard operating procedure for determining the probability of sediment impairment [DEQ, 2011]. In addition, a variety of diatom metrics developed for Montana mountain streams were used [Bahls et al., 1992; Bahls, 1993; Teply and Bahls, 2005]. These metrics were based on autecological preferences or requirements of freshwater diatoms [Lowe, 1974; Van Dam et al., 1994; Bahls, 2006]. Site-specific narratives were also used to describe probable stressors to water quality and habitat integrity. These narratives were based on taxonomic and functional composition of the benthic flora.

6.2 METHODS

6.2.1 Sampling

Periphyton samples were collected at 16 sites on Silver Bow Creek (14 sites), Blacktail Creek (1 site) and German Gulch (1 site) from September 17-21, 2018 (Table 6-1). One composite periphyton sample was collected from multiple substrates and habitat types at each site. Periphyton samples were collected following the DEQ PERI-1 method for flowing streams where a defined reach has not been established [DEQ, 2011]. Periphyton samples were preserved in the field with Lugols solution and transported to the laboratory on ice.

Table 6-1. Periphyton sampling locations in the Streamside Tailings Operable Unit, September 17-21, 2018.

Site ID	Site Location	Location (GPS coordinates; NAD 83)

SS-19	Silver Bow Creek at Frontage Road	45.98523	-112.50772

6.2.2 Laboratory Analysis

After the periphyton samples were preserved with Lugols solution and taken to the laboratory, initial sample volumes were measured and recorded. The samples were thoroughly mixed by shaking and split into two aliquots for analyses of soft-bodied algae and diatoms

6.2.2.1 Non-Diatom Algae

For soft-bodied algal samples, the raw periphyton sample was manually homogenized and emptied into a porcelain evaporating dish. A small, random sub-sample of algal material was pipetted into a standard Palmer-Maloney counting chamber using a disposable Pasteur pipette. Visible (macroscopic) algae were also sub-sampled, in proportion to their estimated abundance relative to the total volume of algal material in the sample and added to the liquid fraction on the slide. The Palmer-Maloney cell was then covered with a 22x30 mm coverslip.

Soft-bodied (non-diatom) algae were identified to genus using a Leica DM 2500 compound microscope under 200X and 400X magnification. The relative abundance of each algal genus (and of all diatom genera collectively) was estimated for comparative purposes, according to the following system:

- rare (R): fewer than 1 cell per field of view at 200X, on the average;

- common (C): at least 1 but fewer than 5 cells per field of view;
- very common (VC): between 5 and 25 cells per field of view;
- abundant (A): more than 25 cells per field of view, but countable;
- very abundant (VA): number of cells per field of view too numerous to count.

Algae (all non-diatom genera and the diatoms as one unit) were also ranked according to their estimated contribution to the total algal biovolume present in the sample. The genus (or Division in the case of the diatoms) with the most biomass ranked number 1; the genus with the next most biomass ranked number 2, and so on. Rare (R) taxa were recorded with a biomass rank of 0.

6.2.2.2 Diatom Algae

Permanent diatom slides were prepared: subsamples were taken and treated with 70 percent nitric acid (HNO_3) and digested using a closed-vessel microwave digestion system (Milestone Ethos EZ), following the method developed by the Academy of Natural Sciences, Philadelphia [ANSP, 2002]. The samples were neutralized by rinses with distilled water, and subsample volumes were adjusted to obtain adequate densities for slide mounts. Dilution and concentration factors, as appropriate, were recorded for each sample. Subsamples were dried onto 22-mm square coverslips. Coverslips were mounted on slides using Naphrax diatom mount. To ensure a high-quality mount for identification and to make replicates available for archives, two slide mounts were made from each sample. One of the replicates was selected from each sample batch for identification. A diamond scribe mark was made to define a transect line on the cover slip, and a minimum of 800 diatom valves were identified along the transect mark. A Leica DM 2500 compound microscope, Nomarski contrast, and 1000x magnification were used for identifications. Diatoms were identified to the lowest possible taxonomic level, generally species.

6.2.3 Data Analysis

Results of periphyton taxonomic analyses are summarized using three general approaches: (1) taxa richness and diversity, (2) diatom bioassessment indices, and (3) site-specific narratives that include ecological interpretations of the taxa richness and diversity and bioassessment analyses as well as other pertinent information about the assemblages.

6.2.3.1 Taxa Richness and Diversity

Taxa richness for non-diatom taxa and diatom taxa richness and diversity were examined separately to provide a general understanding of the periphyton assemblages within each sample. Non-diatom taxa richness was summarized by genus within taxonomic division for each site. More detailed summaries of estimated relative abundance and generic diversity within each non-diatom sample are provided in Appendix H. Diatom taxa richness and Shannon diversity were compared in each sample to evaluate general trends among sites. In the case of diatoms, species-level, including variants, were used. Detailed summaries of the diatom assemblages at each site can be found in Appendix I.

6.2.3.2 Diatom Bioassessment Indices

Taxonomic results for diatom sample analysis were used to calculate an array of bioassessment indices within each sample. Three general types of bioassessment tools were applied to each: Increaser Taxa bioindices [DEQ, 2011; Teply, 2010a], Diatom Association Metrics for Montana Mountain Streams [Bahls, 1993], and Ecological Indicator Values of Freshwater Diatoms [Van Dam et al., 1994]. Each bioassessment index generates a value summarizing the degree of impairment to the diatom assemblage at each site. Some indices are designed to represent impairment from specific environmental stressors (e.g., amount of dissolved oxygen) whereas others represent general impairment.

6.2.3.2.1 Increaser Taxa

Each periphyton sample was evaluated according to DEQ's current periphyton standard operating procedure [DEQ, 2011] using "pollutant-diagnosing biometrics based on stressor-specific increaser diatom taxa as described in Teply [2010a; 2010b]". The pollutant-diagnosing biometrics described in DEQ [2011] are known as "increaser taxa" and are specifically designed to diagnose stress from sediments and nutrients. According to DEQ [2011], "the assessment tools have been designed to function properly in the presence (or absence) of the other stressor types". For the Middle Rockies ecoregion, the DEQ has adopted only the sediment biometric. Teply [2010a] also provides guidance for a metal-increaser taxon biometric to diagnose stress from metal contamination although that metal-specific biometric was not adopted by DEQ [2011]. However, because each increaser taxa biometric provides estimates of the probability of impairment for each specific stressor of interest, the impairment probabilities for all 3 biometrics are summarized in this report.

6.2.3.2.2 Diatom Association Metrics for Montana Mountain Streams

In addition to the diatom bioassessment indices, we used seven diatom association metrics to augment assessments of impairment (Table 6-2). Each of these seven diatom association metrics provides a general measure of environmental impairment to the diatom assemblage. Results from each site were tabulated and sites were rated on impairment based on the criteria listed in Table 6-2. We also combined these additional metrics into an index that evaluates overall biointegrity at each site. The following paragraphs summarize each metric.

Species richness is a common measure of environmental impairment with greater richness generally reflecting more heterogeneous environmental conditions. Low taxa richness generally reflects environmental homogeneity, which may be the result of several specific stressors such as metal contamination or nutrient enrichment. Bahls [1979] used species richness as a measure of diatom biointegrity.

The diversity index is based on the Shannon diversity index which includes measures of species evenness and taxa richness and is sensitive to variation in water quality [Bahls, 1993].

Pollution tolerance groups, defined by Lange-Bertalot [1979], diatom autecological profiles described by Lowe [1974] and unpublished Montana diatom data described in Bahls [2006] were combined in the Pollution Index [Bahls, 1993]. This index rates diatom tolerance to nutrient enrichment, minerals, elevated temperatures, or metal toxicity. Diatom species are assigned a score from 1-3: a score of 1 corresponds to "most-tolerant", a score of 2 corresponds to "less-tolerant", and a score of 3 corresponds to "sensitive."

The Siltation Index examines the percentage of diatom taxa associated with fine sediments [Bahls, 1993; Teply and Bahls, 2005]), Many diatom species are motile. Motility is thought to be an adaptation to siltation whereby individual diatom cells can move to avoid inundation by deposited sediment. The Siltation Index [Bahls, 1993] is calculated as the total percent abundance of motile diatom taxa which include species belonging to the genera Navicula, Nitzschia, Surirella and other closely related taxa.

The disturbance index [Barbour et al., 1999] is based on the percent relative abundance of the diatom *Achnanthidium minutissimum*, which is highly specialized in the post-disturbance recolonization of stream substrates. Elevated numbers may be indicative of recent environmental stress caused by elevated or highly variable stream flows, water velocities, and water temperatures at a site. Care must be taken in the interpretation of this metric because this diatom may also be the dominant species in swiftly flowing mountain streams because of the naturally occurring disturbances there.

The relative abundance of the dominant diatom [Teply and Bahls, 2005] in an assemblage is a measure of the evenness; the greater the percentage of organisms in the dominant taxon, the more skewed is the assemblage. The underlying principle is that a healthy and stable assemblage will be more even with a relatively consistent division of its organisms into taxa.

The percentage of abnormal diatom valves examines the relative abundance of diatom valves with irregular outlines and abnormal ornamentation. McFarland et al. [1997] examined the percentage of abnormal diatom (*Fragilaria* species) valves in a Rocky Mountain river in Colorado. Abnormal valves ranged from 0.2-12.0 percent and the percentage was positively correlated to the amounts of metals (cadmium, copper, iron, and zinc) found in the river. These data suggested that morphologically abnormal diatoms may be an indicator of elevated dissolved metal concentrations in streams.

An overall biointegrity rating was assigned for each monitoring site based on the individual bioassessment metrics (Table 6-2; RESPEC [2018b]). This overall rating was determined using a series of steps. First, at each site, scores were assigned for each diatom association metric on an ordinal scale: "excellent" = 3, "good" = 2, "fair" = 1, and "poor" = 0. Second, the mean score of those seven metrics at each site was calculated. The mean score of the seven metrics was then used as the overall biointegrity rating on another ordinal scale: "excellent" = more than 2.7, "good" = 1.7-2.7, "fair" = 0.7-1.7, and "poor" = less than 0.7.

Table 6-2. Summary of diatom association metrics to evaluate biological integrity in mountain streams: references range of values, expected response to increasing impairment or stress.

Metric	Biological Integrity				Range	Expected Response	Reference
	Excellent	Good	Fair	Poor			
Species Richness	>29	20-29	19-10	<10	0-100+	decrease	Bahls, 1993
Diversity Index	>2.99	2.00-2.99	1.00-1.99	<1.00	0-5+	decrease	Bahls, 1993
Pollution Index	>2.50	2.01-2.50	1.50-2.00	<1.5	1-3	decrease	Bahls, 1993
Siltation Index	<20.0	20.0-39.9	40.0-59.9	>59.9	0-90+	increase	Bahls, 1993
Disturbance Index	<25.0	25.0-49.9	50.0-74.9	>74.9	0-100	increase	Barbour et al., 1999
Dominant Species (%)	<25.0	25.0-49.9	50.0-74.9	>74.9	~5-100	increase	Barbour et al., 1999
Abnormal Valves (%)	0	>0.0, <3.0	3.0-9.9	>9.9	0-30+	increase	McFarland et al., 1997

6.2.3.2.3 Freshwater Diatoms as Ecological Indicators

Van Dam et al. [1994] identified diatom taxa considered to be indicators of specific conditions. Conditions identified by the Van Dam et al. [1994] indicator taxa included organic nitrogen tolerance and hypoxia tolerance.

Most diatoms are nitrogen-autotrophs and are unable to directly utilize organic nitrogen. For some nitrogen-autotrophs, organic nitrogen may be toxic. Some diatoms directly assimilate organic nitrogen in addition to, or as an alternative to, inorganic nitrogen (i.e., facultative nitrogen heterotrophs). Van Dam et al. [1994] classified diatom species by trophic state, either as nitrogen-autotrophs or nitrogen heterotrophs. Relative abundances of diatoms in each group were quantified for each site. Nitrogen-heterotroph relative abundance is expected to generally increase in relation to organic nitrogen concentrations and the opposite relationship is expected for nitrogen-autotrophs intolerant of organic nitrogen.

Some diatoms are intolerant of saprobic conditions (i.e., waters with excessive organic materials in various states of decomposition resulting in high biochemical oxygen demand and 75 percent dissolved oxygen saturation) [Van Dam et al., 1994]. Diatoms with such sensitivities are referred to as oligosaprobous or ß-mesosaprobous and would likely be found in low relative abundance in water with excessive organic pollution. Similarly, water with low dissolved oxygen saturation would likely have few species sensitive to hypoxia. The relative abundance oligosaprobous or ß-mesosaprobous diatoms and oxygen-sensitive diatoms were summarized by site.

6.2.3.3 Ecological Interpretations

Narrative interpretations were used to investigate and describe metric and taxonomic signals for water quality, sediment deposition and habitat indicators. These interpretations of the taxonomic and functional composition of the diatom assemblage were based on demonstrated associations between assemblage components and habitat and water quality variables gleaned from the published literature and professional judgment, and those of other expert sources (e.g., Teply and Bahls [2005]; [2006]; [2007a]). Often canonical procedures have been used for stressor identification; however, the substantial data required for such procedures (e.g., surveys of habitat, historical and current data related to water quality, land use, point and non-point source influences, soils, hydrology, geology) were not readily available for this study. Instead, attributes of the periphyton taxa that have been well-substantiated in diverse literature, including both published and unpublished research, and that have been generally accepted by regional aquatic ecologists, were combined into descriptions of probable water quality and instream and reach-scale habitat conditions. The approach to this analysis used some assemblage attributes that were interpreted as evidence of water quality and other attributes that were interpreted as evidence of habitat integrity.

Periphyton assemblages have been used as indicators of water quality [Stevenson, 2014]. Algal assemblages are especially sensitive to nutrient enrichment (e.g., Black et al. [2011]; Waite [2014]; Piggott et al. [2015]) and nutrient tolerance values have been established for many taxa (e.g., Van Dam et al. [1994]; Fairchild et al. [1985]; Carrick et al. [1988]; Teply and Bahls [2006]; Bahls [2004]; [2005]; [2006]). Worldwide diatom taxa with specific tolerances to saprobity (e.g., Van Dam et al. [1994]), organic pollution (e.g., Lange-Bertalot [1979]), salinity (e.g., Van Dam et al. [1994]), conductivity and ionic composition (Potapova and Charles [2003]), and fine sediment and adaptations to sediment (e.g., Lowe [1974]; Lowe [2003]; Stoermer and Smol [1999]) and general habitat disturbance (e.g., Lange-Bertalot [1996]) have been identified.

In the site-specific narratives, we compiled the information from the indices and metrics described above with ecological and autecological characteristics which were established specifically for taxa of the northwestern United States and Montana (Bahls, 2004; 2005; 2006). The narratives also examined 2 metrics that have been studied in Montana streams. These include the relative abundance of metals-tolerant taxa [Teply and Bahls,2005and the percentage of motile and highly motile taxa (Teply and Bahls, 2005; taxa from J. Stevenson, *personal communication*; Hannaea, 2005). These metrics were examined to suggest the potential stressors (nutrients, metals, sediment) that may be influential at the specific sites.

In addition, we explored similarities and differences in diatom assemblage structure among sites. We did this by using a Principal Components Analysis (PCA) using the covariance matrix of diatom species-level data. We removed diatoms that were identified to genus only if species level data were available in the database. The genus *Hippodonta* was the only genus that was identified to only the generic level, thus that taxon remained in the ordination.

6.3 RESULTS

6.3.1 Taxa Richness and Diversity

6.3.1.1 Non-Diatoms

A total of 19 genera and 1 unique undetermined taxon of non-diatom algae, representing four divisions, were identified in the Silver Bow Creek watershed in 2018 (Figure 6-1). These included: 1 undetermined taxon of Rhodophyta (red algae), 9 genera of the Cyanophyta (blue-green algae), 9 genera of the Chlorophyta (green algae) and 1 genus of the Chrysophyta (the yellow-green alga *Vaucheria*).

Generic richness of non-diatom algae ranged from 1 to 8 among the Silver Bow watershed sites (Figure 6-1). Generally, richness appeared to be highest at the upstream most sites (Sites SS-01 through SS-08): the highest taxa richnesses of non-diatom algae were recorded at Sites SS-05A and SS-08. Taxa richnesses were low (between 3 to 5 taxa) at the middle sites (Sites SS-10A through SS-14). Downstream of Site SS-14 taxa richness varied considerably, from 7 taxa at Site SS-15A-2 to 1 taxon at Site SS-17D, which was the lowest non-diatom taxon richness recorded in 2018.

Green algae were present at all sites (Figure 6-1). Blue-green algae were present at all sites except Sites SS-07 and SS-17D. The chrysophytes were collected at 4 sites (Sites SS-07, SS-08, SS-11C and SS-15A-2). The red algae were also collected at 4 sites (Sites SS-05A, SS-06G, SS-08, and SS-15G). The general trend was for green algae to be the most taxonomically rich division at the upstream sites (Sites SS-01 though SS-08), whereas blue-green algal taxa richness tended to be highest in the intermediate sites (Sites SS-10A through SS-14). Below Site SS-14 the division with the greatest number of taxa varied considerably.

The relative abundance of each soft-bodied algal genus (and of all diatoms collectively) for each site is presented in Appendix H.

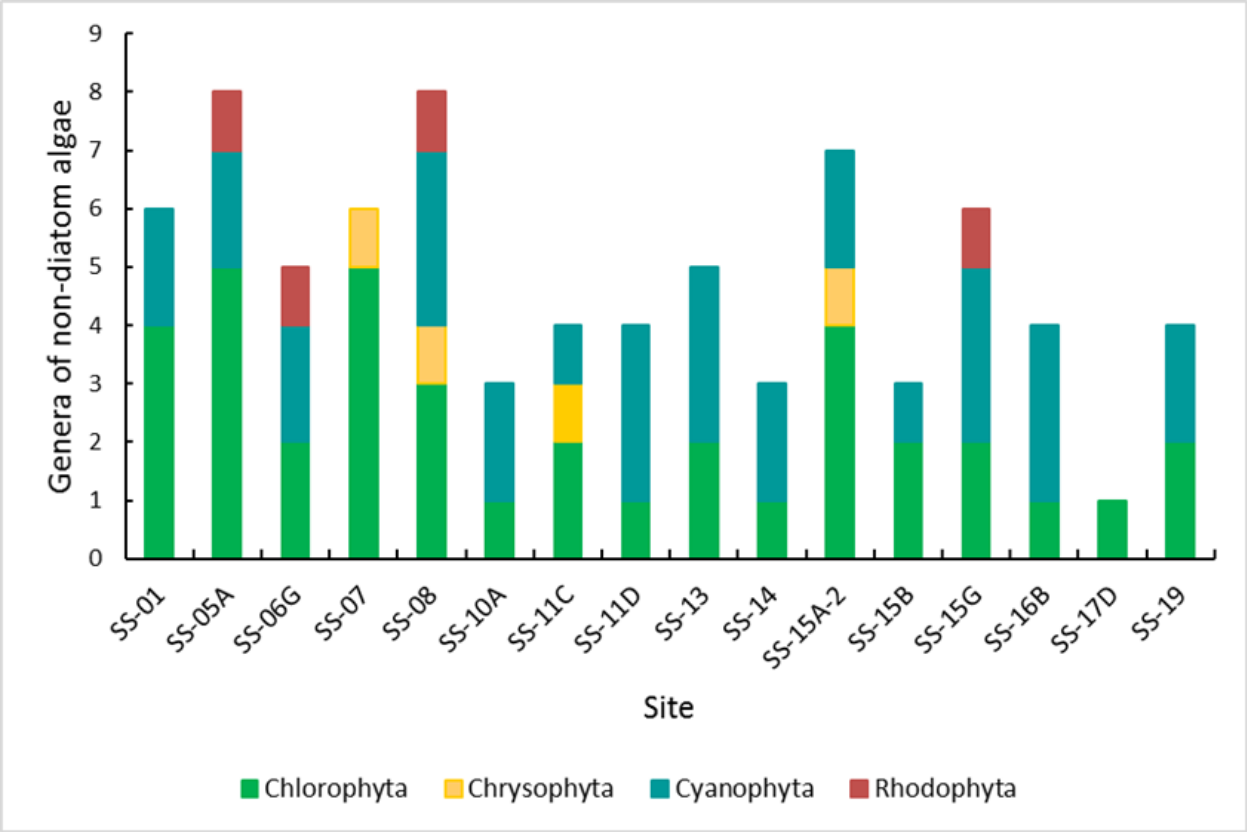

Figure 6-1. Taxonomic richness of non-diatom algae genera in the Silver Bow watershed, 2018.

6.3.1.2 Diatoms

A total of 136 diatom taxa, mostly species and including varieties and subspecies, in 49 genera were identified in the 2018 periphyton samples. Diatom genera that were commonly observed at a relative abundance of at least 3 percent across all samples included: *Nitzschia* (27.7 percent), *Staurosira* (4.0 percent), *Cocconeis* (5.7 percent), *Mayamaea* (18.9 percent), *Encyonema* (3.1 percent), *Planothidium* (7.7 percent), *Sellaphora* (14.0 percent), and *Navicula* (3.7 percent).

Diatom taxa richness varied between 34 and 63 (Figure 6-2). The general trend was for the upstream most sites (Sites SS-01, SS-05A, SS-06G, SS-07, SS-08) to have greater taxa richness (52 to 60) than the downstream sites (Sites SS-16B, SS-17D, SS-19) where richness varied between 34 and 37 taxa. Sites in between these two extremes (Sites SS-10A through site SS-15G) varied between a high of 55 taxa (Site SS-15B) and a low of 39 taxa (Site SS-13).

Shannon diversity varied between 3.26 and 5.02 (Figure 6-2). The upstream sites (Sites SS-01 through SS-08) had the highest diversities (all more than 4.51). Lowest diversities were found at Sites SS-13 (3.26), SS-16B (3.38), and SS-19 (3.27). The general trend in Shannon diversity was a fairly steady decline from Site SS-01 (5.02) through Site SS-13 (3.26). Diversity increased slightly from Site SS-13 (3.26) through Site SS-15G (4.09) and then declined at the three downstream-most sites: Site SS-16B (3.38), Site SS-17D (3.59), and Site SS-19 (3.27).

Trends in taxa richness and Shannon Diversity were generally similar, although they did diverge somewhat, probably because Shannon Diversity also considers taxa evenness as well as taxa richness.

Complete lists of species observed and counts for each species within each sample are provided in Appendix I.

Figure 6-2. Diatom species richness and Shannon Diversity values in the Silver Bow watershed, September 17-21, 2018.

6.3.2 Diatom Bioassessment Indices

6.3.2.1 Increaser Taxa

Impairment probabilities derived from increaser taxa bioindices are presented in Figure 6-3.

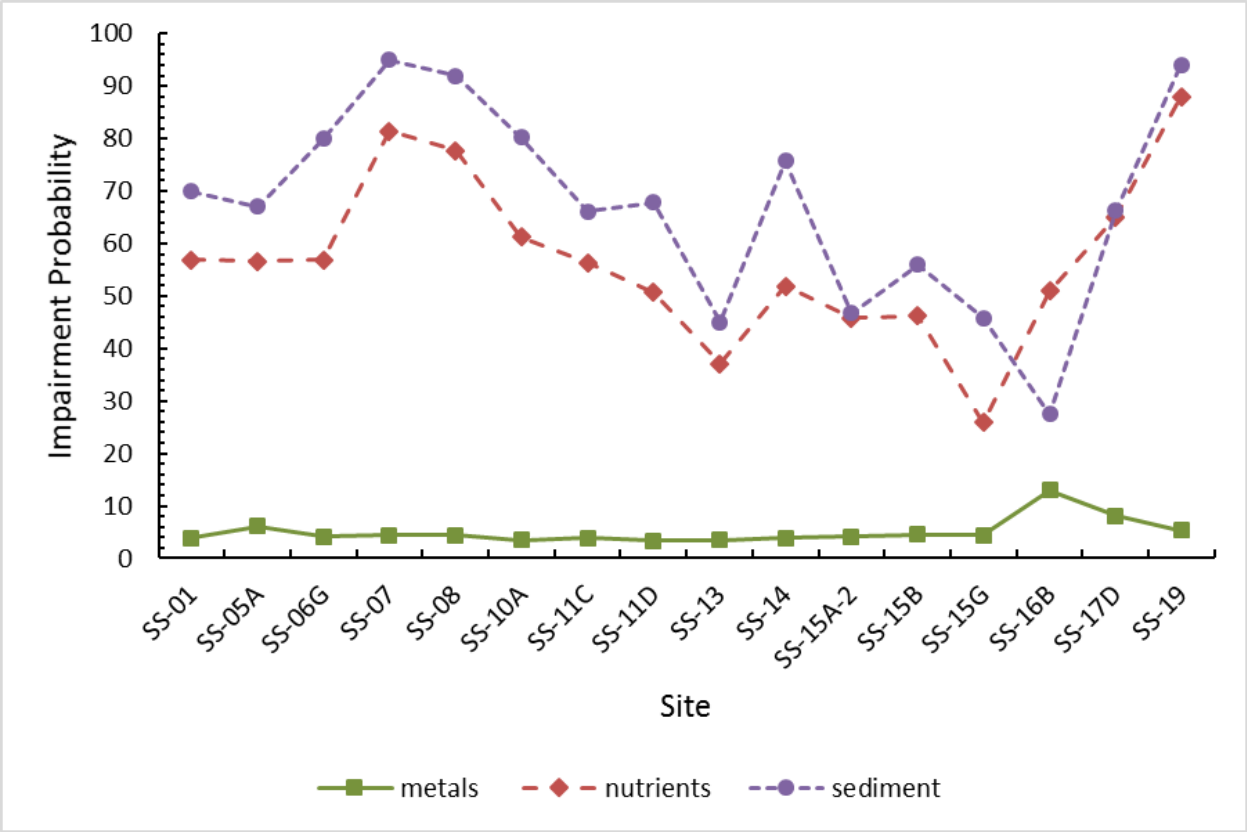

Figure 6-3. Impairment probabilities (expressed as a percentage) from specific environmental stressors at each site in the Silver Bow Creek watershed in 2018 based on relative abundances of specific diatom increaser taxa.

6.3.2.1.1 Sediment

The probability of impairment (all probabilities in this report are expressed as a percentage rather than proportions) from sediments in the Silver Bow Creek watershed ranged from 27.5 percent at Site SS-16B to a high of 95.0 percent at Site SS-07 based on the relative abundance of diatom species considered sediment increaser taxa (Figure 6-3). Unlike taxa richness and Shannon Diversity, sediment impairment probability generally tended to increase from Site SS-01 (70.0 percent) and Site SS-05A (67.1 percent) through Site SS-07 (95.0 percent, the highest value found in 2018 which was followed by a general decline through Site SS-13 (45.0 percent). The probability then jumped to 75.7 percent at Site SS-14 which was followed by another general decline to Site SS-16B (27.5 percent). Finally, there was a dramatic increase to Site SS-19 (94.1 percent), which was the second highest value found in 2018.

6.3.2.1.2 Metals

Based on the relative abundance of diatom metals increaser taxa, the probability of impairment from metals in the SSTOU ranged from 3.4 percent at Site SS-11D to 12.9 percent at Site SS-16B (Figure 6-3). The general trend was for all sites upstream of and including Site SS-

15G to have probabilities of impairment by metals between 3 percent and 5 percent, except for Site SS-05A where the probability was 6.2 percent. Probability of impairment by metals tended to be higher at the downstream sites (Sites SS-16B through SS-19) where the probabilities ranged between 5.4 percent and 12.9 percent.

6.3.2.1.3 Nutrients

Based on the relative abundance of diatom nutrient increaser taxa, the probability of impairment from nutrients ranged from 25.9 percent at Site SS-15G to 88.0 percent at Site SS-19 (Figure 6-3). The patterns for the probability of impairment by nutrients and the probability of impairment by sediments across sites were very similar.

6.3.2.2 Diatom Association Metrics for Montana Mountain Streams

Overall biological integrity, based on the mean value of the scores for all 7 metrics in Table 6-2 using the scoring criteria listed in the methods, was classified as "good" at all sites except Site SS-15G, which was classified as "excellent" (Table 6-3). Despite the "good" classification, every site had at least "minor".

impairment for at least two of Bahls [1993] metrics (Table 6-3). Ten sites were severely impaired based on the Siltation Index, but still were classified as having "good" biological integrity. In addition, 3 of the sites that were rated as severely impaired by the Siltation Index, were also rated as moderately impaired by the Pollution Index and they were still rated as "good".

Diatom species richness, Shannon Diversity, and the Disturbance Index indicated excellent water quality and no impairment at all sites (Table 6-3). Most sites were rated by the Pollution Index as having only minor impairment and good water quality. However, the Pollution Index rated Sites SS-10A, SS-11C, and SS-15A-2 as moderately impaired. Site SS-15G was the only site rated unimpaired by the Pollution Index. All sites were impaired based on the Siltation Index (Table 6-3). Sites SS-01 through SS-08 were rated as moderately impacted by fine sediment. The Siltation index rated all sites downstream of Site SS-08 as severely impacted except for Site SS-15G where the impact was rated as minor. The Dominant Taxon percentage metric indicated minor stress at 9 sites suggesting that diatom assemblage structure was impaired at these sites. Sites SS-07 and SS-16B were the only reaches where abnormal diatom valves were collected and rated a "good" for that reason.

As mentioned in the previous paragraph, all sites appeared to be impacted by multiple stressors based on the criteria in Table 6-2 because sediment and organic pollution impacted all sites to some degree. Sites SS-10A, SS-11C, and SS-15A-2 appeared to be the most stressed as they were moderately impacted by organic pollution and severely impacted by sediments. In addition, Sites SS-10A and SS-11C were also rated as having some minor impact to diatom assemblage structure by the Dominant Taxon metric.

Table 6-3. Diatom association metrics and biological integrity and impairment ratings for individual metrics and an overall score and rating for each site in the Silver Bow Creek watershed. September 17-21, 2018.[56]

Site	Site description	Diatom Species Richness	Shannon Diversity Index	Pollution Index	Siltation Index (%)	Disturbance Index (%)	Dominant Taxon (%)	Abnormal Cells (%)	Biological Integrity Score	Biological Integrity Rating
SS-01	Blacktail Creek at Father Sheehan Park	60	5	2.4	44.8	1.9	8.86	0	2.6	good
SS-05A	Silver Bow Creek above Butte Reduction Works	58	5	2.4	50.5	1.1	9.35	0	2.6	good
SS-06G	Silver Bow Creek above Butte WWTP	63	4.9	2.4	46.3	1.6	11.9	0	2.6	good
SS-07	Silver Bow Creek below Butte WWTP	52	4.5	2.4	51	1.7	18.2	0.1	2.4	good
SS-08	Silver Bow Creek at Rocker	57	4.6	2.4	54	1.4	20.7	0	2.6	good
SS-10A	Silver Bow Creek above Sand Creek	42	3.8	2	76.2	1.3	25.8	0	2.1	good
SS-11C	Silver Bow Creek above Browns Gulch	45	3.5	1.9	83.8	0.5	36.6	0	2.1	good
SS-11D	Silver Bow Creek below Browns Gulch	53	4	2	76	0.6	29.5	0	2.3	good
SS-13	Silver Bow Creek in Reach L	39	3.3	2.1	85.4	0	39.8	0	2.3	good
SS-14	Silver Bow Creek at Miles Crossing	48	3.8	2.2	76.5	1.4	30	0	2.3	good
SS-15A-2	Silver Bow Creek above German Gulch (Alternate Site)	47	3.9	2	77.1	0.4	24.4	0	2.3	good
SS-15G	German Gulch near confluence	43	4.1	2.7	32.1	6.9	29.5	0	2.7	excellent
SS-15B	Silver Bow Creek below German Gulch	55	4.3	2.1	70.3	1.1	24.4	0	2.4	good
SS-16B	Silver Bow Creek in Reach P near Fairmont	34	3.4	2.3	87	0.1	28.1	0.1	2.1	good
SS-17D	Silver Bow Creek below Stewart St at Opportunity	37	3.6	2.3	81.8	0.4	27.5	0	2.1	good
SS-19	Silver Bow Creek at Frontage Road	37	3.3	2.2	81.2	0.1	28.1	0	2.1	good

Minor impairment.

Moderate impairment.

Severe Impairment.

[56] Metric classifications were based on criteria in Table 6-2. Overall biological integrity scores were based on the techniques as described in the methods where scores were assigned for each diatom association metric on an ordinal scale: "excellent" = 3, "good" = 2, "fair" = 1, and "poor" = 0. The mean score of the 7 metrics at each site was used as to assign the overall biointegrity rating: "excellent" more than 2.7, "good" = 1.7-2.7, "fair" = 0.7-1.7, and "poor" less than 0.7.

6.3.2.3 Freshwater Diatoms as Ecological Indicators

6.3.2.3.1 Trophic State

The relative abundance of nitrogen-autotrophic diatoms intolerant of organic nitrogen ranged from 14.1 percent at Site SS-13 to 67.0 percent at Site SS-15G (Figure 6-4). Mean relative abundance of nitrogen-autotrophic diatoms was 32.0 percent (standard deviation [SD] = 14.8 percent). All sites had relative abundance of nitrogen-autotrophic diatoms within one SD of the mean except Site SS-01 (48.7 percent) and Site SS-15G (67.0 percent), which were above the threshold of 1 SD above the mean, and Site SS-11C (16.7 percent) and Site SS-13 (14.1 percent), which were below the threshold of 1 SD below the mean. The general trend was for the relative abundance of nitrogen-autotrophic diatoms intolerant of organic nitrogen to decline from Site SS-01 through Site SS-11C, fluctuate but remain relatively low from Site SS-11D through Site SS-15A-2, increase to its highest value at Site SS-16G, and then decline to low values at the downstream most sites.

The relative abundance of nitrogen-heterotrophic diatoms ranged from 3.0 percent at Site SS-15G to 28.9 percent at Site SS-16B) (Figure 6-4). Mean relative abundance of nitrogen-heterotrophic diatoms was 12.6 percent (SD = 6.6 percent). All sites had relative abundance of nitrogen-heterotrophic diatoms within one SD of the mean except Site SS-15A-2 (25.8 percent) and Site SS-16B (28.9 percent), which were above the threshold of 1 SD above the mean, and Site SS-16G (3.0 percent) and Site SS-19 (4.0 percent), which were below the threshold of 1 SD below the mean. Interestingly, the general pattern was for the relative abundance of nitrogen-heterotrophic diatoms to remain low from Site SS-01 through Site SS-14, peak at Site SS-15A-2 (25.8 percent), decline to the lowest value reported in 2018 at Site SS-15G (3.0 percent), increase again to a peak at Site SS-16B (28.9 percent) followed by another rapid decline to the second lowest value reported in 2018 at Site SS-19 (4.0 percent).

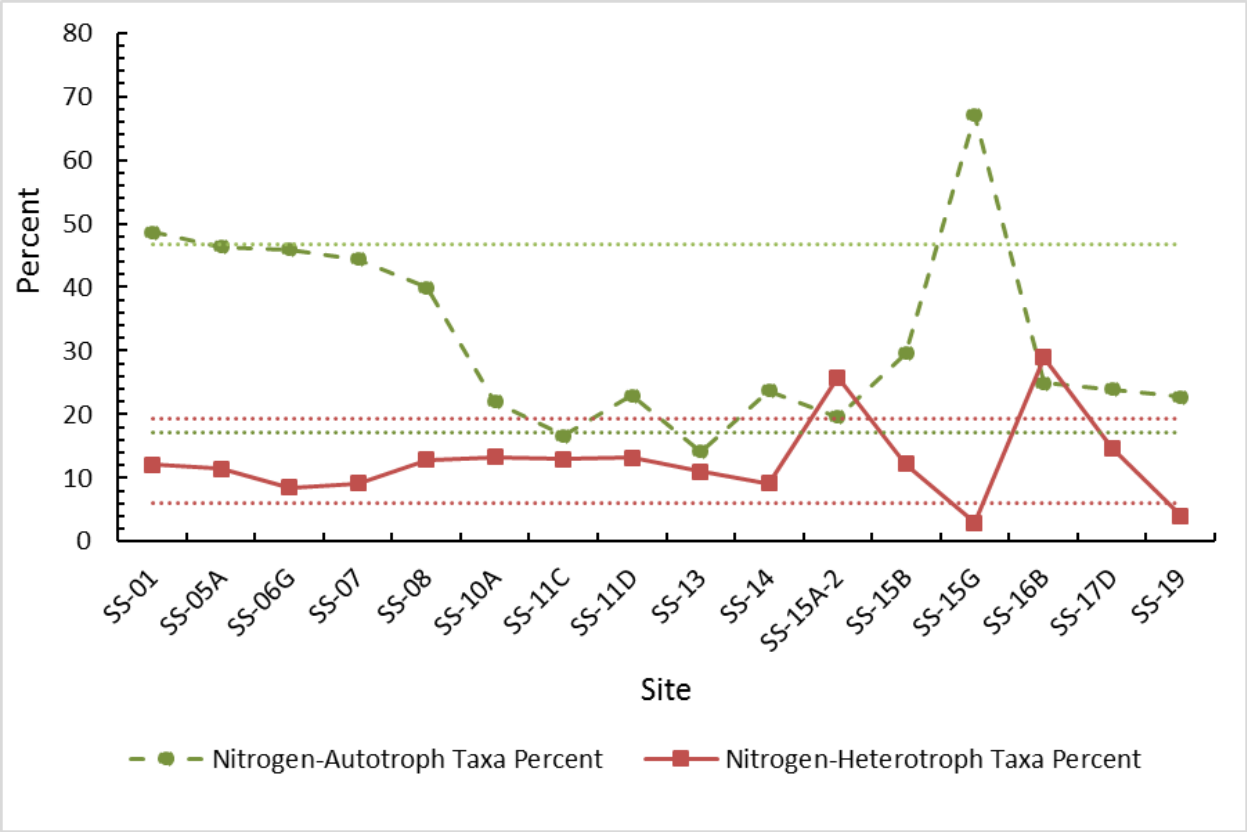

Figure 6-4. Relative abundance of diatoms classified in relation to trophic state (after Van Dam et al. [1994]) in the Silver Bow Creek watershed, 2018. Dotted lines represent (mean +1 standard deviation [SD]) and (mean –1 SD) for respective metrics and are provided as an aid to interpretation.

6.3.2.3.2 Saprobity and Hypoxia

The relative abundance of oligosaprobous or ß-mesosaprobous diatoms [Van Dam et al., 1994] varied between 6.4 percent at Site SS-13 and 62.0 percent at Site SS-15G (Figure 6-5). Mean relative abundance of these taxa was 21.8 percent (SD = 15.1 percent). Site SS-15G was above 1 SD above the mean, whereas Sites SS-13 was 1 SD below the mean. The relative abundance of oligosaprobous or ß-mesosaprobous diatoms remained relatively consistent and high from Sites SS-01 through SS-08, declined and remained relatively consistent from Sites SS-10A through SS-15B, hit its highest value at SS-15G, and then declined again the downstream most sites.

The relative abundance of diatoms with high oxygen demand (continuously high and fairly high oxygen-demand categories based on the classification of Van Dam et al. [1994]) varied between 4.4 percent (Site SS-13) and 30.1 percent (Site SS-01) (Figure 6-5). Mean relative abundance of these taxa was 15.1 percent (SD = 8.0 percent). The relative abundance of these taxa was higher than the mean +1 SD at Sites SS-01 (30.2 percent), SS-05A (24.8 percent) and SS-15G (28.0 percent). Sites SS-11D (7.0 percent) and SS-13 (4.4 percent) both exhibited percentages of low and very low oxygen-demand diatoms below the mean –1 SD. The pattern of

the relative abundance of diatoms with high oxygen demand was very similar to the patterns of the relative abundance of oligosaprobous or ß-mesosaprobous diatoms.

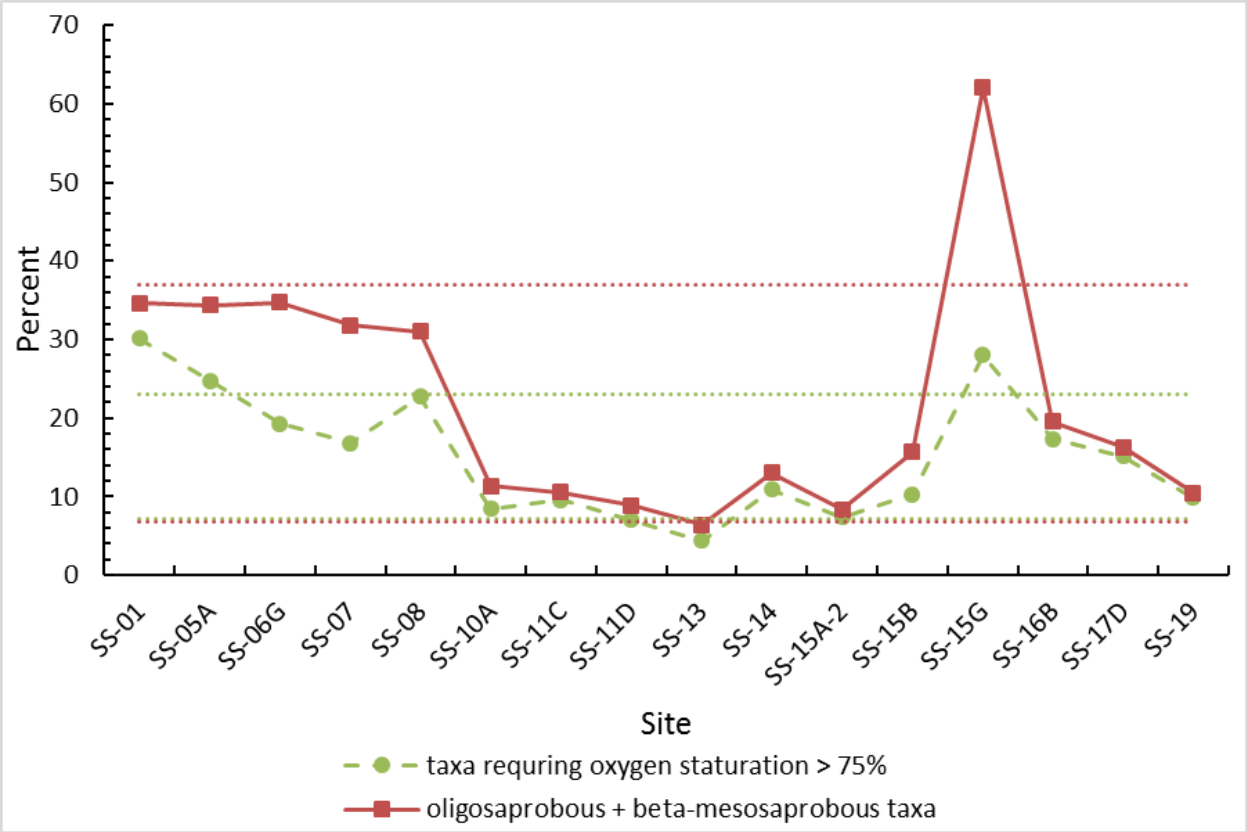

Figure 6-5. The relative abundance oligosaprobous or ß-mesosaprobous diatoms and oxygen-sensitive diatoms (after Van Dam et al. [1994]) in the Silver Bow Creek watershed, 2018. Dotted lines represent (mean +1 standard deviation [SD]) and (mean –1 SD) for respective metrics and are provided as an aid to interpretation.

6.3.3 Ecological Interpretations

6.3.3.1 Site Specific Narratives

6.3.3.1.1 Blacktail Creek at Father Sheehan Park

The taxa that were abundant or common and contributed most to algal biovolume in order of their estimated contributions were: (1) the green alga *Cladophora* (abundant), (2) the diatoms (very abundant), and (3) the blue-green alga *Heteroleibleinia* (very common). *Staurosira construens* v. *binodis* (8.9 percent) was the most abundant diatom followed by *Nitzschia palea* v. *debilis* (8.0 percent) and *Planothidium frequentissimum* (7.4 percent). Both diatom taxa richness (60) and Shannon Diversity (5.02) were high, indicating an even, taxa-rich assemblage (the dominant taxon made up only 8.9 percent of the assemblage) both suggesting good water quality. However, the Pollution Tolerance Index (2.37) indicated minor impairment. The high relative abundance of nitrogen-autotrophs (48.7 percent), the low relative abundance of nitrogen-

heterotrophs (12.1 percent), high relative abundance of diatoms with high oxygen demand (30.1 percent), and the high relative abundance of diatoms intolerant to saprobic conditions (34.6 percent) also suggested good water quality and little impact from nutrient enrichment. The probability of impairment by nutrients, as measured by the relative abundance of nutrient increaser taxa was 56.8 percent. Although the probability of impairment by metals was low (3.9 percent), metals-tolerant taxa made up 20.6 percent of the assemblage suggesting that metals contamination cannot be ruled out here. Fine sediment appeared to have impacted the diatom assemblage. The probability of impairment by fine sediment was 70.0 percent. This assessment was reinforced by the percentages of siltation indicator taxa (44.8 percent, Siltation Index) and of motile and highly motile taxa (25.8 percent), which were both large components of the diatom assemblage.

6.3.3.1.2 Silver Bow Creek above Butte Reduction Works

Ecological conditions at this site were very similar to those of Blacktail Creek at Father Sheehan Park (Site SS-01). The taxa that were abundant or common and contributed most to algal biovolume in order of their estimated contributions were: (1) the green alga *Cladophora* (abundant), *(2)* the diatoms (very abundant), and (3) the blue-green alga *Heteroleibleinia* (very abundant). The three diatom taxa with the highest relative abundances were *Sellaphora atomoides* (9.4 percent), *Nitzschia dissipata* (8.7 percent), and *Nitzschia soratensis* (7.1 percent). Good water quality was suggested by the high diatom taxa richness (58). This contention was supported by the high Shannon Diversity (4.98) and low relative abundance of the dominant diatom (9.4 percent). However, like Site SS-01, the Pollution Tolerance Index (2.37) indicated some minor impairment. The nutrient increaser taxa indicated that the probability of impairment was (56.8 percent). However, little effects from nutrient enrichment were suggested by the high relative abundances of nitrogen-autotrophs (46.4 percent), of diatoms with high oxygen demand (24.8 percent) and diatoms intolerant of saprobic conditions (34.4 percent), and the low relative abundance of nitrogen-heterotrophs (11.5 percent). Although the probability of impairment by metals was low (6.2 percent), metals contamination cannot be ruled out here because metals-tolerant taxa made up 20.5 percent of the assemblage. The probability of impairment by fine sediment was 67.1 percent and motile taxa (26.1 percent) and siltation indicator taxa (50.5 percent) were large components of the diatom assemblage. Mild impairment of the diatom assemblage by fine sediment appeared to have occurred here.

6.3.3.1.3 Silver Bow Creek above Butte WWTP

Again, ecological conditions at this site were very similar to the sites upstream of it: Blacktail Creek at Father Sheehan Park (Site SS-01) and Silver Bow Creek above Butte Reduction Works (Site SS-05A). Like upstream sites, the taxa that were abundant or common and contributed most to algal biovolume in order of their estimated contributions were: (1) the green alga *Cladophora* (abundant), (2) the diatoms (very abundant), and (3) the blue-green alga *Heteroleibleinia* (very abundant). The most common diatom taxa in order of relative abundance in the sample were *Cocconeis placentula* sensu lato (11.9 percent), *Nitzschia soratensis* (8.9 percent), and *Sellaphora atomoides* (8.0 percent). Many characteristics suggested good water quality at this site: diatom taxa richness was 63 (the highest of any site sampled in 2018), the Shannon Diversity Index was

high (4.90), and the percentage of the dominant taxon was low (11.9 percent). However, like upstream sites, the Pollution Tolerance Index (2.39) indicated some minor impairment. Nitrogen-autotrophs (45.9 percent) and oligosaprobous or ß-mesosaprobous diatoms (34.8 percent) were large components of the assemblage. Diatoms with oxygen demand greater than 75 percent (19.3 percent) were a slightly smaller part of the assemblage than at upstream sites. Nitrogen-heterotrophs (8.5 percent) were not a large part of the assemblage. Good water quality and little impact from nutrients were indicated by these characteristics. Like Sites SS-01 and SS-05A, the calculated probability of impairment due to nutrients was 56.9 percent. Metals contamination cannot be ruled out here: although the probability of impairment by metals was low (4.1 percent), metals-tolerant taxa made up 18.4 percent of the assemblage. Impairment by the deposition of fine sediments also appeared to occur here. The probability of impairment by fine sediment was 80.0 percent and siltation taxa (46.3 percent) and motile taxa (21.5 percent) percentages were also relatively high.

6.3.3.1.4 Silver Bow Creek below Butte WWTP

Ecological conditions at this site differed slightly from the sites upstream (Sites SS-01, SS-05A and SS-06G). The taxon that contributed most to algal biovolume was still the green alga *Cladophora* (very common); however, the taxa whose rank contributions to biovolume followed *Cladophora* differed: (2) the chrysophyte genus *Vaucheria* (abundant), (3) the diatoms (abundant), and (4) the green alga *Microspora* (very common). Unlike upstream sites, at Silver Bow Creek below Butte WWTP (Site SS-07) blue-green algae were absent from the benthic assemblage. The three diatom taxa with the highest relative abundances were *Sellaphora atomoides* (18.2 percent), *Cocconeis placentula* sensu lato (12.9 percent), and *Mayamaea permitis* (7.6 percent). Although this site was ranked as excellent based on diatom species richness (52), Shannon Diversity (4.51) and dominant taxon (18.2 percent) suggested slightly diminished conditions: the values for the first 2 metrics were slightly lower and for the third slightly higher than the 3 upstream sites. Minor impairment was suggested by the Pollution Tolerance Index (2.35). Nutrient enrichment seemed to have occurred at this site as the probability of impairment as a result of nutrients was 81.4 percent (the second highest value found in 2018). The relative abundance of nitrogen-autotrophs (44.4 percent), taxa with high oxygen demand (16.8 percent, which was less than Site SS-05A), and taxa that were intolerant of saprobity (31.8 percent) remained high, whereas the relative abundance of nitrogen-heterotrophs (9.2 percent) remained low. Metals-tolerant taxa made up 18.2 percent of the assemblage and this site was only one of two sites where abnormal diatom valves (0.1 percent) were collected, which may indicate some chance of metal contamination at this site. However, the Metals Increasers Taxa Index suggested a low probability of impairment by metals (4.4 percent). Impairment by the deposition of fine sediments also appeared to occur here. Impairment was suggested by the Sediment Increasers Taxa Index (probability of impairment, 95.0 percent, the highest value in 2018), which was supported by the relative abundance of siltation (51.0 percent) and motile taxa (18.7 percent).

6.3.3.1.5 Silver Bow Creek at Rocker

The algal assemblage at Silver Bow Creek at Rocker (Site SS-08) exhibited some similarities to all the upstream sites. Like Sites SS-01, SS-05A and SS-06G, the taxa that were abundant or

common and contributed most to algal biovolume in order of their estimated contributions were: (1) the green alga Cladophora (abundant), (2) the diatoms (very abundant), and (3) the blue-green alga *Heteroleibleinia* (very abundant). However, like at Site SS-07, the chrysophyte genus *Vaucheria* was common and contributed the fourth most to algal biovolume. The 3 diatom taxa with the highest relative abundances were *Sellaphora atomoides* (20.7 percent), *Nitzschia soratensis* (7.9 percent), and *Cocconeis placentula* sensu lato (7.5 percent). Similar to Sites SS-01, SS-05A, and SS-06G, diatom taxa richness (57) was high, whereas Shannon Diversity (4.56) and the relative abundance of the dominant diatom taxon (20.7 percent) were similar to Site SS-07. Slight impairment was suggested by the Pollution Tolerance Index (2.37). Nitrogen-autotrophs (39.9 percent) were a slightly smaller component of the assemblage than at upstream sites. On the other hand, the relative abundances of nitrogen-heterotrophs (12.8 percent) remained low, whereas the percentages of diatoms that were intolerant of low oxygen concentration (22.7 percent), saprobic conditions (31.0 percent) and the probability of impairment by nutrients (77.7 percent) remained high. Like Site SS-07, overall it appeared that mild nutrient contamination occurred here. The probability of impairment by metals was low (4.5 percent) and the relative abundance of metals-tolerant taxa (12.6 percent) was lower than upstream sites, making contamination by metals less likely here. Impairment by the deposition of fine sediments also appeared to occur here. The probability of impairment by fine sediment was 92.0 percent, siltation taxa accounted for 54.0 percent of the assemblage, and motile taxa (18.5 percent) were common.

6.3.3.1.6 Silver Bow Creek above Sand Creek

The algal assemblage made a dramatic change from upstream sites at Site SS-10A. Diatoms were the only significant contributor to algal biovolume. The three diatom taxa with the highest relative abundances were *Nitzschia soratensis* (25.8 percent), *Mayamaea permitis* (15.1 percent), *and Sellaphora atomoides* (13.8 percent). Both diatom taxa richness (42) and Shannon Diversity (3.79) were lower than upstream sites, although both metrics indicated excellent water quality. The decline in Shannon Diversity from Sites SS-07 and SS-08 to SS-10A appeared to be related to the loss of taxa rather than a decrease in assemblage evenness because the contribution of the dominant taxon (25.8 percent) changed little between these sites. The Pollution Tolerance Index (1.96) declined from upstream sites and indicated moderate impairment. The relative abundance of nitrogen-autotrophs (22.0 percent) declined dramatically from upstream sites; however, the relative abundance of nitrogen-heterotrophs (13.3 percent) remained similar to upstream sites. Algae that cannot tolerate low oxygen concentrations (8.5 percent) and saprobic conditions (11.3 percent) also declined from upstream sites. In addition, the probability of impairment by nutrients (61.3 percent) declined slightly from values at Sites SS-07 and SS-08 and was similar to the values found at Site SS-01 through Site SS-06G. These characteristics suggested that water quality was slightly impaired by nutrient enrichment at Site SS-10A. The probability of impairment by metals was low (3.4 percent) and the relative abundance of metals-tolerant taxa (16.4 percent) increased slightly from Site SS-08; however, metals contamination appeared unlikely here. Severe impairment by the deposition of fine sediments also appeared to occur here. The siltation taxa (76.2 percent) suggested severe impairment and the calculated probability of impairment by fine sediment was 80.2 percent. The relative abundance of motile taxa was 16.9 percent.

6.3.3.1.7 Silver Bow Creek above Browns Gulch

The assemblage at Silver Bow Creek above Browns Gulch (Site SS-11C) had some characteristics that were similar to Site SS-10A and some that were similar to sites upstream of Site SS-10A. The taxa that were abundant or common and contributed most to algal biovolume in order of their estimated contributions were: (1) the green alga *Cladophora* (abundant), (2) the chrysophyte genus *Vaucheria* (abundant), (3) the diatoms (abundant) and (4) the blue-green alga *Heteroleibleinia* (very abundant), suggesting that the community "rebounded" to be somewhat similar to sites upstream of Site SS-10A. *Mayamaea permitis* (36.6 percent), *Sellaphora atomoides* (12.6 percent), and *Nitzschia soratensis* (9.3 percent) were the three diatom taxa with the highest relative abundances. Like Site SS-10A, diatom taxa richness (45) and Shannon Diversity (3.51) were somewhat depressed and lower than Sites SS-01 through SS-08, although both rated excellent. In addition, the relative abundance of the dominant diatom taxon (36.6 percent) was high and suggested minor impairment. The Pollution Tolerance Index (1.94) was similar to Site SS-10A and indicated moderate impairment. The relative abundances of nitrogen-autotrophs (16.7 percent), high oxygen-demand taxa (9.6 percent), and oligosaprobous or ß-mesosaprobous diatoms (10.6 percent) were low and similar to Site SS-10A. The relative abundance of nitrogen-heterotrophs (13.0 percent) remained similar to upstream sites. The probability of impairment by nutrients (56.3 percent) declined slightly from Site SS-10A. These metrics suggested that water quality was mildly impaired by nutrient enrichment at this site. The probability of impairment by metals was low (3.8 percent) and the relative abundance of metals-tolerant taxa was 17.1 percent, consequently there was little evidence to support contamination by metals. Impairment by the deposition of fine sediments also appeared to occur here. The siltation taxa (83.8 percent) suggested severe impairment and the probability of impairment by fine sediment was 66.1 percent. The relative abundance of motile taxa was 16.1 percent.

6.3.3.1.8 Silver Bow Creek below Browns Gulch

The taxa that were abundant or common and made up most of the algal biovolume in order of their estimated contributions were: (1) the green alga *Cladophora* (abundant), (2) the diatoms (abundant), and the blue-green algae (3) *Heteroleibleinia* (very abundant) and (4) *Xenococcus* (very abundant). Like Site SS-11C the three diatom taxa with the greatest relative abundances were *Mayamaea permitis* (29.5 percent), *Nitzschia soratensis* (10.5 percent), and *Sellaphora atomoides* (9.5 percent). Both diatom taxa richness (53) and Shannon Diversity (3.95) increased slightly over the values at sites Sites SS-10A and SS-11C. These characteristics suggested excellent conditions, although the relative abundance of the dominant diatom taxon (29.5 percent) and the Pollution Tolerance Index (2.03) both indicated minor impairment. The nutrient increaser metric suggested that the probability of impairment by nutrients was 50.7 percent. Other nutrient-related characteristics were similar to Sites SS-10A and SS-11C (nitrogen-autotrophs (23.0 percent), high oxygen-demand taxa (7.0 percent), nitrogen-heterotrophs (13.2 percent), oligosaprobous or ß-mesosaprobous diatoms (8.9 percent)) suggesting that some nutrient enrichment occurred at this site. The probability of impairment by metals was low (3.4 percent); however, the relative abundance of metals-tolerant taxa increased to 26.5 percent, thus, impairment by metals cannot be ruled out here. Impairment by the deposition of fine sediments also appeared to occur here. The probability of impairment by fine sediment was 67.8 percent and

the siltation taxa abundance (76.0 percent) suggested severe impairment. The relative abundance of motile taxa was 16.9 percent.

6.3.3.1.9 Silver Bow Creek in Reach L

Common non-diatom algal taxa at this site, in order of their contribution to algal biovolume, were the green alga *Cladophora* (abundant), the diatoms (very abundant), the blue-green algae *Heteroleibleinia* (very abundant), and *Xenococcus* (very abundant). *Mayamaea permitis* (39.8 percent), *Nitzschia soratensis* (12.1 percent), and *Nitzschia palea* v. *debilis* (9.4 percent) were the three dominant diatom taxa. Taxa richness (39) and Shannon Diversity (3.26) were lower than any site upstream of Site SS-13 although their levels did not indicate impairment. However, the Pollution Tolerance Index (2.08) and the relative abundance of the dominant diatom taxon (39.8 percent) both indicated minor impairment. Although the relative abundance of nitrogen-heterotrophic taxa was similar to upstream sites (11.0 percent), the relative abundance of nitrogen-autotrophs (14.1 percent), high oxygen-demand taxa (4.4 percent), and oligosaprobous or ß-mesosaprobous diatoms (6.4 percent) were the lowest of any site sampled in 2018. The proportion of nutrient increasers in the assemblage indicated that the probability of impairment by nutrients was 37.1 percent. Given these characteristics, slight impairment by nutrients was suggested. Metals contamination cannot be ruled out here: although the probability of impairment by metals was only 3.5 percent, metals-tolerant taxa made up 24.8 percent of the assemblage. Moderate impairment of the flora by fine sediment may be indicated here because the assemblage was strongly dominated by siltation taxa (85.4 percent) and the probability of impairment by fine sediment was 45.0 percent. Motile taxa made up 13.2 percent of the assemblage

6.3.3.1.10 Silver Bow Creek at Miles Crossing

Like other sites on Silver Bow Creek, the taxa that were abundant or common and made up most of the algal biovolume in order of their estimated contributions were: (1) the green alga *Cladophora* (very common), (2) the diatoms (abundant) and (3) the blue-green alga *Heteroleibleinia* (very abundant). The three most abundant diatom taxa were *Mayamaea permitis* (30.0 percent), *Nitzschia soratensis* (14.4 percent), and *Sellaphora atomoides* (9.7 percent). Taxa richness (48) and Shannon Diversity (3.79) rebounded somewhat compared to Site SS-13 and the sites were rated as in excellent condition by these metrics. However, like Site SS-13, the Pollution Tolerance Index (2.15) and the relative abundance of the dominant diatom taxon (30.0 percent) both indicated minor impairment. The relative abundance of nitrogen-autotrophs (23.7 percent), high oxygen-demand taxa (10.9 percent), and oligosaprobous or ß-mesosaprobous diatoms (13.0 percent) all increased over their low values at Site SS-13. the proportion of nutrient increasers in the assemblage indicated that the probability of impairment by nutrients declined to 51.8 percent. The relative abundance of nitrogen-heterotrophic taxa (9.0 percent) was similar to upstream sites. Given these characteristics, slight impairment by nutrients was suggested. Metals contamination cannot be ruled out here because metals-tolerant taxa made up 19.4 percent of the assemblage although the probability of impairment by metals was only 3.9 percent. Fine sediment may have impacted the diatom assemblages as the Siltation Index (76.5 percent) indicated moderate

impairment by fine sediment, motile diatom taxa made up 16.2 percent of the assemblage: however, the probability of impairment by fine sediment was 75.7 percent.

6.3.3.1.11 Silver Bow Creek above German Gulch (Alternate Site)

The overall algal assemblage changed slightly at Site SS-15A-2: the taxa that were abundant or common and contributed most to algal biovolume in order of their estimated contributions were: (1) the chrysophyte *Vaucheria* (abundant), the green algae (2) *Cladophora* (abundant) and (3) *Ulva* (abundant), (4) the diatoms (very abundant) and (5) the blue-green alga *Heteroleibleinia* (very abundant). *Mayamaea permitis* (24.4 percent), *Nitzschia paleacea* (16.2 percent), and *Sellaphora atomoides* (9.8 percent) were the three diatom taxa that contributed most to the assemblage. Taxa richness (47) and Shannon Diversity (3.88) were similar to Site SS-14; however, the Pollution Tolerance Index (1.97) was below the threshold of 2.01 and thus moderate impairment was indicated. The relative abundance of the dominant diatom taxon (24.4 percent) indicated no impairment. The relative abundance of nitrogen-autotrophs (19.7 percent), high oxygen-demand taxa (7.3 percent), and oligosaprobous or ß-mesosaprobous diatoms (8.3 percent) all decreased and nitrogen-heterotrophic taxa (25.8 percent) increased over their values at Site SS-14. In addition, the proportion of nutrient increasers in the assemblage indicated that the probability of impairment by nutrients declined to 45.8 percent. Mild impairment by nutrients was suggested. Metals contamination seemed to have occurred here as metals-tolerant taxa made up 39.6 percent of the assemblage although the probability of impairment by metals was only 4.1 percent. Fine sediment may have impacted the diatom assemblages as the Siltation Index (77.1 percent) indicated severe impairment by fine sediment and motile diatom taxa made up 26.5 percent of the assemblage. The probability of impairment by fine sediment was 46.8 percent.

6.3.3.1.12 German Gulch near confluence

The taxa that were abundant or common and made up most of the algal biovolume in order of their estimated contributions were: (1) the blue-green alga *Nostoc* (very abundant), (2) the green algae (2) *Ulva* (abundant) and (3) *Cladophora* (abundant), (4) the diatoms (very abundant) and (5) the blue-green alga *Heteroleibleinia* (very abundant). *Cocconeis placentula* sensu lato (29.5 percent), *Navicula reichardtiana* (8.4 percent), and *Nitzschia dissipata* (7.5 percent) were the most common diatom taxa. Diatom taxa richness was 43 and Shannon Diversity was 4.09. The Pollution Index (2.66) was the highest of any site sampled in 2018 and indicated excellent conditions, but the relative abundance of the dominant diatom taxon (29.5 percent) suggested mild impairment. Of all the sites evaluated in 2018, this site exhibited the highest relative abundance of nitrogen-autotrophs (67.0 percent), whereas the relative abundance of the nitrogen-heterotrophs (3.0 percent) had the lowest value. In addition, high oxygen-demand taxa (28.0 percent, the second highest value in 2018) and oligosaprobous or ß-mesosaprobous diatoms (62.0 percent, the highest value in 2018) were high. The calculated probability of impairment by nutrients was 25.9 percent (the lowest value in 2018) thus, there was little evidence to conclude that nutrients negatively influenced the water quality here. Metals contamination appeared unlikely at Site SS-15G: metals-tolerant taxa made up only 9.9 percent of the assemblage and the probability of impairment by metals was only 4.4 percent. The Siltation Index (32.1 percent) indicated minor impairment by fine sediment; however, motile diatom taxa made up 33.8 percent

of the assemblage and the probability of impairment by fine sediment was 48.5 percent. Thus, fine sediment appeared to slightly influence the diatoms at this site.

6.3.3.1.13 Silver Bow Creek below German Gulch

The green algae (1) *Oedogonium* (abundant) and (2) *Cladophora* (abundant), (3) the diatoms (abundant) and (4) the blue-green alga *Heteroleibleinia* (very abundant) made the greatest contributions to algal biovolume. The three most abundant diatom taxa were *Mayamaea permitis* (24.4 percent), *Nitzschia soratensis* (9.1 percent), and *Sellaphora atomoides* (7.8 percent). Diatom taxa richness (55) and Shannon Diversity (4.27) increased to values found in the upstream-most sites (Sites SS-01 to SS-08). The Pollution Tolerance Index (2.13) indicated minor impairment, whereas the relative abundance of the dominant diatom taxon (24.4 percent) indicated no impairment. The relative abundance of nitrogen-autotrophs (29.6 percent), high oxygen-demand taxa (10.3 percent), and oligosaprobous or ß-mesosaprobous diatoms (15.6 percent) all increased over their low values at Site SS-15A-2 and the relative abundance of nitrogen-heterotrophic taxa (12.3 percent) was similar to sites upstream of Site SS-15A-2. The probability of impairment by nutrients (46.2 percent) was similar to Site SS-15A-2. Given these characteristics, slight impairment by nutrients was suggested. Metals contamination seemed to have occurred here as metals-tolerant taxa made up 30.6 percent of the assemblage; however, the probability of impairment by metals was only 4.6 percent. Fine sediment may have impacted the diatom assemblages as the Siltation Index (70.3 percent) indicated severe impairment by fine sediment, motile diatom taxa made up 20.5 percent of the assemblage, and the probability of impairment by fine sediment was 55.9 percent.

6.3.3.1.14 Silver Bow Creek in Reach P near Fairmont

The most common algae, ranked in order of their dominance of the algal biovolume at Site SS-16, were (1) the cyanophyte *Leptolyngbya* (very abundant), (2) the chlorophyte *Ulva* (abundant) and (3) the diatoms (very abundant). The most common diatom taxa were *Mayamaea permitis* (28.1 percent), *Nitzschia paleacea* (24.3 percent), and *Nitzschia fonticola* (10.0 percent). Diatom taxa richness (34) was the lowest of any site in 2018 and Shannon Diversity (3.38) was also comparatively low; however, both rated the site as unimpaired. Both the Pollution Tolerance Index (2.27) and the relative abundance of the dominant diatom taxon (28.1 percent) indicated mild impairment. The relative abundance of nitrogen-heterotrophic taxa (28.9 percent) was the highest of any site sampled in 2018. The relative abundance of nitrogen-autotrophs (24.9 percent), high oxygen-demand taxa (17.3 percent), and oligosaprobous or ß-mesosaprobous diatoms (19.6 percent) as well as the calculated probability of impairment by nutrients (50.9 percent) were similar to Site SS-15B. Given these characteristics, slight impairment by nutrients was suggested. Impairment by metals seemed likely here: metals-tolerant taxa made up 34.7 percent of the diatom assemblage, the probability of impairment by metals was 12.9 percent (the highest value recorded in 2018). In addition, the diatom sample from this site included abnormal diatom valves (0.1 percent). Fine sediment may have impacted the diatom assemblages as the Siltation Index (87.0 percent) indicated severe impairment by fine sediment and motile diatom taxa made up 44.3 percent of the assemblage; however, the probability of impairment by fine sediment was only 27.5 percent (the lowest value of any site in 2018).

6.3.3.1.15 Silver Bow Creek below Stewart St at Opportunity

The algal assemblage made a change from most upstream sites at Site SS-17D: only diatoms (rank 1, abundant) and the chlorophyte *Stigeoclonium* (rank 2, very common) were collected. However, the diatom assemblage was dominated by taxa that were also abundant at other sites, including *Nitzschia soratensis* (27.5 percent), *Mayamaea permitis* (14.7 percent) and *Sellaphora atomoides* (13.8 percent). Both diatom taxa richness (37) and Shannon diversity (3.59) suggested good water quality; however, both were lower than many upstream sites. The relative abundance of the most common diatom taxon (27.5 percent) and the Pollution Tolerance Index (2.28) indicated mild impairment at this site. The relative abundance of nitrogen-autotrophs (24.0 percent), high oxygen-demand taxa (15.2 percent), and oligosaprobous or ß-mesosaprobous diatoms (16.3 percent) were very similar to Site SS-16B. However, the relative abundance of nitrogen-heterotrophs (14.7 percent) was lower than at Site SS-16B and probability of impairment by nutrients (65.1 percent) was higher than Site SS-16B. It appeared that this site was slightly impaired by nutrients. Impairment by metals cannot be ruled out here: metals-tolerant taxa made up 21.8 percent of the diatom assemblage and the probability of impairment by metals was 8.1 percent. The Siltation Index (81.8 percent) indicated severe impairment by fine sediment and motile diatom taxa made up 29.7 percent of the assemblage. In addition, the probability of impairment by fine sediment (66.3 percent) increased dramatically over Site SS-16B. Fine sediment appeared to influence the diatoms at this site.

6.3.3.1.16 Silver Bow Creek at Frontage Road

At Site SS-19, the most common algae, ranked in order of their dominance of the algal biovolume, were (1) the chlorophyte *Ulva* (very abundant), (2) the diatoms (very abundant), (3) the chlorophyte *Stigeoclonium* (very abundant), and the cyanophyte *Homoeothrix* (very common). The three most common diatoms were *Sellaphora atomoides* (28.1 percent), *Mayamaea permitis* (22.2 percent), and *Nitzschia soratensis* (18.6 percent). Like Site SS-17D, both diatom taxa richness (37) and Shannon diversity (3.27) suggested excellent water quality; however, both were lower than many upstream sites and the relative abundance of the most common diatom taxon (28.1 percent) and the Pollution Tolerance Index (2.20) indicated mild impairment. The relative abundance of nitrogen-autotrophs (22.7 percent) was similar to Site SS-17D; however, high oxygen-demand taxa (9.9 percent) and oligosaprobous or ß-mesosaprobous diatoms (10.5 percent) were lower than at Site SS-17D and the probability of impairment by nutrients (88.0 percent) was the highest of any site in 2018. It appeared that this site was moderately impaired by nutrients. Impairment by metals appeared to be unlikely here: metals-tolerant taxa made up 13.6 percent of the diatom assemblage and the probability of impairment by metals was 5.4 percent. Fine sediment appeared to influence the diatoms at this site. The Siltation Index (81.2 percent) indicated severe impairment and the calculated probability of impairment by fine sediment was 94.1 percent (the second highest value in 2018). However, motile diatom taxa made up only 13.9 percent of the assemblage.

Table 6-4. Summary of potential stressors in the Silver Bow Creek watershed based on the narrative interpretations. September 17-21, 2018.

(blank) No impairment suggested.

? Overall evidence suggested some impairment, but the evidence was inconclusive.

\+ Overall evidence suggested minor impairment.

++ Overall evidence suggested moderate impairment.

+++ Overall evidence suggested severe impairment.

6.4 DISCUSSION

All sites were assessed as in either “good” or “excellent” condition based on the overall Biological Integrity Score in Table 6-3. This score was based on the combination of the all metrics in Table 6-3. However, individual metrics did detect impairment. Some diatom metrics that detected more general impairment (Diatom Species Richness, Shannon Diversity, Disturbance Index) rated all sites as unimpaired. However, the Pollution Index indicated that all sites, except Site SS-15G, were mild to moderately impaired. In addition, the relative abundance of the Dominant Taxon metric indicated mildly impaired conditions at all sites downstream of and including Site SS-10A, except Sites SS-15A-2 and SS-15B, for which the scores were very close to the cutoff for impairment.

Specific stressors included nutrients, fine sediment and metals. Based on our interpretation of the nutrient metrics (relative abundances of nitrogen-autotrophs, nitrogen-heterotrophs, high oxygen-demand taxa, and oligosaprobous or ß-mesosaprobous diatoms and the probability of impairment by nutrients) 12 sites were impaired (all sites on Silver Bow Creek downstream of

and including Site SS-07). Based on our interpretation of the diatom metrics associated with fine sediment (Siltation Index, relative abundance of motile taxa, and probability of impairment as a result of fine sediment) all sites were mildly, moderately or severely impaired. Impairment by metals (metrics included relative abundance of metals-tolerant taxa, abnormal cell valves, and probability of impairment by metals) could not be ruled out at Sites SS-01 through SS-07, SS-11D through SS-14, and SS-17D). Mild metals contamination was suggested at Sites SS-15A-2, SS-15B, and SS-16B.

7.0 FISH[57]

7.1 INTRODUCTION

The Upper Clark Fork River (UCFR) was subject to extensive mining and mineral processing activities during the late 19th and early 20th centuries. Metal contamination from these activities have reduced habitat quality and altered the fishery in the UCFR. Fishery changes include reduced trout numbers and changes in species composition. Because of these negative impacts, angling use of the Clark Fork River is lower than other streams in western Montana. Extensive remediation and restoration efforts are under way and these efforts aim to mitigate historical mining and smelting damage to natural resources in the Upper Clark Fork River Basin (UCFRB). Effects of these actions have been dramatic in Silver Bow Creek, where completed remedial activities have allowed the return of fish to a river where fish were extirpated for more than a century [Naughton, 2013]. The Silver Bow Creek fishery will continue to change in response to improvements in water quality, maturation of riparian vegetation, natural changes in river morphology, tributary restoration projects, flow enhancement, and other factors. Remedial efforts on the mainstem of the Clark Fork River are more recent and the area slated for restoration projects is vast (see Saffel et al. [2018]). Thus, monitoring fisheries responses to restoration needs to be done at multiple spatial and temporal scales [Geum Environmental, 2015]. This monitoring program evaluates the UCFRB remediation program at the basin (mainstem river), watershed (i.e., individual tributaries), and project (site) scales.

In the past, fisheries data collection was conducted sporadically in the UCFRB. From 2008 to 2010, Montana Fish, Wildlife & Parks (FWP) biologists established long-term monitoring sections on the mainstem UCFR. FWP has completed population estimates in these sections each of the subsequent years. These mainstem population surveys provide a dataset that can be used to evaluate the mainstem Clark Fork River fishery before, during, and after restoration and remediation actions. Annual fisheries surveys in Silver Bow Creek began on 2013. Silver Bow Creek surveys initially consisted of one-pass electrofishing conducted in the fall at four sections. In 2014, two more sections were added and sampling occurred in spring and fall. In 2015, the first fish population estimates were attempted on Silver Bow Creek, both in spring and fall. The spring sampling was shifted to summer from 2016-2018 and population estimates are now attempted summer and fall at six sections. The summer sampling is conducted during the period of low flows and high water temperatures. Low dissolved oxygen has been documented in the past during the summer and hypoxic areas of Sliver Bow Creek tend to be devoid of trout during this period [Naughton, 2013]. Fall sampling is focused on evaluating fish numbers and distribution when water temperatures have cooled and dissolved oxygen concentrations are more favorable to fish.

[57] Chapter 7 was prepared by N. Cook and T. Elam with Montana Fish, Wildlife & Parks (Missoula, Montana) with minor editing and formatting by RESPEC.

7.2 METHODS

Silver Bow Creek was sampled at six sections using backpack electrofishing. Two or three pass depletion estimates [Zippin, 1958] were conducted when enough numbers of fish were captured on the first pass and numbers of a particular species declined in subsequent electrofishing passes. Flows in Silver Bow Creek during the 2018 August sampling were about double the average, which made it difficult to efficiently capture fish. Flows remained high throughout the fall and were about 1.5 times the average flow during the October sampling. Therefore, population estimates and catch-per-unit-effort (CPUE) data for 2018 should be interpreted with caution.

7.3 RESULTS

For the summer sampling, population estimates could be generated in all sections except Rocker (Table 7-1). Summer Westslope Cutthroat Trout densities were estimated to be 3 fish/100 m at Fairmont, 11 fish/100 m at German Gulch, and 3 fish/100 m at Ramsay. From 2015-2018, summer Westslope Cutthroat Trout estimates averaged 9 fish/100 m (standard deviation [SD] = 8.5) at Fairmont, 11 fish/100 m at German Gulch, and 5 fish/100 m (SD = 2.1) at Ramsay (Figure 7-3). Brook Trout were estimated at 2 fish/100 m at Fairmont, 6 fish/100 m at German Gulch, and 3 fish/100 m at LAO. From 2015-2018, summer Brook Trout estimates averaged 13 fish/100 m (SD = 9.7) at Fairmont and 6 fish/100 m (SD = 1.5) at German Gulch. During fall sampling, estimates were generated for Fairmont, German Gulch, and Ramsay (Table 7-2). Fall Westslope Cutthroat Trout densities were estimated to be 5 fish/100 m at Fairmont, 3 fish/100 m at German Gulch, and 6 fish/100 m at Ramsay. From 2015-2018, fall Westslope Cutthroat Trout estimates averaged 6 fish/100 m (SD = 2.9) at Fairmont, 4 fish/100 m (SD = 2.2) at German Gulch, and 4 fish/100 m (SD = 1.8) at Ramsay (Figure 7-4). Brook Trout were estimated at 2 fish/100 m at German Gulch, 2 fish/100 m at Ramsay, and 3 fish/100 m at LAO in the fall estimates.

7.4 DISCUSSION

The Fairmont and Below German Gulch Sections support the highest densities of Westslope Cutthroat Trout in Silver Bow Creek during the summer. During fall sampling, Westslope Cutthroat Trout were present in the Ramsay Section in numbers similar to Below German Gulch and Fairmont. Naughton [2013] found that Westslope Cutthroat Trout in Silver Bow Creek dispersed in the fall from the area around German Gulch into other areas. This dispersal is facilitated by lower water temperatures and increases in dissolved oxygen

in the fall months. It appears that the distribution of the Silver Bow Creek Westslope Cutthroat Trout population is centered around German Gulch and expands upstream to Ramsay during the cooler months. Individual Westslope Cutthroat Trout are occasionally caught in other Silver Bow Sections (i.e., Highway 1, Rocker, and LAO), but Westslope Cutthroat Trout have yet to establish a true population in these areas. Westslope Cutthroat Trout have also been captured in another Silver Bow Creek sampling section. This section, not sampled in 2018, is located near Father Sheehan Park in the city of Butte. Westslope Cutthroat Trout from the Father Sheehan Section are thought to be from Blacktail Creek, which is another potential source of Westslope Cutthroat Trout recruitment for Silver Bow Creek (J. Lindstrom, FWP, *personal communication*).

8.0 GEOMORPHOLOGY

8.1 INTRODUCTION

Geomorphology was monitored in Subareas 2, 3, and 4 of the Streamside Tailings Operable Unit (SSTOU) in 2018 to evaluate conditions in the stream channel compared to project reference values and to assess potential ongoing maintenance needs. Monitoring is conducted at each site five and ten years after remediation was completed. In 2018, monitoring was conducted at seven sites: three Subarea 2 sites, two Subarea 3 sites, and two Subarea 4 sites (Figure 8-1). In the Subarea 2 sites, monitoring was conducted for the second time and represents conditions ten years after remediation. At the Subarea 3 and 4 sites, monitoring was conducted for the first time and represents conditions five years after remediation. Specific parameters at each site were compared to geomorphic reference values as described in the long-term monitoring plan for Silver Bow Creek [DEQ and NRDP, 2004].

8.2 METHODS

The sampling methods employed in this evaluation were established in an early version of the SSTOU monitoring plan [DEQ and NRDP, 2004] and are described in the 2018 update to the project sampling and analysis plan [RESPEC, 2018b]. These methods were largely derived from components of the environmental monitoring and assessment program (EMAP) protocols developed by the U.S. Environmental Protection Agency to evaluate wadeable streams [Peck et al., 2001].

8.2.1 Monitoring Locations

Monitoring was conducted at seven Silver Bow Creek sites in 2018 (Figure 8-1). At each site, a 1,000-foot reach was established and geomorphic channel characteristics were described within each 1000-foot reach. Monitoring sites were generally extended downstream from the surface water sampling site in accordance with project precedents [DEQ and NRDP, 2004]. However, deviations from this protocol were made at some sites to avoid particular obstacles. The monitoring reaches at Sites SS-13, SS-15B, and SS-19 were extended upstream from the surface water sample sites to avoid obstacles; specifically a road culvert and railroad bridge located downstream from Site SS-13, the German Gulch tributary confluence downstream from Site SS-15A-2, and a local roadway (Frontage Road) and highway (Interstate 90) downstream from Site SS-19. The monitoring reach downstream from Site SS-15B was reduced to 637 feet because in that reach the stream enters a narrow, hazardous channel tightly constrained by railroad and roadway grades.

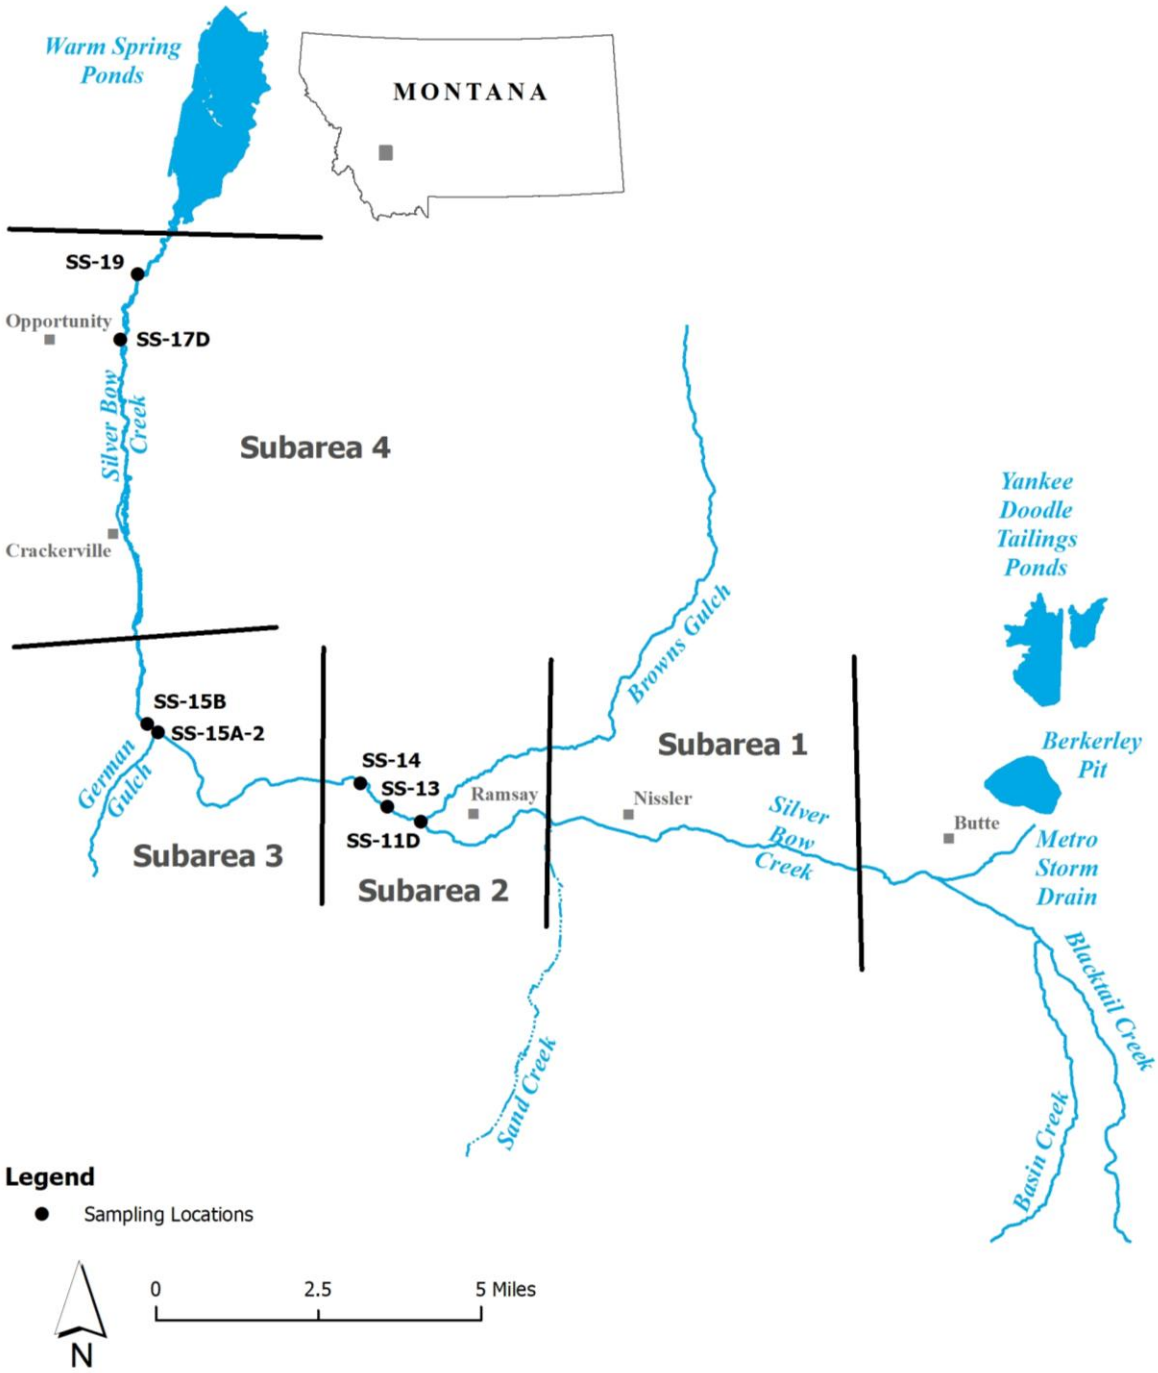

Figure 8-1. Geomorphic monitoring reaches and remedial Subareas in the Streamside Tailings Operable Unit, 2018.

8.2.2 Monitoring Schedule

Geomorphic monitoring occurs at each monitoring site initially after five years have elapsed since remediation was completed and again after ten years [DEQ and NRDP, 2004]. Monitoring has now been conducted in all SSTOU sites (Table 8-1). Monitoring in 2018 was conducted for the second time (i.e., ten year post-remediation monitoring) in the Subarea 2 sites (Sites SS-11D, SS-13, and SS-14) and for the first time (i.e., five year post-remediation monitoring) in the Subarea 2 and 3 sites (Sites SS-15A-2, SS-15B, SS-17D, and SS-19) (Table 8-1). In 2018, field data was collected from September 5-6, 2018.

Table 8-1. Geomorphic monitoring schedule for the Streamside Tailings Operable Unit. Sites are to be monitored at five year intervals after remediation has been completed in each associated reach [DEQ and NRDP, 2004][62].

Subarea	Reach	Sites within Reach	Year remedy completed	Monitoring Scheduled		Monitoring Occurred		Monitored in 2018
				5-Year	10-Year	5-Year	10-Year	
1	A	SS-07	2003	2008	2013	-	2013	
	B	SS-08	2003	2008	2013	2007	2013	
	E	SS-10A	2003	2008	2013	2009	2014	
2	F	SS-10B	2004	2009	2014	2009	2014	
	H	SS-11C	2006	2011	2016	2011	2016	
	I	SS-11D	2008	2013	2018	2012	2018	X

3	M	SS-15A	2013	2018	2023	2018		X
		SS-15B	2013	2018	2023	2018		X
4	P	SS-16B	2010	2016	2021	2016		
	T	SS-17D	2013	2018	2023	2018		X
		SS-19	2013	2018	2023	2018		X

8.2.3 Monitoring Parameters

Geomorphic monitoring metrics and reference values for those metrics are described in Table 8-2. The monitoring metrics include assessments of pool availability; channel morphology; and the availability of overhead cover for aquatic animals as provided by undercut banks, the riparian canopy, streamside vegetation, and instream wood.

[62] Some SSTOU monitoring sites (Sites SS-01, SS-05A, SS-06G, and SS-15G) are monitored for other environmental media (e.g., surface water) but these sites are located outside the SSTOU. Geomorphology will not be monitored at those sites unless requested by DEQ.

Table 8-2. Reference value for geomorphic monitoring metrics in the Streamside Tailings Operable Unit following remediation.

Monitoring Metric	Year (post-remediation)	
	5	10
Percent pools (%)	20-50	20-50
Average width to depth ratio	8-14	8-14
Undercut banks (%)	8-20	8-20
Riparian cover; overstory (>5 m) canopy (%)	45-65	45-65
Channel cover (%)	15-35	15-35
Woody debris (%)	15-35	15-35

8.2.4 Sample Collection and Analysis

8.2.4.1 Percent Pools

At each monitoring site, a longitudinal profile (approximately 1,000 feet length) of the stream bottom at the channel thalweg was surveyed using a survey grade GPS (accuracy ±3 cm). Maximum spacing between survey points (i.e., spatial coordinates including latitude, longitude, and elevation) was 100 feet. Points were spaced more closely where the channel curved, where secondary channels occurred, at substantial slope inflection points within the channel, and at changes in instream habitat features. Instream habitat features were identified visually and describe the geomorphic channel unit character of the stream (i.e., riffle, run, or pool). The proportion of pool habitat (at the channel thalweg) within the overall 1,000 foot thalweg length of the entire survey section was calculated from data collected in the longitudinal profile.

8.2.4.2 Width to Depth Ratio

Channel cross-sections were surveyed at 100 foot intervals (11 cross-sections total including the upstream and downstream end of the survey section) using a survey grade GPS. Cross-sections were labeled A through K starting at the upstream end of each monitoring site. For each cross-section, at least ten points were surveyed within the bankfull channel, including points at the bankfull channel margin, water edge, thalweg, and all substantial slope inflection points within the channel. For each channel cross-section surveyed, the bankfull width and mean bankfull depth were determined and the channel width to depth ratio (the quotient of the bankfull width and mean bankfull depth) was calculated. Cross-sections and longitudinal profiles for each site monitored in 2018 are displayed: SS-11D (Figure 8-2), SS-13 (Figure 8-3), SS-14 (Figure 8-4), SS-15A-2 (Figure 8-5), SS-15B (Figure 8-6), SS-17D (Figure 8-7), and SS-19 (Figure 8-8).

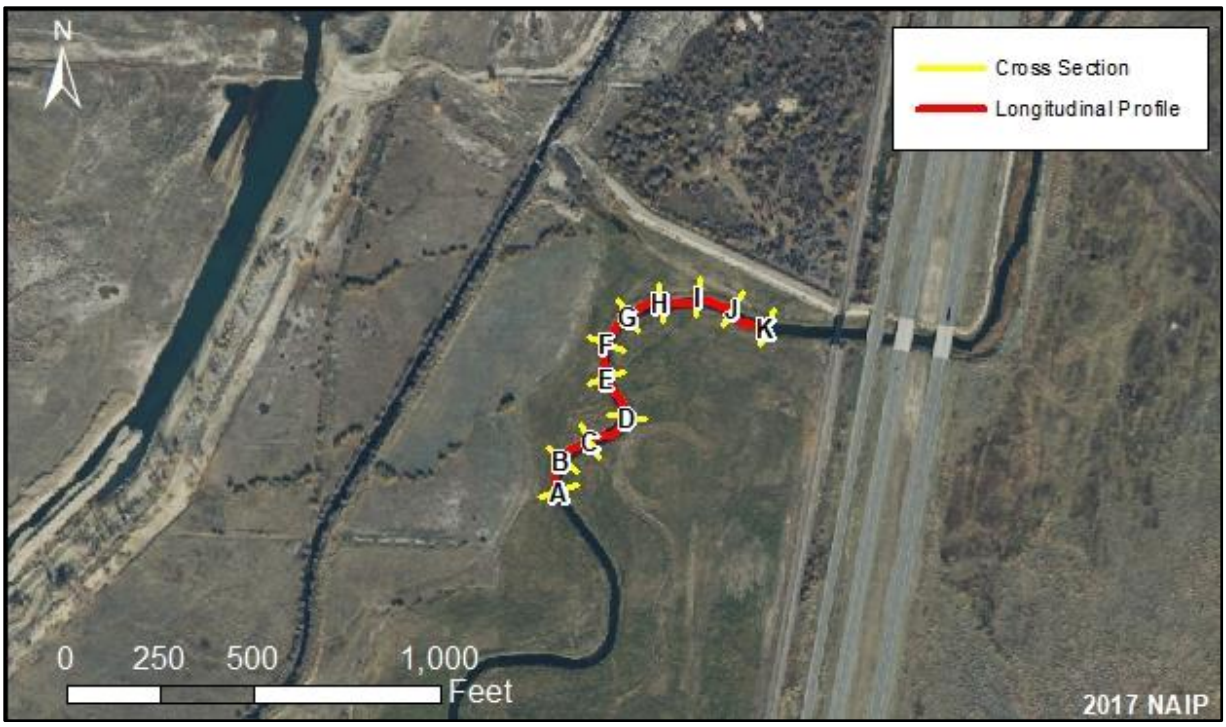

Figure 8-8. Geomorphic monitoring at Site SS-19 (Silver Bow Creek at Frontage Road) in the Streamside Tailings Operable Unit, 2018.

8.2.4.3 Undercut Banks

At each cross-section transect, the areal cover of undercut banks was determined by measuring the length and depth of undercut banks along 15 feet to either side of the cross section intersection with each bank. Thus, 30 feet of streambank were evaluated on river right and 30 feet of streambank were evaluated on river left at each transect. The total length of streambank surveyed was 660 feet, and the number of discrete survey sections along the streambank was 22 for each reach.

8.2.4.4 Riparian Cover

The proportion of areal cover provided by riparian vegetation was estimated visually in 22 discrete monitoring plots (plot area = 900 square feet) in each monitoring reach. Areal cover over the floodplain was estimated for three types of riparian vegetation: ground (annual vegetation; <0.5m), understory (shrubs and willows; 0.5-5 m), and overstory (trees not including willows; >5 m). Square sample plots were located along the streambanks, centered at each cross-section transect, and extending 30 feet back from the streambanks.

8.2.4.5 Channel Cover

At each of the 11 cross-section transects, the areal cover of overhanging vegetation was measured using a spherical densiometer [Peck et al., 2001]. Six measurements were taken at each

of the 11 river transects including measurements at the wetted edge of the right and left banks, and four measurements at the center of stream channel at a height of 1-foot above the surface of the stream. Measurements at the center of the stream channel were made facing upstream, toward the left bank, toward the right bank, and downstream [Peck et al., 2001].

8.2.4.6 Woody Debris

At each of the 11 cross-section transects, the percent of stream channel cover provided by woody debris was estimated within an area extending 15 feet to either side of the cross section along both banks and extending the full width of the stream. Woody debris was defined as having a diameter at least four inches and a length at least five feet [Peck et al., 2001].

8.2.5 Data Analysis

For the monitoring metrics described at each of the cross-section transects (i.e., width to depth ratio, undercut banks, overstory canopy cover, overhanging vegetation, and woody debris cover), the mean of all measurements was compared to the reference value (Table 8-2). The percent of pool habitat was calculated as the proportion of pool length to total channel length within each section.

8.3 RESULTS

8.3.1 Percent Pools

Pools were identified by depressions in the longitudinal profiles from each surveyed reach. Identified pools for each reach are depicted in the longitudinal profiles for Subarea 2 sites (Figure 8-9), Subarea 3 sites (Figure 8-10), and Subarea 4 sites (Figure 8-11). The total length of all pools within each reach was then determined and the proportion of all pools within the reach was determined as the percent pools metric.

In the Subarea 2 sites, pool proportions were 44 percent, 61 percent, and 69 percent in Sites SS-11D, SS-13, and SS-14, respectively (Table 8-3). Site SS-11D was within the reference range (20-50 percent) but the other two Subarea 2 sites were above that range. Three pools were observed in Sites SS-11D and SS-13 and five pools were identified at Site SS-14 (Figure 8-9).

In the Subarea 3 sites, pool proportions were 9 percent and 15 percent in Sites SS-15A-2 and SS-15B, respectively (Table 8-3). Both sites were below the reference range. One pool was observed in Site SS-15A-2 and two pools were observed in Site SS-15B (Figure 8-10).

In the Subarea 4 sites, pool proportions were 45 percent and 63 percent in Sites SS-17D and SS-19, respectively (Table 8-3). Site SS-17D was within the reference range and site SS-19 was above the reference range. At each site, six pools were observed (Figure 8-11).

Table 8-3. Feature lengths in each monitoring reach of the Streamside Tailings Operable Unit, 2018.

Subarea	Monitoring Reach	Length (feet)		Pool Proportion (%)
		Pools	Total	
2	SS-11D	471	1,078	44
	SS-13	669	1,102	61
	SS-14	722	1,054	69
3	SS-15A-2	93	1,022	9
	SS-15B	94	637	15
4	SS-17D	447	1,002	45
	SS-19	674	1,074	63

8.3.2 Width to Depth Ratio

Lateral channel cross sections for each monitoring reach are depicted in Figure 8-12 (Site SS-11D), Figure 8-13 (Site SS-13), Figure 8-14 (Site SS-14), Figure 8-15 (Site SS-15A-2), Figure 8-16 (Site SS-15B), Figure 8-17 (Site SS-17D), and Figure 8-18 (Site SS-19). Mean width to depth ratios among those sites ranged from 17.1 to 21.4 (Table 8-4; Table 8-5; Table 8-6). Within reaches, variation in the width to depth ratios among the cross-sections was quite low with no sites having a standard deviation exceeding 4.9 (Table 8-4; Table 8-5; Table 8-6). All sites had mean width to depth ratios exceeding the reference range (Figure 8-19). The reference range was exceeded in 89 percent of all cross-sections monitored in 2018 (n = 71) and in all cross-sections in Sites SS-15B, SS-17D, and SS-19 (Table 8-4; Table 8-5; Table 8-6).

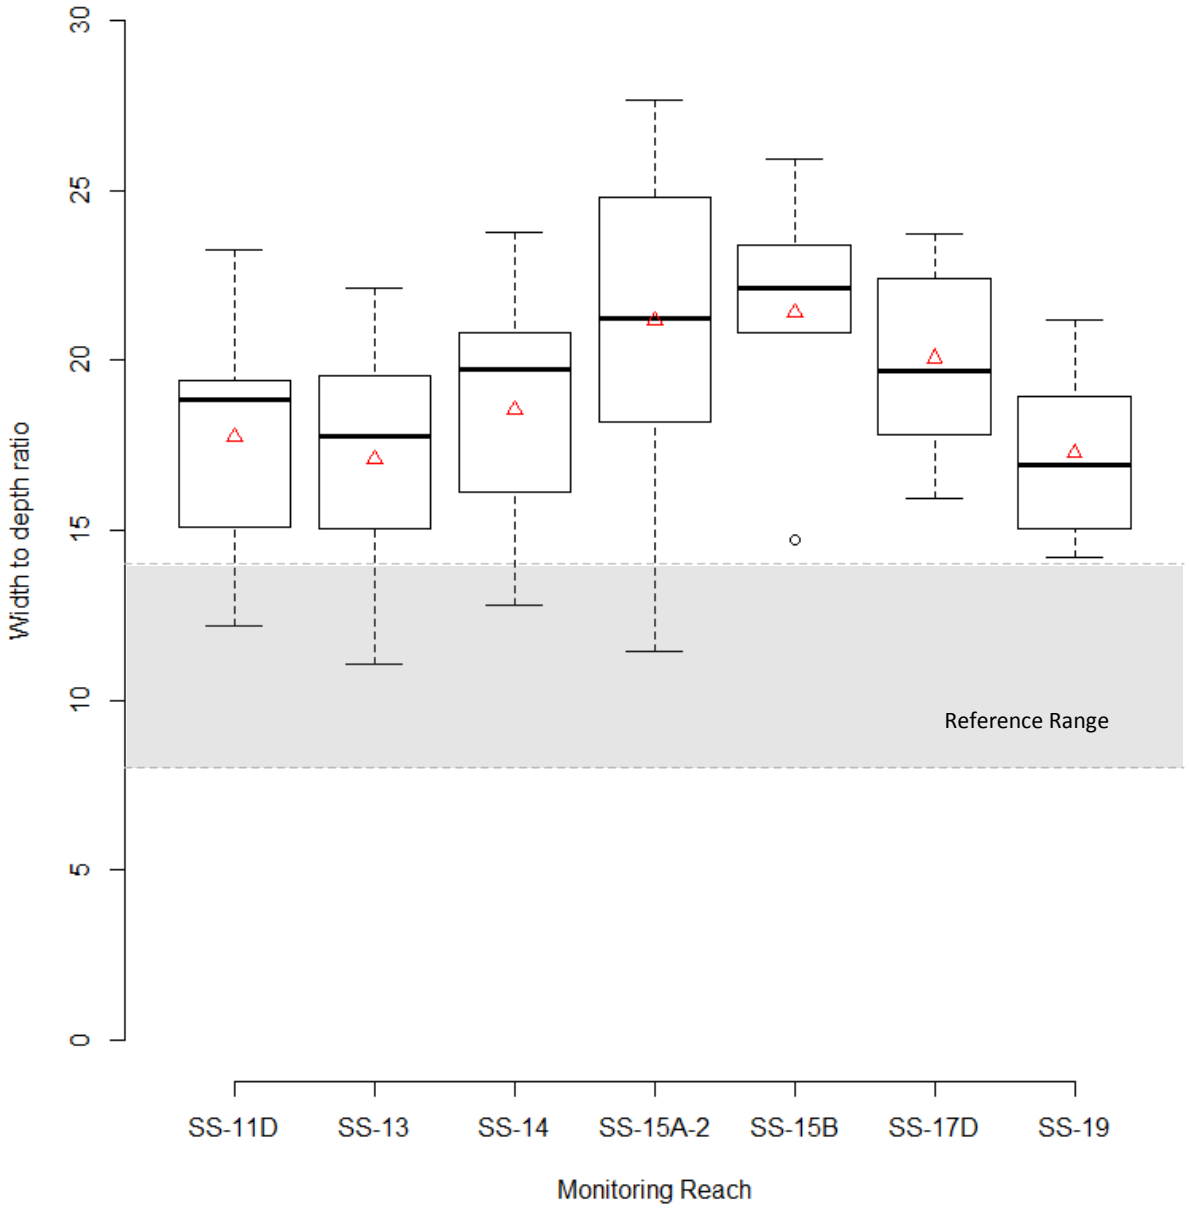

Figure 8-19. Width to depth ratios among cross-sections of monitoring reaches in the Streamside Tailings Operable Unit, 2016. Red triangle represents group mean.

8.3.3 Undercut Banks

Mean undercut streambanks exceeded the reference value range (8-20 percent) at four sites (Sites SS-11D, SS-13, SS-14, and SS-15A-2), was below the reference value range at one site (Site SS-17D), and was within the reference value range in two sites (Sites SS-15B and SS-19) (Table 8-7; Figure 8-20). In the Subarea 2 sites (Sites SS-11D, SS-13, and SS-14), the mean undercut proportion was well above the reference value range at 94 percent, 80 percent, and 66 percent for each site, respectively (Table 8-7). In the Subarea 3 sites, the mean undercut proportion was slightly above the reference value range in Site SS-15A-2 at 33 percent and within the reference range in Site SS-15B at 10 percent (Table 8-7). In the Subarea 4 sites, the mean undercut proportion was below the reference value range in Site SS-17D at 2 percent and within the reference range in Site SS-19 at 20 percent (Table 8-7). Among all sites, the overall mean undercut bank proportion was 44 percent. There was a general decrease in the proportion of undercut banks from the upstream-most to the downstream-most.

Table 8-7. Estimated proportion of undercut banks within monitoring reaches of the Streamside Tailings Operable Unit, 2018.

Monitoring Reach	Survey Locations	Surveyed Length (feet)	Undercut Length (feet)	Mean Proportion Undercut (%)	Standard Deviation
SS-11D	22	660	623	94.4	12.4
SS-13	22	660	530	80.3	24.2
SS-14	22	660	435	65.9	35.0
SS-15A-2	22	660	215	32.6	29.1
SS-15B	22	660	65	9.8	25.0
SS-17D	22	660	15	2.3	5.6
SS-19	22	660	130	19.7	25.3

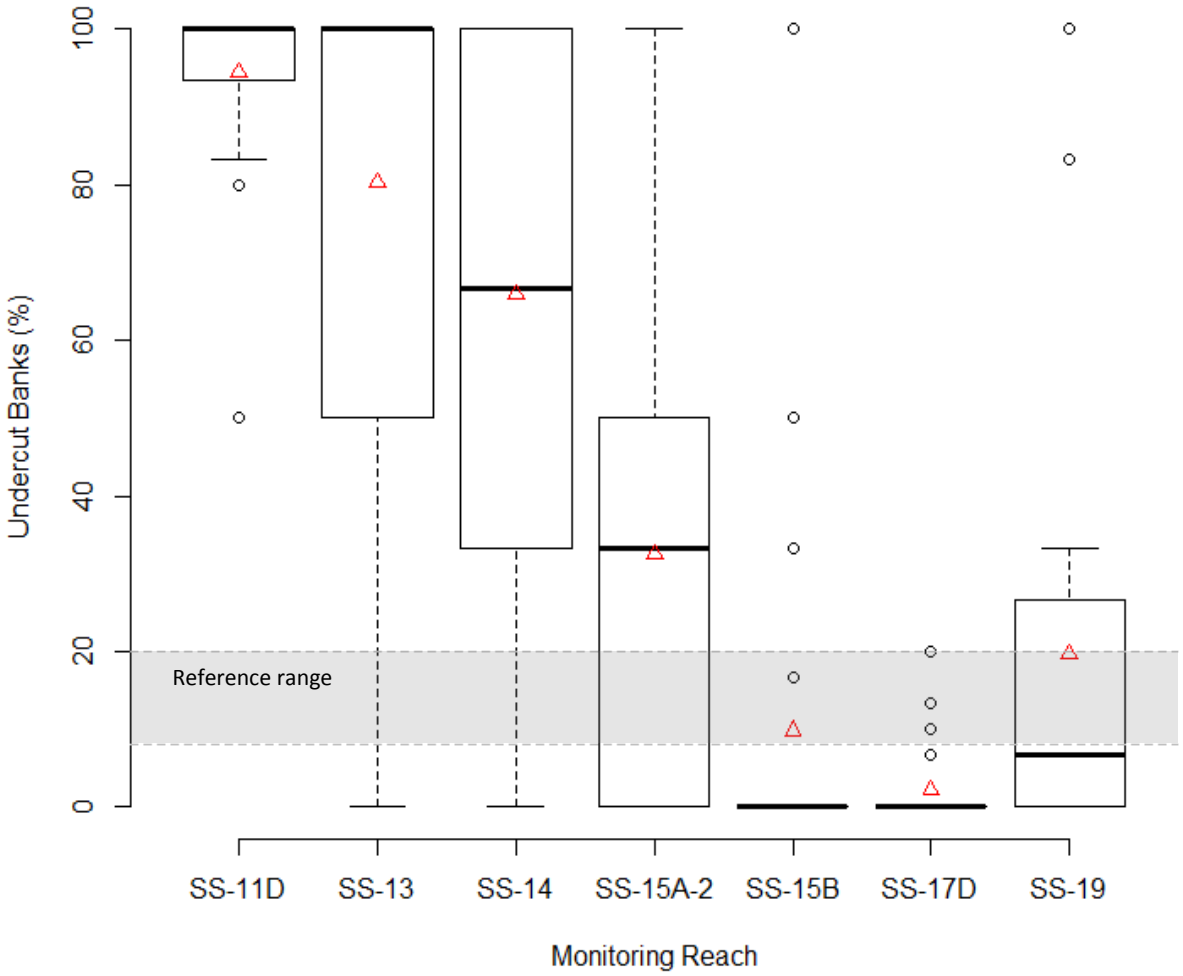

Figure 8-20. Estimates of undercut bank proportions at survey locations (n = 22) within each monitoring reach of the Streamside Tailings Operable Unit, 2018. Red triangles represent group means.

8.3.4 Riparian Cover

Mean overstory cover proportion was low (less than 6 percent) at all sites in 2018 with the exception of Site SS-15B (Table 8-8; Figure 8-21). Site SS-15B had relatively high overstory cover (19 percent), compared to other sites, but overstory cover at Site SS-15B was still well below the reference range for overstory cover (45-65 percent). Mean understory cover proportion was also generally low (0.2-31 percent) at all sites in 2018 (Table 8-8; Figure 8-21). Mean ground cover proportion was generally high (92-99 percent) at all sites in 2018 with the exception of the Subarea 3 sites (Sites SS-15A-2 and SS-15B) (Table 8-8; Figure 8-21). Mean ground cover in the Subarea 3 sites was low (less than 50 percent) (Table 8-8; Figure 8-21). The low groundcover at the Subarea 3 sites was largely due to railroad and roadway grades within the riparian zone where the vegetation cover plots were established.

Table 8-8. Estimated proportion of cover from riparian vegetation within monitoring reaches of the Streamside Tailings Operable Unit, 2018.

Monitoring Reach	Vegetation Cover (%)					
	Ground (<0.5 m)		Understory (0.5-5 m)		Overstory (>5 m)	
	Mean	Standard Deviation	Mean	Standard Deviation	Mean	Standard Deviation
SS-11D	99.1	2.9	23.4	20.7	0.0	0.0
SS-13	98.6	3.5	30.5	18.6	0.0	0.0
SS-14	92.3	13.0	12.3	9.5	0.5	1.5
SS-15A-2	49.5	41.4	0.5	1.5	5.5	17.9
SS-15B	47.7	32.9	20.9	23.4	19.1	21.6
SS-17D	94.1	9.3	7.3	4.8	0.9	3.3
SS-19	93.9	17.6	0.2	0.6	0.0	0.0

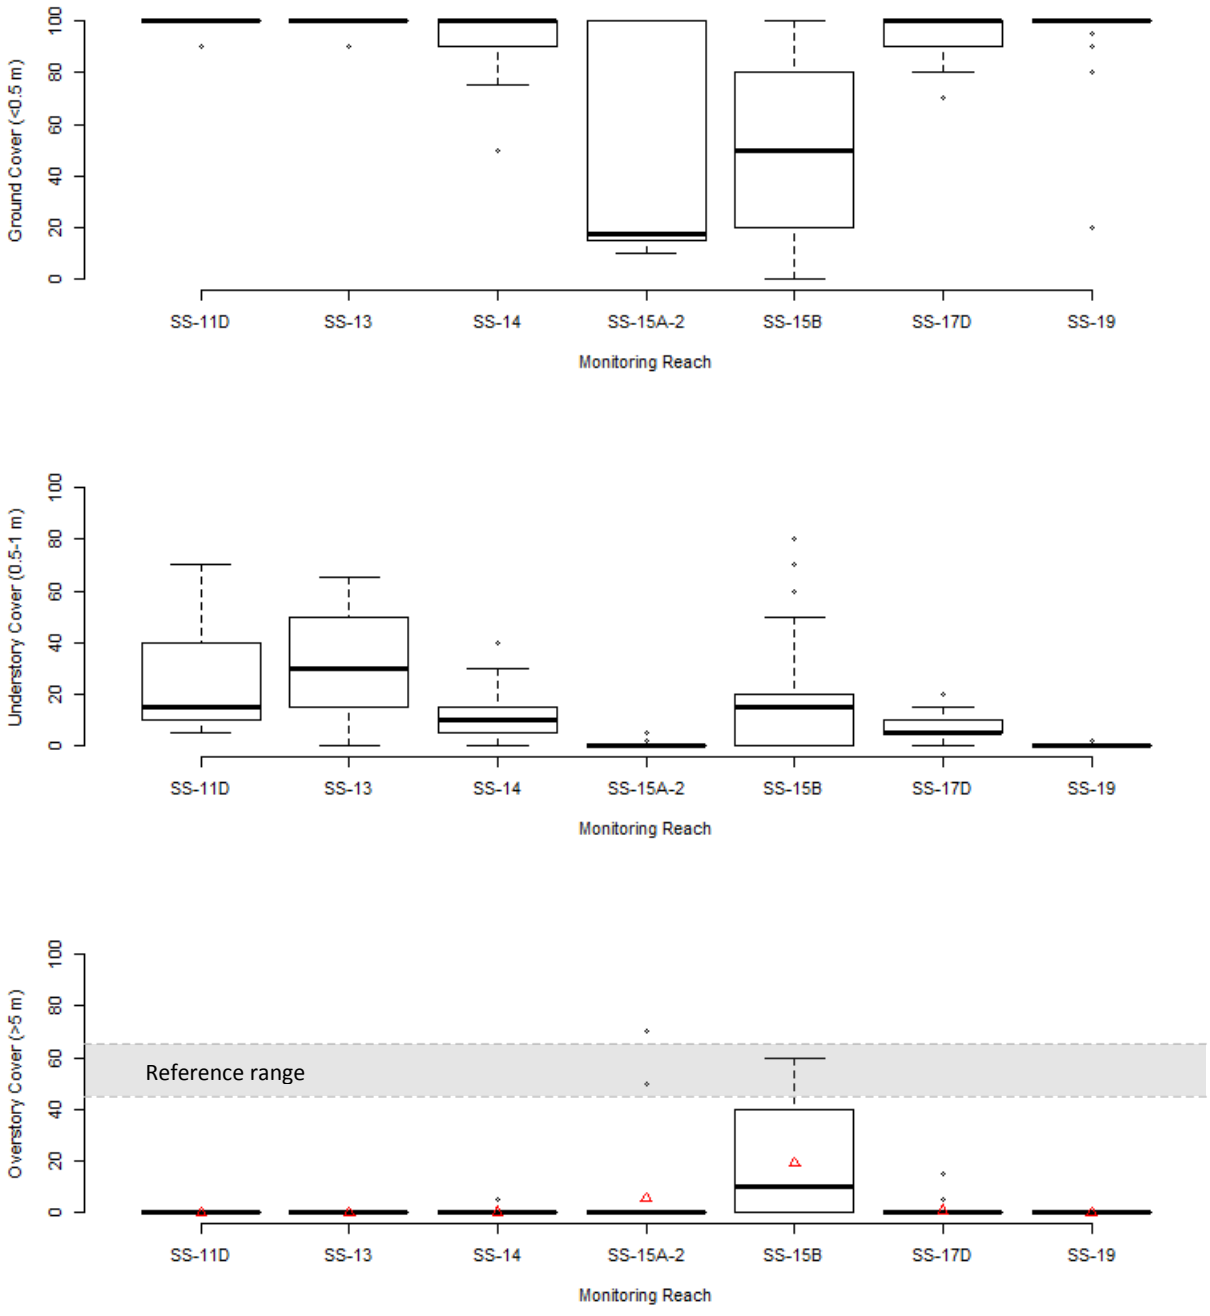

Figure 8-21. Riparian cover in monitoring reaches of the Streamside Tailings Operable Unit, 2018. Red triangle represents group mean.

8.3.5 Channel Cover

Mean channel shading in the monitoring sites in 2018 ranged from 0.1 percent at Site SS-19 to 24.6 percent at Site SS-15B (Table 1-1). Channel shading was within the reference range at all Subarea 2 and Subarea 3 sites (Sites SS-11D, SS-13, SS-14, and SS-15B) with the exception of Site SS-15A-2 (Figure 8-22). Shading in Site SS-15A-2 was below the reference range (Figure 8-22), potentially largely because in that reach, the railroad grade on the south side of the stream was located very close (generally within 5 m) to the stream channel which limited growth of streamside vegetation. Both Subarea 4 sites had low (i.e., less than 5 percent) channel shading (Figure 8-22).

Table 8-9. Stream channel shading in monitoring reaches of the Streamside Tailings Operable Unit, 2018.

Reach	Densiometer dots shaded (%)	
	Cross-section total	
	Mean	Standard Deviation
SS-11D	22.2	12.1
SS-13	20.8	13.9
SS-14	17.2	12.0
SS-15A-2	5.7	5.2
SS-15B	24.6	13.3
SS-17D	4.8	7.5
SS-19	0.1	0.3

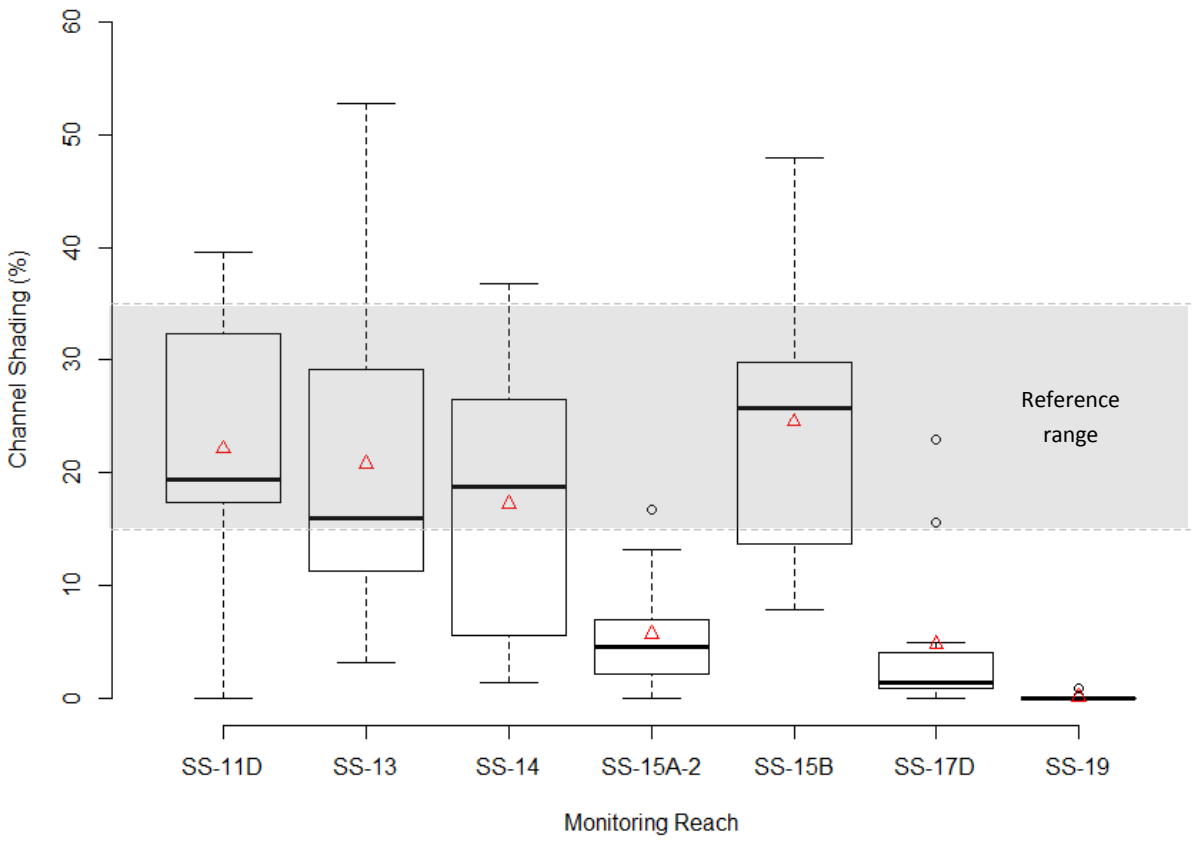

Figure 8-22. Channel shading estimates monitoring reaches of the Streamside Tailings Operable Unit, 2018.

8.3.6 Woody Debris

The mean proportion of streambank cover provided by large wood was 0% at five of the seven sites monitored in 2018 (Table 8-10). Two sites had at least some cover provided by wood: Sites SS-14 and SS-15B (Table 8-10). In those sites, cover provided by wood was low (not more than 3 percent) (Table 8-10). The reference value range for streambank cover from large wood is 15-35%.

Table 8-10. Cover provided by large woody debris along the streambanks in monitoring reaches of the Streamside Tailings Operable Unit, 2018.

Monitoring Reach	Survey Locations	Surveyed Length (feet)	Length Covered by Wood (feet)	Mean Proportion Covered by Wood (%)	Standard Deviation (%)
SS-11D	22	660	0	0	0
SS-13	22	660	0	0	0
SS-14	22	660	10	1.5	7.1
SS-15A-2	22	660	0	0	0
SS-15B	22	660	20	3.0	1.0
SS-17D	22	660	0	0	0
SS-19	22	660	0	0	0

8.4 DISCUSSION

Results of geomorphic monitoring in the SSTOU in 2018 indicate that the reconstructed channel characteristics were within the reference value range for percent pools at two sites (Sites SS-11D and SS-17D), for undercut banks at two sites (Sites SS-15B and SS-19), and at four sites for channel cover (Sites SS-11D, SS-13, SS-14, and SS-15B) (Table 8-11). No sites were within the reference ranges for width to depth ratio, riparian cover, or woody debris (Table 8-11).

Pool availability was within or above the reference range in all Subarea 2 and 4 sites (Sites SS-11D, SS-13, SS-14, SS-17D, and SS-19) monitored in 2018 (Table 8-11). Both Subarea 3 sites were below the reference range. The relative scarcity of pools in the Subarea 3 sites is likely due to channel development constraints due to adjacent railroad grades in Subarea 3.

The width to depth ratio was above the reference range at all sites in 2018 indicating that the channel is relatively wide and shallow (Table 8-11). Shallower stream channels in small streams may increase exposure of fish to predation and also decrease thermal buffering resulting in greater temperature extremes during hot and cold periods [Torgersen et al., 1999]. However, wide, shallow streams are also generally more geomorphically stable because stream power is distributed across a greater surface area and therefore the stream may be less prone to channel incision.

With the exception of one site in Subarea 4 (Site SS-17D), all sites had proportions of undercut banks that were within or above the reference range (Table 8-11).

Riparian overstory cover and woody debris cover were below the reference range at all sites in 2018 (Table 8-11). Low riparian overstory cover reflects the general scarcity of large tree plantings in the riparian area of the SSTOU. Similarly, given the lack of large woody debris incorporated into the remedial design, woody debris was essentially absent at all sites. Over the long-term, large trees may (or may not) become more common on the floodplain through natural recruitment and those trees eventually would then be incorporated into the channel as large woody debris. However, ten years is clearly not a sufficient time period to evaluate natural recruitment of large woody tree species and recruitment of debris from those trees. Despite the low overstory cover, which is generally considered a condition beneficial for trout in streams [Romero et al., 2005], trout including westslope cutthroat trout have thrived in remediated portions of Silver Bow Creek [Naughton, 2013; RESPEC, 2015]. During extensive sampling of fish, habitat and water quality in Silver Bow Creek between 2010 and 2011, overhead riparian cover had little or no association with trout abundance in Silver Bow Creek [Naughton, 2013] perhaps because other important cover features (e.g., the relative availability of deep pools and undercut streambanks) compensate for the scarcity of cover.

Channel cover was within the reference range at all Year-10 monitoring sites and at one Year-5 monitoring site in 2018 (Table 8-11). Growth of streamside willows and shrubs appears to be directly related to the time that has elapsed since revegetation was complete at each site. In the Subarea 2 sites, willows and shrubs have grown vigorously and now provide extensive channel cover despite the lack of overstory cover. The Subarea 4 sites, revegetated well after the Subarea 2 sites, had relatively low channel cover in 2018. Channel cover was low in the Subarea 2 Site SS-15A-2 due to the railroad grades adjacent to the stream channel and the lack of suitable floodplain area for riparian growth. Generally, at all sites willow and shrub growth was most vigorous at the stream margins and appeared to decrease with lateral distance from the streambanks.

The Subarea 2 sites (Sites SS-11D, SS-13, and SS-14) deserve particular attention in this report because each has surpassed the ten-year post remediation period and all have now been monitored during the Year-5 and Year-10 monitoring periods. As of Year-10 (2018), pools, undercut banks and streamside cover were either within or above the reference ranges at these sites; riparian overstory cover and woody debris were essentially absent and below the reference ranges at all sites; and the channel was wide and shallow compared to reference conditions at all sites (Table 8-11). Most metrics had similar results in Year-5 and Year-10 with the exceptions of pool and undercut bank prevalence which increased substantially at all sites (Table 8-11). Streamside cover [Romero et al., 2002], pools [McIntyre and Riemann, 1995], and undercut banks [Butler and Vernon, 1968; Myers and Resh, 2000] are important habitat features for trout and other aquatic organisms.

Table 8-11. Summary of geomorphology monitoring results by reach in the Streamside Tailings Operable Unit, 2018.

Site	Monitoring Year		Monitoring Metric					
	Scheduled	Actual	Percent pools (%)	Width to depth ratio	Undercut banks (%)	Riparian cover; overstory (>5 m) canopy (%)	Channel cover (%)	Woody debris (%)

9.0 CONCLUSIONS

This chapter concludes the 2018 monitoring report and provides an evaluation of monitored conditions in relation to performance standards specified in the SSTOU ROD [DEQ and USEPA, 1995]. Numeric performance standards are specified in the ROD for surface water and groundwater COC concentrations [DEQ and USEPA, 1995], and therefore this chapter focuses on those media. While more stringent standards promulgated since the issuance of the ROD have not yet been formally adopted as performance standards for this operable unit, this monitoring report uses the more stringent of the ROD's Circular WQB-7 [MDHES, 1994] standards or current Circular DEQ-7 [DEQ, 2017] standards as the goal to be attained for purposes of evaluation.

For surface water and groundwater, sample concentrations from this monitoring year are compared to performance goals at each SSTOU surface water monitoring site (Sites SS-07, SS-08, SS-10A, SS-11C, SS-11D, SS-13, SS-14, SS-15A-2, SS-15B, SS-16B, SS-17D, and SS-19; Figure 1-2), groundwater monitoring well in the vicinity of the Mine Waste Relocation Repository (Wells 1GW-1056, LYP-07, MW-2B, MW-2C, and MW-2D; Figure 3-1) and groundwater monitoring floodplain well clusters (Clusters Colorado Tailings, Rocker, Nissler, Silver Bow, Miles Crossing, Fairmont, Crackerville, Stuart, and Frontage Road; Figure 3-1). Results for surface water sites located outside the SSTOU (Sites SS-01, SS-05A, SS-06G, and SS-15G; Figure 1-2) and background groundwater wells (Figure 3-1) are not summarized in this chapter. A summary of performance goal exceedances is provided in Table 9-1 (surface water), Table 9-2 (groundwater in the vicinity of the Mine Waste Relocation Repository), and Table 9-3 (groundwater in the SSTOU floodplain). In addition, this chapter provides a brief comparison of COC concentrations between surface water sites and in groundwater clusters to identify potential remaining COC source areas within the SSTOU.

Major remedial work in the Streamside Tailings Operable Unit was completed by the end of 2015. Cleanup consisted of excavation of tailings (mine waste containing heavy metals) and related impacted soils from the floodplain of Silver Bow Creek, reconstruction of the stream channel and floodplain, and revegetation. Recent additional repair work in Subareas 1 and 2 occurred from 2016 to 2018 to address small deposits of remaining remnant tailings-impacted soils. These data will guide managers in identifying progress or problems in the recovery of the operable unit following implementation of the remedial actions.

Table 9-1. Attainment of surface water performance goals for contaminants of concern at sampling sites in the Streamside Tailings Operable Unit (SSTOU), 2018. Sites within the watershed but outside the SSTOU are not included.

Subarea	Site ID	Site Location	Contaminant of Concern[63]					
			As	Cd	Cu	Pb	Hg	Zn
1	SS-07	Silver Bow Creek below Butte WWTP						
	SS-08	Silver Bow Creek at Rocker						
	SS-10A	Silver Bow Creek above Sand Creek						
2	SS-11C	Silver Bow Creek above Browns Gulch						
	SS-11D	Silver Bow Creek below Browns Gulch

Failure to attain the performance goal in both monitoring well samples.

9.1 SUBAREA 1

Major remediation in Subarea 1 was completed between 1999-2003, however some additional remedial actions were in progress in Subarea 1 and 2 recently to address some of the remaining COC sources in the floodplain.

Surface water sites in Subarea 1 include Sites SS-07, SS-08, and SS-10A (Figure 1-2). In 2018, COC concentrations were similar to those measured in 2017, although this approached the higher end of the range of concentrations from prior monitoring periods. In general, surface water total recoverable arsenic and copper concentrations showed a slight increase, particularly in Q1 and Q2 and below the recent repair work. Lead and zinc concentrations generally decreased from 2017 concentrations, throughout Subarea 1, with the exception of the Q4 event.

Groundwater monitoring clusters in Subarea 1 include the Colorado Tailings, Rocker, and Nissler clusters (Figure 3-1). In certain Subarea 1 groundwater monitoring wells, zinc concentrations have consistently exceeded the performance goal (by as much as five times). Arsenic and cadmium concentrations have also occasionally exceeded the performance goals in Subarea 1 monitoring wells. Copper concentrations have not exceeded the performance goal during the period of record in these wells but have regularly been elevated in monitoring wells compared to the background wells.

9.1.1 Surface Water

9.1.1.1 Silver Bow Creek below Butte WWTP (SS-07)

Site SS-07 is located at the upstream end of Subarea 1, immediately downstream from the Butte WWTP outfall. Site SS-07 is the upstream-most site in the SSTOU. Remediation was completed at Site SS-07 in 2000. In addition to representing conditions at the upstream-most portion of the SSTOU, Site SS-07 provides an assessment of the influence of the WWTP on water chemistry and biological integrity in Silver Bow Creek. Site SS-07 is paired with Site SS-06G, located immediately upstream from the WWTP, with Site SS-06G providing the "control" site and Site SS-07 providing the "impact" site for the WWTP outfall. Site SS-07 is co-located with USGS gage 12323250.

In 2018, arsenic and copper exceeded the performance goals at Site SS-07 in Q2. During most quarters in 2018, most COC concentrations at Site SS-07 were similar to (and, generally slightly less than) concentrations at Site SS-06G. However, zinc was an exception. During all quarters zinc concentrations at Site SS-07 were higher than at Site SS-06G. These results suggest that the discharge of the Butte WWTP in 2018 tended to dilute concentrations in Silver Bow Creek for each metal COC except zinc

9.1.1.2 Silver Bow Creek at Rocker (SS-08)

Site SS-08 is in Subarea 1 near the town of Rocker, approximately two miles downstream from Site SS-07. Site SS-08 was remediated in 2002. No tributaries enter Silver Bow Creek between Sites SS-07 and SS-08. Therefore, any differences in streamflow (not due to measurement error) between Sites SS-07 and SS-08 would likely be attributed to exchange between groundwater and surface water in this reach.

In 2018, arsenic, copper, and mercury exceeded the performance goals at Site SS-08 during at least one quarter. Exceedances of the performance goals occurred for arsenic in Q2, copper in Q1, Q2, and Q4, and mercury in Q2, Q3, and Q4. Concentrations of all COCs increased between Sites SS-07 and SS-08, and this was observed in each quarter of 2018. These results suggest that loading or mobilization of those contaminants occurs between those sites. Monitoring in 2019 and beyond will elucidate the effectiveness of recent remedial actions between these sites (which occurred in 2016) at reducing COC loading.

9.1.1.3 Silver Bow Creek above Sand Creek (SS-10A)

Site SS-10A is located at the downstream end of Subarea 1, immediately upstream from the Sand Creek confluence, approximately 3 miles downstream from Site SS-08. Remediation at Site SS-10A was completed in 2003. Site SS-10A represents conditions at the downstream end of Subarea 1.

In 2018, performance goals were exceeded at Site SS-10A for arsenic in Q1, for copper in all quarters, and for mercury in Q2, Q3, and Q4. Between Sites SS-08 and SS-10A an increase was observed in cadmium, copper, and zinc in all monitoring events.

9.1.2 Groundwater

9.1.2.1 Colorado Tailings Cluster

The Colorado Tailings cluster is located approximately one mile downstream from the upstream end of Subarea 1 between surface water Sites SS-07 and SS-08. There are no surface water inputs in this reach (between Sites SS-07 and SS-08) and streamflows are similar [RESPEC, 2018a] suggesting that groundwater in this reach does contribute appreciably to surface water streamflow.

In 2018, no COCs exceeded performance goals in groundwater samples from the Colorado Tailings cluster. Zinc concentration in one monitoring well was elevated compared to the background well

9.1.2.2 Rocker Cluster

The Rocker cluster is located approximately 0.5 miles downstream from surface water Site SS-08, and approximately 2 miles upstream from surface water Site SS-10A. There are no surface water inputs in this reach (between Sites SS-08 and SS-10A) and streamflows are similar [RESPEC, 2018a] suggesting that groundwater in this reach does contribute appreciably to surface water streamflow.

In 2018, one of the two monitoring wells in the Rocker cluster exceeded the performance goals for arsenic and zinc. Cadmium, copper and zinc concentrations were elevated in both monitoring wells compared to the background well.

9.1.2.3 Nissler Cluster

The Nissler cluster is located approximately 1.5 miles downstream from the Rocker cluster and is also located between surface water Sites SS-08 and SS-10A. Despite historically elevated COC concentrations in this portion of the floodplain of Silver Bow Creek between Sites SS-08 and SS-10A, groundwater may not be the primary cause of increasing surface water COC concentrations between these sites given that it appears little groundwater enters Silver Bow Creek in this portion of Subarea 1.

In 2018, cadmium (in one monitoring well), lead (in one monitoring well), and zinc (in both monitoring wells) exceeded performance goals in the Nissler cluster. Cadmium, copper, and zinc concentrations in both monitoring wells were elevated relative to the background concentrations

and lead concentration was elevated in one monitoring well. It should be noted that elevated arsenic concentrations have consistently been observed in the Nissler cluster background well, where the MDHES human health standard was exceed in 2018.

9.2 SUBAREA 2

Subarea 2 includes Sites SS-11C, SS-11D, SS-13, and SS-14.. Remediation in Subarea 1 was completed between 2004-2010. In 2018, surface water COC concentrations tended to remain relatively consistent among Subarea 2 sites, although with variation. Perforance goals were exceeded for arsenic at all of the Subarea 2 surface water sites in Q1 and Q2; copper in all quarters for 2 sites and all quarters except Q3 for the other 2 sites; mercury at all sites in Q1 snd 2 sites in both Q2 and Q3. Some additional remedial actions occurred in Subarea 2 from 2016 through 2018 to address some remaining COC sources in the floodplain.

Groundwater monitoring clusters in Subarea 2 include the Silver Bow and Miles Crossing clusters (Figure 3-1). Arsenic concentrations exceeded performance standards in one of the monitoring wells, as well as one of the background wells in 2018. Cadmium concentrations exceeded the performance goal in 3 of 4 monitoring wells and zinc exceeded the goal in 2 of 4 wells in the Subarea 2 floodplain. Concentrations in one or more monitoring wells were considerably higher than in the paired background wells for cadmium and zinc concentrations.

9.2.1 Surface Water

9.2.1.1 Silver Bow Creek above Browns Gulch (SS-11C)

Site SS-11C is in Subarea 2, immediately upstream from the Browns Gulch confluence, approximately 2.5 miles downstream from Site SS-10A. Site SS-11C was remediated in 2006. Site SS-11C provides an assessment of the influence of Browns Gulch on water chemistry and biological integrity in Silver Bow Creek. Site SS-11C is paired with Site SS-11D, which is located immediately downstream from the Browns Gulch confluence. Site SS-11C provides the "control" site, and Site SS-11D provides the "impact" site for the Browns Gulch input.

Between Sites SS-10A and SS-11C, some COC concentrations increased during some quarters but during other quarters concentrations were similar or lower at Site SS-11C. The only COC that exhibited consistent behavior, where concentrations decreased between Sites SS-10A and SS-11C for all quarters. No other water quality parameter showed a consistent increase of decrease between sites throughout 2018, however some general tendencies were observed. Arsenic and zinc tended to increase between Sites SS-10A and SS-11C (3 out of 4 quarters); whereas, cadmium, copper, and mercury tended to decrease (3 out of 4 quarters).

9.2.1.2 Silver Bow Creek below Browns Gulch (SS-11D)

Site SS-11D is in Subarea 2, immediately downstream from the Browns Gulch confluence, approximately 200 m downstream from Site SS-11C. Site SS-11D was remediated in 2007. Site SS-11D provides an assessment of the influence of Browns Gulch on water chemistry and biological integrity in Silver Bow Creek. Site SS-11D is paired with site SS-11C (which is located immediately upstream from the Browns Gulch confluence), with SS-11C providing the "control" site and SS-11D providing the "impact" site for the Browns Gulch input.

Again, a consistent behavior between these two sites was not observed amongst all COCs during 2018. However, an increase in cadmium and zinc concentrations between sites SS-11C and SS-11D for all quarters and in mercury in 3 out of 4 quarters. In general, copper (3 out of 4 quarters) and zinc concentrations (all quarters) were lower at SS-11D than SS-11C in 2018. This suggests that Browns Gulch flows may contribute of mobilize some COCs while reducing mainstem concentrations of other COCs slightly through dilution.

9.2.1.3 Silver Bow Creek in Reach L (SS-13)

Site SS-13 is in Subarea 2, downstream from the Browns Gulch confluence, approximately 0.75 miles downstream from Site SS-11D. Site SS-13 was remediated in 2007, but this site was not sampled until 2013.

Generally, COC concentrations were similar in Sites SS-11D and SS-13, although some COCs showed increasing or decreasing tendencies between these sites. Cadmium and lead concentrations were both consistently slightly lower at Site SS-13 compared to Site SS-11D (all quarters) and mercury concentrations were lower at Site SS-13 in 3 out of 4 quarters. Slightly higher downstream concentration of copper and zinc were observed at Site SS-13 in 3 out of 4 quarters (all except Q4).

9.2.1.4 Silver Bow Creek at Miles Crossing (SS-14)

Site SS-14 is located near the downstream end of Subarea 2. Remediation was completed at Site SS-14 in 2008. Site SS-14 is in the Miles Crossing area approximately 1 mile downstream from Site SS-13.

Generally, COC concentrations were similar between Sites SS-13 and SS-14 during all quarters although lead showed a slight decrease in COC concentrations at Site SS-14 for all quarters and cadmium and mercury concentrations were lower at Site SS-14 in all quarters except Q1. Zinc and copper concentrations were both increased from Site SS-13 to Site SS-14 in Q1 and Q2, then decreased between these two sites on Q3 and Q4.

9.2.2 Groundwater

9.2.3 Silver Bow Cluster

The Silver Bow cluster is located at the boundary between Subarea 1 and Subarea 2, close to the surface water Site SS-10A. Surface water Site SS-10A is located approximately 3 miles upstream from Site SS-11C. Between Sites SS-10A and SS-11C, streamflow increases by 10 percent (2.9 ft^3/s) on average [RESPEC, 2018a]. There are multiple ponds adjacent to Silver Bow Creek in this reach with surface water discharge into Silver Bow Creek. These inputs, in addition to other potential groundwater sources, account for the net increase in streamflow between these sites

In 2018, the performance goals were exceeded in one of two monitoring wells for arsenic and cadmium in the Silver Bow cluster.

9.2.3.1 Miles Crossing Cluster

The Miles Crossing cluster is located at the boundary between Subarea 2 and Subarea 3, close to the surface water Site SS-14. Surface water Site SS-15A is located approximately 5 miles downstream from Site SS-14. There are no surface water inputs in this reach (between Sites SS-14 and SS-15A) and streamflows are similar [RESPEC, 2018a] suggesting that groundwater in this reach does contribute appreciably to surface water streamflow.

In 2018, cadmium and zinc exceeded the performance goal in both monitoring wells located in the Miles Crossing cluster and concentrations were several orders of magnitude above the concentrations in the background well. The background well in the Miles Crossing Cluster exceeded the arsenic groundwater standard in 2018.

9.3 SUBAREA 3

Subarea 3 includes Sites SS-15A and SS-15B. Remediation in Subarea 3 occurred from 2011 to 2015. Prior to 2014 monitoring, surface water COC concentrations tended to be the highest in the SSTOU at these Subarea 3 sites (particularly Site SS-15A). However, COC concentrations at these sites have generally been similar to concentrations in Subarea 2 since 2014. These results indicate that the recent remedial actions in Subarea 3 upstream from these sites were largely successful at reducing surface water COC concentrations and variability.

9.3.1 Surface Water

9.3.1.1 Silver Bow Creek above German Gulch (SS-15A-2)

Site SS-15A is in Subarea 3, immediately upstream from the German Gulch confluence and approximately 3.5 miles downstream from Site SS-14. Remediation was completed in Subarea 3 upstream from Site SS-15A in 2014. However, the stream channel and floodplain in the immediate vicinity of Site SS-15A (up to 100 m upstream) was not actively remediated. The remediation plan in this vicinity is for natural attenuation of streamside tailings. No active remediation occurred because the stream passes through a very narrow canyon (approximately 30 m) and the streambed is comprised primarily of bedrock indicating that the volume of tailings is relatively small.

Site SS-15A, and the nearby Site SS-15A-2 (located immediately above the zone of natural attenuation treatment), provides an assessment of the influence of German Gulch on water chemistry and biological integrity in Silver Bow Creek. Site SS-15A-2, sampled since 2017, is paired with Site SS-15B which is located immediately downstream from the German Gulch confluence. Site SS-15A-2 provides the "control" site and Site SS-15B provides the "impact" site for the German Gulch input. The COC concentrations were similar at Site SS-14 and Site SS-15A-2 during some quarters, but during other quarters concentrations were highly variable between the sites in 2018.

9.3.1.2 Silver Bow Creek below German Gulch (SS-15B)

Site SS-15B is in Subarea 3, immediately downstream from the German Gulch confluence and approximately 200 m downstream from Site SS-15A. Site SS-15B was located at the downstream edge of the non-remediated portion of Subarea 3. Downstream from Site SS-15B, remediation was completed in 2015 but upstream for approximately 300 m the stream channel and floodplain were not remediated due to low tailings volume in this reach and poor access. The remediation plan for this short reach (about 300 m from Site SS-15B to 100 m upstream from Site SS-15A) is for natural attenuation.

Site SS-15B provides an assessment of the influence of German Gulch on water chemistry and biological integrity in Silver Bow Creek. Site SS-15B is paired with Site SS-15A which is located immediately upstream from the German Gulch confluence. Site SS-15A provides the "control" site and Site SS-15B provides the "impact" site for the German Gulch input. Concentrations of all COCs observed at Site SS-15B were consistently lower than those observed at Site SS-15A in 2018 during all quarters. These results are consistent with past results and presumably reflect dilution from the relatively clean German Gulch tributary.

9.3.2 Groundwater

There were no groundwater monitoring wells located in Subarea 3 in 2018. The Miles Crossing cluster is in Subarea 2 near the boundary with Subarea 3 and the Fairmont cluster is in Subarea 4 near the boundary with Subarea 3.

9.4 SUBAREA 4

Subarea 4 includes Sites SS-16B, SS-17D, and SS-19. Remediation in this subarea occurred from 2004-2014. Generally, COC concentrations have continued a steady, modest decline at the Subarea 4 sites during the last 6 years. Remediation was in progress in Subarea 3 upstream from Subarea 4 through 2015. A temporary sedimentation pond, used to sequester metals and sediments entrained from removal activities upstream, was removed in 2014. That pond had previously provided a buffer to water quality in Subarea 4.

Groundwater monitoring clusters in Subarea 4 include the Fairmont, Crackerville, Stuart, and Frontage Road clusters (Figure 3-1). Arsenic and copper concentrations exceeded performance standards in one of the monitoring wells, and arsenic exceeded the MDPES human health standard in one of the background wells as well in 2018. Cadmium concentrations exceeded the performance goal in 3 of the monitoring wells and zinc exceeded the goal in 2 of the wells in the Subarea 4 floodplain.

9.4.1 Surface Water

9.4.1.1 Silver Bow Creek in Reach P near Fairmont (SS-16B)

Site SS-16B is located at the upstream end of Subarea 4. As of 2013, remediation was completed at Site SS-16B. Site SS-16B is located approximately 2 miles downstream from Site SS-15B. A sedimentation pond was removed, and a fish movement barrier was installed, between Sites SS-15B and SS-16B in 2014. Site SS-16B was first sampled in this monitoring program in 2013.

Generally, COC concentrations at Site SS-16B were similar to Site SS-15B in 2018 for arsenic, cadmium, and copper. Lead, mercury, and zinc concentrations were slightly higher at Site SS-16B than at Site SS-15B for all quarters in 2018.

9.4.1.2 Silver Bow Creek below Stewart Street at Opportunity (SS-17D)

Site SS-17D is in Subarea 4, approximately 6.9 miles downstream from Site SS-16B and approximately 1.5 miles upstream from the point where Silver Bow Creek discharges into the Warm Springs Pond system. Site SS-17D is co-located with USGS gage 12323600. Floodplain remediation was complete at Site SS-17D in 2013.

Generally, COC concentrations increased between Site SS-16B and Site SS-17D in 2018. Concentrations for all COCs except for arsenic were slightly higher at Site SS-17D during all quarters, Arsenic concentrations at Site SS-17B were slightly higher than Site SS-16B during Q1 and Q2 and the same during Q3 and Q4.

9.4.1.3 Silver Bow Creek at Frontage Road (SS-19)

Site SS-19 is in Subarea 4, approximately 1.2 miles downstream from Site SS-17D, and 0.2 miles upstream from the point where Silver Bow Creek discharges into the Warm Springs Pond system. Site SS-19 is the downstream-most site in the SSTOU monitoring network and provides an assessment of water quality in Silver Bow Creek at the downstream end of Subarea 4. Sampling at Site SS-19 was initiated in 2014.

Generally, COC concentrations were similar between Site SS-17D and Site SS-19 in 2018. Mercury concentrations increased slightly between these two sites during all quarters, but no other COC concentrations showed a consistent increase of decrease between sites throughout 2018.

9.4.2 Groundwater

9.4.2.1 Fairmont Cluster

The Fairmont cluster is located at the upstream end of Subarea 4, between surface water Sites SS-15B and SS-16B. Surface water Site SS-15B is located approximately 2 miles upstream from Site SS-16B. Sampling at Site SS-16B began in 2013. There are no surface water inputs in this reach (between Sites SS-05B and SS-16B) and streamflows are similar [RESPEC, 2018a] suggesting that groundwater in this reach does contribute appreciably to surface water streamflow.

In 2018, all COC concentrations in Fairmont cluster monitoring wells were below the performance goals.

9.4.2.2 Crackerville Cluster

The Crackerville cluster is located between surface water Sites SS-16B and SS-17D, approximately 0.5 miles downstream from Site SS-16B. There are no surface water inputs in this reach (between Sites SS-16B and SS-17D) and streamflows are similar [RESPEC, 2018a] suggesting that groundwater in this reach does contribute appreciably to surface water streamflow.

In 2018, one monitoring well in the Crackerville cluster had both arsenic and cadmium concentrations which exceeded the performance goal.

9.4.2.3 Stuart Cluster

The Stuart cluster is located between surface water Sites SS-16B and SS-17D, approximately 1 mile upstream from Site SS-17D. There is no evidence that streamflows differ between those sites [RESPEC, 2018a].

In 2018, both monitoring wells had cadmium and zinc concentrations which exceeded the performance goal and one of the monitoring wells (GW-ST-WS) also had a copper concentration which exceeded the performance goal.

9.4.2.4 Frontage Road Cluster

The Frontage Road cluster is located between surface water Sites SS-17D and SS-19 (very close to Site SS-19), at the downstream end of Subarea 4. Sampling began at Site SS-19 in 2014. There are no surface water inputs in this reach (between Sites SS-17D and SS-19) and streamflows are similar [RESPEC, 2018a] suggesting that groundwater in this reach does contribute appreciably to surface water streamflow.

In 2018, no monitoring wells located in the Frontage Road cluster had a COC concentration exceeding the performance goal.

APPENDIX A

Quality Assurance and Quality Control Review and Summary: Surface Water, Instream Sediment, Groundwater, and Vadose Zone Water

A.1 INTRODUCTION

Specific quality assurance and quality control (QA/QC) requirements for field measurements, sample collection, laboratory analysis, and the reporting of resulting data were established by protocols contained in the quality assurance project plan (QAPP), a component of the approved sampling and analysis plan (SAP) for the Silver Bow Creek Streamside Tailings Operable Unit (SSTOU). The following quality control checklist is a component of the Montana Department of Environmental Quality QA/QC protocols and is an initial step in the review and validation of water chemistry and related data generated under the SSTOU environmental monitoring program. This checklist provides an outline for reviewing and assessing numerous factors potentially affecting data quality and assists in identifying data that may be invalid or require additional documentation.

A.2 QUALITY CONTROL

Work order receipt checklists were completed by Energy Labs for each batch of quarterly samples delivered. These checklists are provided in Appendix B. Specific quality control issues identified included the following:

- First Quarter (Q1): Minor discrepancies between chain of custody labels and sample bottle labels. Sediment samples were not delivered on ice and were received by the laboratory at 6-10 C.
- Second Quarter (Q2): Sediment samples were not delivered on ice and were received by the laboratory at 18-20 C.
- Third Quarter (Q3): Sediment samples were not delivered on ice and were received by the laboratory at 7-8 C.
- Fourth Quarter (Q4): Sediment samples were not delivered on ice and were received by the laboratory at 14-15 C.

A.3 SUMMARY OF QUALITY CONTROL AND ANALYSIS RESULTS

Summarized in this appendix are quality control measures performed on field and laboratory data generated from surface water, instream sediment, groundwater, and vadose zone water samples collected from the SSTOU monitoring events in 2018. Assessed under the DEQ standard quality assurance and quality control protocols are data quality objectives (DQOs), including categories for: “representativeness”, “comparability”, and “completeness”. Also assessed under the DEQ standard quality assurance and quality control protocols are data quality indicators (DQIs) including categories for: ”sensitivity”, “lab precision”, “overall precision”, and “bias and accuracy”.

Overall, DQOs and DQIs were generally met at all monitoring sites in the SSTOU during 2018. Surface water samples were collected and analyzed for total suspended sediment, nutrients, metals (dissolved and total recoverable), and common ions at sample sites on four occasions (quarterly) in 2018. Instream sediment samples were collected and analyzed for metals (total) at the sites during each quarter of 2018 and two additional sites. Groundwater and vadose zone water samples were collected from monitoring wells and lysimeters during Q2 and Q3 and these samples were analyzed for dissolved metals and common ion concentrations.

A.3.1 Representativeness

All surface water, instream sediment, vadose zone water, and groundwater monitoring sites in the SSTOU sampled in 2018 met stated objectives for "spatial representativeness". That is, all monitoring sites were sampled at the established locations specified in the project SAP.

All surface water and instream sediment monitoring was conducted quarterly during 2018 as specified in the project SAP. Q1 monitoring occurred during base streamflow conditions prior to the onset of spring runoff. Q2 monitoring was conducted near the peak annual streamflow the during spring snowmelt runoff period. Biological monitoring was conducted in conjunction with Q3 surface water and instream sediment sampling, during low streamflows near the seasonal minimum within the specified index period for sampling the biota. Q4 monitoring occurred during base streamflow conditions as late in the season as possible, prior to winter ice up. Sampling activities during 2018 occurred during the last month of each respective quarter, and all data met specified SSTOU criteria for temporal representativeness.

A.3.2 Comparability

Comparability is the applicability of project data to the remedial performance goals specified in the SAP for the various environmental media monitored under the project. The performance goal for surface water quality is for all contaminants of concern (COC) to meet the most restrictive of the state water quality standards for surface water. For instream sediment, the goal is for COC concentrations to meet the "threshold effect concentration" (TEC). Performance goals for groundwater call for COC concentrations to meet state water quality standards, federal maximum contaminant levels (MCLs), and federal non-zero MCL goals through natural attenuation. All of these standards and levels apply to human health considerations. In addition, these goals require that no groundwater discharges occur that would prevent attainment of ambient Circular DEQ-7 surface water standards or instream sediment remediation goals in the SSTOU. All data acquired by the 2018 monitoring are applicable to assessing attainment of project performance goals.

A.3.3 Completeness

An overall data completeness goal of 85 percent was specified for the SSTOU project and an evaluation table for data completeness is not required if the goal is met or exceeded. Data completeness for surface water and instream sediment samples from the SSTOU monitoring sites

was near 100 percent, with all chemical and physical parameters collected and analyzed during each of the four quarterly monitoring events. Water samples were collected and analyzed from all SAP-specified groundwater monitoring wells and vadose zone lysimeters during the Q2 and Q3, although the available volume of water was often limited for vadose zone water samples.

A.3.4 Sensitivity

The method detection limit (MDL) established by Energy Laboratories through laboratory blank analyses is an expression of sensitivity. The MDL documented in QA/QC summary reports that accompany each set of laboratory analytical reports was less than the project-required reporting limit (RL), and was often below detection, for all analytical methods pertaining to Silver Bow Creek SSTOU monitoring (Appendix B).

Sensitivity of field methods for surface water samples was determined through deionized water field blank analyses. Results for all metals, common ions and suspended sediment parameters in field blanks were below the analytical reporting limits for 98 percent (469 of 480) of the surface water field blank analytes. Associated results which are less than ten times the RL concentrations have been qualified in the project database. Analytes detected in surface water field blanks included the following:

- Barium was detected in 12.5 percent (2 of 8) of the dissolved field blank samples with concentrations of 0.004 mg/L and 0.008 mg/L (RL = 0.003 mg/L).
- Hardness exceeded the RL (1 mg/L as $CaCO_3$) in 25 percent (2 of 8) field blank samples. Hardness was 2 mg/L in each of those samples.
- Dissolved zinc was detected in 88 percent (7 of 8) of the field blank samples; detectable dissolved zinc concentrations in field blanks ranged from 0.009-0.030 mg/L (RL = 0.008 mg/L).

Sensitivity of field methods for groundwater samples was also determined through deionized water field blank analyses. Results for all metals and common ion parameters in field blanks were below the analytical reporting limits for 100 percent (120 of 120) of the surface water field blank analytes. Associated results which are less than ten times the RL concentrations have been qualified in the project database. No analytes were detected at concentrations above the analytical reporting limits in any groundwater field blanks in 2018.

A.3.5 Precision

A.3.5.1 Laboratory

Laboratory precision was assessed by the relative percent difference (RPD) metric comparing laboratory samples with duplicates. RPD comparisons were made for all analytes measured in this program. Established criteria allow a maximum of 20 percent RPD for water sample results which are at least five times greater than the RL, and 35 percent RPD for sediment samples which

are at least five times greater than the RL. Results of laboratory quality control procedures are available in Appendix B.

A.3.5.2 Overall

The overall precision of surface water, instream sediment, and groundwater sample analyses in 2018 from the SSTOU was assessed with RPD comparisons between samples and paired field duplicates. Established criteria allow a maximum of 25 percent RPD for water sample results at least 5 times the RL, and 40 percent RPD for sediment samples at least 5 times the RL. All associated data which exceeds these criteria have been J-flagged in the project database.

Two surface water sample and duplicate pairs were collected in each quarterly sampling event and these were analyzed for dissolved and total recoverable metals, nutrients, and common ions. Results of RPD comparisons for all metal, common ion and suspended sediment parameters in the field duplicate and field sample pairs were within the established criteria in 99.8 percent (479 of 480) of the sample and duplicate pairs. Field duplicate and field sample pairs with RPD exceeding 25 percent included:

- dissolved cadmium in the sample pair collected at Site SS-14 on March 21, 2018 (RPD = 31 percent).

Groundwater and vadose zone water sample and duplicate pairs were collected during both sampling events and were analyzed for dissolved metals and common ions. Results of RPD comparisons for all metals and common ion parameters in the field duplicate and field sample pairs were within the established criteria in 96 percent (115 of 120) of the sample and duplicate pairs. Field duplicate and field sample pairs with RPD exceeding 25 percent included:

- total alkalinity in Well GW-FR-BG on October 4, 2018 (RPD = 27.5 percent),
- total bicarbonate in Well GW-FR-BG on October 4, 2018 (RPD = 28.6 percent),
- dissolved aluminum in Well GW-FR-BG on October 4, 2018 (RPD >200 percent),
- dissolved iron in Well GW-FR-BG on October 4, 2018 (RPD = 183.6 percent),
- and dissolved manganese in Well GW-FR-BG on October 4, 2018 (RPD = 93.1 percent).

Two instream sediment sample and duplicate pairs were collected in each quarterly sampling event and these were analyzed for total metals in three size fractions. Among all analytes in all size fractions, 528 field sample and field duplicate results were compared and 35 (93 percent) were within the established criteria. Table A-1 presents the sediment field duplicate and field sample pairs which had RPD greater than 40 percent.

Table A-1. Field sample and field duplicate pairs with relative percent differences greater than 40 percent in the Streamside Tailings Operable Unit, 2018.

A.3.5.3 Bias and Accuracy

Bias is defined as directional error from the true value of individual measurements. For field measurements (water temperature, pH, specific conductance, dissolved oxygen [DO] concentration, DO percent saturation, and turbidity), potential bias was addressed through frequent calibration of field instruments documented in calibration logs, and consistent field procedures. For water chemistry and sediment results, potential bias was minimized by adherence to approved field procedures for sample collection and handling, and decontamination of sampling equipment.

Accuracy is the combination of high precision and low bias. Accuracy of laboratory results was assessed by reviewing the analytical method controls (i.e., lab control sample, continuing calibration verification, lab fortified blank, standard reference material) and analytical batch controls (i.e., matrix spike and matrix spike duplicate). Limits established by the laboratory through control charting of each method's performance served as assessment criteria. Any analytical method controls or analytical batch controls that had values outside of the acceptable recovery range were re-analyzed, as detailed in the analytical QC summary provided by Energy Laboratories and included with each analytical summary report (Appendix B).

Report Definitions:
RL - Analyte reporting limit.
MCL - Maximum contaminant level.
ND - Not detected at the reporting limit.
J - Estimated value. The analyte was present but less than the reporting limit.

LABORATORY ANALYTICAL REPORT

Prepared by Helena, MT Branch

Client: MT DEQ-Federal Superfund
Client Sample ID: SS-10A
Project: Silver Bow Creek SSTOU Monitoring
Matrix: Aqueous

Lab ID: H18030365-006
Collection Date: 03/22/18 11:30
DateReceived: 03/23/18
Report Date: 04/17/18

Mercury	0.03	mg/kg-dry	J	0.10	0.00013	SW7471B	04/05/18 14:59 / rgk	04/04/18 09:02	SW7471B	HGCV201-H_180405A	67	41013

Report Definitions:
RL - Analyte reporting limit.
D - RL increased due to sample matrix.
MCL - Maximum contaminant level.
J - Estimated value. The analyte was present but less than the reporting limit.
ND - Not detected at the reporting limit.

Mercury	0.58	mg/kg-dry		0.10	0.00019	SW7471B	04/05/18 14:32 / rgk	04/03/18 09:49	SW7471B	HGCV201-H_180405A	56	40987

Report Definitions:
RL - Analyte reporting limit.
D - RL increased due to sample matrix.
MCL - Maximum contaminant level.
J - Estimated value. The analyte was present but less than the reporting limit.
ND - Not detected at the reporting limit.

Report Definitions:
RL - Analyte reporting limit.
D - RL increased due to sample matrix.
MCL - Maximum contaminant level.
J - Estimated value. The analyte was present but less than the reporting limit.
ND - Not detected at the reporting limit.

Report Definitions:
RL - Analyte reporting limit.
MCL - Maximum contaminant level.
ND - Not detected at the reporting limit.
J - Estimated value. The analyte was present but less than the reporting limit.

- S= Spike recovery outside of QC advisory limits. The recovery in the Laboratory Control Sample was within QC advisory limits. This suggests that the Matrix Spike recover is due to matrix interference.

Qualifiers:
ND - Not Detected at the Reporting Limit
J - Analyte detected below quantitation limits
S - Spike Recovery outside accepted recovery limit
R - RPD outside accepted recovery limits
N - Analyte concentration was not sufficiently high to calculate RPD
A - Analyte concentration greater than four times the spike amount

- S= Spike recovery outside of QC advisory limits. The recovery in the Laboratory Control Sample was within QC advisory limits. This suggests that the Matrix Spike recover is due to matrix interference.

Qualifiers:
ND - Not Detected at the Reporting Limit
J - Analyte detected below quantitation limits
S - Spike Recovery outside accepted recovery limit
R - RPD outside accepted recovery limits
N - Analyte concentration was not sufficiently high to calculate RPD
A - Analyte concentration greater than four times the spike amount

Water - pH acceptable upon receipt?	Yes ☑	No ☐	Not Applicable ☐

Standard Reporting Procedures:

Lab measurement of analytes considered field parameters that require analysis within 15 minutes of sampling such as pH, Dissolved Oxygen and Residual Chlorine, are qualified as being analyzed outside of recommended holding time.

Solid/soil samples are reported on a wet weight basis (as received) unless specifically indicated. If moisture corrected, data units are typically noted as –dry. For agricultural and mining soil parameters/characteristics, all samples are dried and ground prior to sample analysis.

Contact and Corrective Action Comments:

Sample SS-07 nutrient bottle did not have a time, used time from COC. Sample coolers had temperature blanks. Cooler 1 was received at 4.8C, Cooler 2 at 4.7C, Cooler 4.2C, Box 1 at 7.7, Box 2 at 8.1, coolers were received on ice. wj 3/23/18

- S= Spike recovery outside of QC advisory limits. The recovery in the Laboratory Control Sample was within QC advisory limits. This suggests that the Matrix Spike recover is due to matrix interference.

Project: Silver Bow Creek SSTOU Monitoring

ANALYTICAL QC SUMMARY REPORT

Prepared by Helena, MT Branch

Date: *19-Apr-18*

BatchID: R133366

Run ID :Run Order: **ICP2-HE_180326A: 130** SampType: **Sample Matrix Spike** Lab ID: **H18030366-001BMS2** Method: **E200.7**

Analysis Date: **03/26/18 16:56** Units: **mg/L** **Prep Info:** Prep Date: Prep Method:

Analytes 5	Result	PQL	SPK value	SPK Ref Val	%REC	LowLimit	HighLimit	RPD Ref Val	%RPD	RPDLimit	Qual
Potassium	59.9	1.0	50	4.952	**110**	70	130				
Sodium	63.6	1.0	50	8.516	**110**	70	130				

Associated samples: **H18030366-001B, H18030366-002B, H18030366-003B**

Run ID :Run Order: **ICP2-HE_180326A: 131** SampType: **Sample Matrix Spike Duplicate** Lab ID: **H18030366-001BMSD2** Method: **E200.7**

Analysis Date: **03/26/18 17:00** Units: **mg/L** **Prep Info:** Prep Date: Prep Method:

Analytes 5	Result	PQL	SPK value	SPK Ref Val	%REC	LowLimit	HighLimit	RPD Ref Val	%RPD	RPDLimit	Qual
Boron	0.968	0.050	1	0.02198	**95**	70	130	0.933	**3.7**	20	
Calcium	67.0	1.0	50	17.64	**99**	70	130	71.03	**5.8**	20	
Magnesium	54.2	1.0	50	5.066	**98**	70	130	57.98	**6.8**	20	
Potassium	58.0	1.0	50	4.952	**106**	70	130	59.87	**3.1**	20	
Sodium	61.9	1.0	50	8.516	**107**	70	130	63.55	**2.7**	20	

Associated samples: **H18030366-001B, H18030366-002B, H18030366-003B**

Qualifiers:
ND - Not Detected at the Reporting Limit
J - Analyte detected below quantitation limits
S - Spike Recovery outside accepted recovery limit
R - RPD outside accepted recovery limits
N - Analyte concentration was not sufficiently high to calculate RPD
A - Analyte concentration greater than four times the spike amount

Client: MT DEQ-Federal Superfund
Work Order: H18030366

Standard Reporting Procedures:

Lab measurement of analytes considered field parameters that require analysis within 15 minutes of sampling such as pH, Dissolved Oxygen and Residual Chlorine, are qualified as being analyzed outside of recommended holding time.

Solid/soil samples are reported on a wet weight basis (as received) unless specifically indicated. If moisture corrected, data units are typically noted as –dry. For agricultural and mining soil parameters/characteristics, all samples are dried and ground prior to sample analysis.

Contact and Corrective Action Comments:

Cooler 1 was received at 4.8 °C, Cooler 2 at 4.7 °C and Cooler 3 at 4.2 °C. On Ice. Box 1 was received at 7.7 °C and Box 2 at 8.1 °C. No Ice. Time on jar in sample set SLAG-01 is 1540 -Time on COC is 1545. Used time from COC. JCS 03/23/2018

The analyses presented in this report were performed by Energy Laboratories, Inc., 3161 E. Lyndale Ave., Helena, MT 59604, unless otherwise noted. Any exceptions or problems with the analyses are noted in the Laboratory Analytical Report, the QA/QC Summary Report, or the Case Narrative.

The results as reported relate only to the item(s) submitted for testing.

If you have any questions regarding these test results, please call.

Report Approved By:

CLIENT: MT DEQ-Federal Superfund
Project: Silver Bow Creek SSTOU Monitoring
Work Order: H18060190

Report Date: 06/27/18

CASE NARRATIVE

Tests associated with analyst identified as ELI-B were subcontracted to Energy Laboratories, 1120 S. 27th St., Billings, MT, EPA Number MT00005.

All "J" qualified analyte concentrations are below the laboratory minimum recommended Reporting Limit (RL) and above the calculated method detection limit (MDL). Inorganic analytes reported with "J" qualifiers should be verified against the corresponding method blank and continuing calibration blanks. Inorganic "J" quantitations near the MDL may be suspect due to possible method background levels, sample matrix effects, and/or daily variability in instrument signal-to-noise levels.

- S= Spike recovery outside of QC advisory limits. The recovery in the Laboratory Control Sample was within QC advisory limits. This suggests that the Matrix Spike recover is due to matrix interference.

Project: Silver Bow Creek SSTOU Monitoring

ANALYTICAL QC SUMMARY REPORT

Prepared by Helena, MT Branch

Date: *27-Jun-18*

BatchID: 41893

Run ID :Run Order: **ICP2-HE_180620A: 45** SampType: **Sample Matrix Spike** Lab ID: **H18060190-008AMS** Method: **SW6010B**

Analysis Date: **06/20/18 12:31** Units: **mg/kg-dry** **Prep Info:** Prep Date: **6/17/2018** Prep Method: **SW3050 B**

Analytes 6	Result	PQL	SPK value	SPK Ref Val	%REC	LowLimit	HighLimit	RPD Ref Val	%RPD	RPDLimit	Qual

Associated samples: **H18060190-004A, H18060190-005A, H18060190-006A, H18060190-007A, H18060190-008A, H18060190-009A, H18060190-010A, H18060190-011A, H18060190-012A, H18060190-013A, H18060190-014A**

- S= Spike recovery outside of QC advisory limits. The recovery in the Laboratory Control Sample was within QC advisory limits. This suggests that the Matrix Spike recover is due to matrix interference.

Run ID :Run Order: **ICP2-HE_180620A: 46** SampType: **Sample Matrix Spike Duplicate** Lab ID: **H18060190-008AMSD** Method: **SW6010B**

Analysis Date: **06/20/18 12:35** Units: **mg/kg-dry** **Prep Info:** Prep Date: **6/17/2018** Prep Method: **SW3050 B**

Standard Reporting Procedures:

Lab measurement of analytes considered field parameters that require analysis within 15 minutes of sampling such as pH, Dissolved Oxygen and Residual Chlorine, are qualified as being analyzed outside of recommended holding time.

Solid/soil samples are reported on a wet weight basis (as received) unless specifically indicated. If moisture corrected, data units are typically noted as –dry. For agricultural and mining soil parameters/characteristics, all samples are dried and ground prior to sample analysis.

Contact and Corrective Action Comments:

Cooler 1 was received at 1.0 °C, Cooler 2 at 3.0 °C, Cooler 3 at 0.9 °C, Cooler 4 at 1.4 °C. One Ice. Box 1 was received at 19.5 °C, Box 2 at 18.0 °C. No Ice, and no temperature blank. JCS 06/08/2018

ANALYTICAL SUMMARY REPORT

The analyses presented in this report were performed by Energy Laboratories, Inc., 3161 E. Lyndale Ave., Helena, MT 59604, unless otherwise noted. Any exceptions or problems with the analyses are noted in the Laboratory Analytical Report, the QA/QC Summary Report, or the Case Narrative.

The results as reported relate only to the item(s) submitted for testing.

If you have any questions regarding these test results, please call.

Report Approved By:

CLIENT: MT DEQ-Federal Superfund
Project: Silver Bow Creek SSTOU Monitoring
Work Order: H18060191

Report Date: 07/06/18

CASE NARRATIVE

Tests associated with analyst identified as ELI-B were subcontracted to Energy Laboratories, 1120 S. 27th St., Billings, MT, EPA Number MT00005.

All "J" qualified analyte concentrations are below the laboratory minimum recommended Reporting Limit (RL) and above the calculated method detection limit (MDL). Inorganic analytes reported with "J" qualifiers should be verified against the corresponding method blank and continuing calibration blanks. Inorganic "J" quantitations near the MDL may be suspect due to possible method background levels, sample matrix effects, and/or daily variability in instrument signal-to-noise levels.

Report Definitions:
RL - Analyte reporting limit.
MCL - Maximum contaminant level.
ND - Not detected at the reporting limit.
J - Estimated value. The analyte was present but less than the reporting limit.

LABORATORY ANALYTICAL REPORT

Prepared by Helena, MT Branch

Client: MT DEQ-Federal Superfund
Client Sample ID: SS-13
Project: Silver Bow Creek SSTOU Monitoring
Matrix: Surface Water

Lab ID: H18060191-010
Collection Date: 06/07/18 16:15
DateReceived: 06/08/18
Report Date: 07/06/18
